THIS is the beautifully situated residence of Raymond de la Poer, Esq., D.L., the present high sheriff of the County Kilkenny, and himself a warm friend and patron of horticulture generally. Sojourning at the popular watering place of Tramore, I was recommended to see Kileronagh, "an unpretentious place some dozen miles distant on the Kilkenny side of Waterford, where some lessons may be learned, and where most things in the gardening way are well done." After returning I must say the description is correct, and I will briefly refer to what came under my notice. The residence is very venerable looking, surrounded by many kings of the forest that have seen many summers come and go, and is approached by a carefully kept winding avenue and small lawn neatly mown. Many improvements have been made by the present owner since the estate came into his possession, from an Italian named Bartolucci, now dead some time. This latter gentleman had some eccentric ideas of improving a garden, for he was in the habit of carting the surface soil away to top-dress the lawn. The most recent was the rebuilding of an extensive pentagonal conservatory, not yet completed, to contain chiefly Tree Ferns, warm house Palms, all the better foliage plants, such as *Dracenas*, *Caladiums*, foliage *Begonias*, *Dieffenbachias*, *Anthuriums*, *Crotons*, *Pandanus*, *Musas*, together with an assortment of flowering greenhouse and stove plants and climbers. As yet there are but a few specimens of the former, chiefly Palms, Cycads, and Tree Ferns, too tall for the other houses, accommodated here, as the ornamental and encaustic tiling and fixtures are not yet completed, so we pass out to the lawn, flower and sub-tropical garden, passing the numerous tennis and other courts, to have a look at the hardy *Azalea* and *Rhododendron* beds, where numerous groups of Lilies, especially *L. auratum*, with *L. lancifolium* in variety; *L. tigrinum*, single and double; *L. eroceum*, *L. Martagon*, and all the turn-cap section; *Hemerocallis*, *Alstromerias*, *Hyacinthus eandicans*, and numerous allied plants and flowers have seemingly found a happy home. The majority of the *L. auratum* had fifty and sixty blooms, and exhibited a vigour never noticed in pot-grown Lilies. They have been there untouched for some years. The soil was chiefly peat, and they received no petting, so those who fail to grow or maintain in vigour this magnificent Lily had better take the hint.

In other beds were numerous plants of the hardy Mediterranean Heaths, *Ceanothus rigidus*, *Desfontainia spinosa*, *Berberis stenophylla*, *Benthamia fragifera*, *Escallonia Ingrami*, *Weigela amabilis*, *Hypericum*, *Forsythia suspensa*, *Eurybias*, and a large selection of *Spiraeas*, *Rubus*, *Prunus*, &c., all seemed healthy and happy. It is only fair, however, to say they are admirably protected from all injurious winds by judicious planting. On our way to the Rose garden we pass a remarkable basket bed that at once arrests attention, about a dozen feet in

diameter. There were four shelving concentric circles, one above another, the centre on the top being occupied with a fine-foliage *Aralia*; then came in succession tricolor *Pelargoniums*, *Fresine Lindeni*, Tuberous *Begonias* in alternate colours, and lastly variegated *Periwinkle*, acting as fringe and drooping gracefully to the ground. If any reader wants the constituents of an effective lawn basket bed I commend this as very effective. The foliage and succulent plants, *Castor Oil*, *Tobacco plants*, *Cannas* (twelve varieties), *Gladioli*, and *Funkias* are each passed, and generally having separate beds, and we reach the Rose garden. Hundreds of *Roses* of all sections are grown here, and though every attention is paid, various stocks tried, and some grown on their own roots, still the vast majority seem not happy, nor even as fairly healthy as I should have expected. The head gardener, Mr. Crawford, who kindly escorted myself and gardening friends, tells us they enjoy excellent health for two years, and then decay's effacing fingers become only too apparent. Even when grown in the old soil of a Vine border equally with maiden loam, which seems fairly good, the result is much the same in the vegetable and fruit gardens as on the lawn. With the dwarfs the usual stock is the *Manetti*, but on their own roots the result is much the same. At present a large square is being budded on the seedling *Manetti* with the view of securing more vigour. Yet all the *Teas*, *Maréchal Neil* also, are grown against walls, and on the whole seemed doing best. The climbers on the dozen arches in the Rose garden were very effective a month since.

Anything in the nature of bedding out is not this season aimed at, but the numerous borders on the lawns, and the mixed borders walled in, are replete with the usual good plants. There is a small rock and alpine garden exclusively reserved for the proprietor, but I was unfortunate in not finding him at home to learn many facts of his specialities, which seemed to contain many things rare and not often found in private gardens.

Approaching the garden proper we pass the Melon pits and have a look at the fruits and the system of growth. The two principal varieties depended on are *Blenheim Orange* and *Laurie's Beauty*; the former is well known; the latter Mr. Crawford finds as hardy and useful as *Munro's Little Heath*, though I have never seen it elsewhere. He has another, named *Hampstead Park Seedling*, under trial, and so far it is most encouraging. No artificial heat has been used for two months, and the fruits continue to "set" and to grow on luxuriantly. The same applies to the Tomato pit, beds and banks of stable manure being used to start the plants, and sun heat being solely depended on afterwards, due precaution being taken to close early so as to imprison as much thereof as possible. Within memory, probably, no warmer June came for this purpose. The varieties found to do best are *Dedham Favourite*, *Perfection*, and *Hathaway's Excelsior*. I find that vigorous early growth and not too much moisture are here the best antidotes against *Peronospora*. In fact those planted on the back wall of my greenhouse are never watered, and my only complaint is that they are too vigorous. Adjoining are the Marrows (*Muir's Prolific*) and Gourds, if anything too vigorous.

High Pressure Water Supply.—What an economy, as well as convenience, nay a blessing, would this be in every garden, not merely for the proprietor, but for the garden hands, but still more for the plants. There was nothing of the kind here until the advent of Captain de la Poer, and now a hose can be turned on any part of a garden of about 4 acres, or the numerous houses therein, and one man can quickly do the work of at least five. This is secured by connecting a force pump, worked by a pony or donkey, with a passing stream or millrace, and filling a 5000 gallon tank on the top of one of the out offices. There the water, if not already soft, is fully exposed to the sun, and a few leading lines of piping take it all over the garden and houses. A hydraulic ram, if feasible, might even be cheaper, but where possible no proprietor would think of reverting to the obsolete system of dragging (often hard water) in cans or barrels, by the garden employés.

The Vegetable Department.—I cannot say whether it is good culture, good varieties, and judicious and timely planting, or the assistance of the already mentioned soft water supply that accounts for the excellence of what came under our notice (probably all four combined), but my friends and I have rarely seen finer; and Mr. Crawford agrees with most good gardeners in thinking this department of their responsibility should not be the weakest. Just a few references. Carrots.—Rust and grub spoil what escapes the wireworm only too frequently. Here an effectual antidote is found to be a dressing at the time of planting the seed of burnt refuse mixed with fresh soot. The varieties, after various trials, remain *Summer Favourite*, *James' Intermediate*, and *Carters' Perfection*. Beans.—B. S. Williams's *Earliest* has here superseded the old prolific *Mazagan*. Peas.—Among dwarfs *Stratagem* is still unrivalled for size of pod and quality. The others preferred of a dozen varieties grown are *Veitch's Perfection*, *Telephone*, and *Laxton's Supreme*. Potatoes.—When Mr. Crawford came here, more than a dozen years since, his first effort was to secure a Potato (variety of *Myatt's Ashleaf*) he became acquainted with in the Duke of Sutherland's gardens at Dunrobin as likely to specially suit this soil. Yielding to few in my knowledge of Potatoes, and having tested both the quantity and quality of this strain, I must say after thirty years' experience I know of no recent introduction to excel it. Every other vegetable seems well cared for and made the most of.

The Fruit Garden.—Like most other gardens this year the falling away is considerable from years past. Though a few of the *Codlins* and *Pippins*—notably *King of the Pippins* among the Apples, and the *Duchess* and *Beurré Diel* among Pears—bear a limited crop, on the

whole all suffered seriously from the hurricane that swept the flowers away at the time of fertilisation. The heaviest crops generally were among bush fruits and Strawberries; in fact the crop of Gooseberries still is enormous, and after a month's gathering every day the best of Elton Pine was collected to-day among the Strawberries. Figs do well outdoors. All the older varieties of Strawberries bore full crops; they were heavily mulched, but many of them are to be discarded for Laxton's Noble, Pioneer, King of the Earlies, and A. F. Barron. I can only ask space to name the collections of Primulas, Cinerarias, Lilliums, Gladioli, Tuberous Begonias; or the three remarkable hedges of Lavender, Clematis (twenty varieties), and Sweet Pea, each 50 yards long, worth going a long distance to see.

The Early and Late Vineries.—In the former the Black Hamburgs and Raisin de Calabre are advancing and colouring rapidly. Though young ones they bear heavy crops. Very seldom, too seldom, is the second named seen, though the bunches and berries are generally very large. No bunch here will be under 12 lbs. In the later house the Muscats are all that could be desired, and though free from insects or disease, Mr. Crawford would not recommend under any circumstances they should be planted outdoors as here. He thinks they should be inside and wholly under control.

The Store and Forcing Plant Pits.—Here are many of the large specimen plants that have won the first prizes wherever shown, such as Palms, Dracenas, Crotons, large Adiantum farleyense, A. concinnum, A. cuneatum, and the Gold Fern, none less than 3 feet high, and more across. I cannot hope for space to name the several varieties of Acalyphas, Marantas, Sonerilas, Dieffenbachias, Eranthemums, tall Pandanus, Aralias, Dicksonias, Scaforthias, Gleichenias, Davallias, and a select collection of Orchids. The roof is covered by Stephanotis, Kennedys, Passifloras, and Bignonias. Rather curious, where all are so well done, the fine Eucharis Lily, after repeated experiments, should fail, notwithstanding being repotted, cleaned, and washed in petroleum. I have recommended Mr. Crawford to try a higher temperature.

The Greenhouses and Cool Range.—After the length to which these notes have extended I shall confine myself to merely naming a few striking good things. Here for the first time I found Bougainvillea glabra flowering profusely in a house without any artificial heat for months past. Many of the finer kinds of Lilliums are now blooming profusely, and a specialty very telling was the use made of such foliage plants as Acacia lophantha, Grevilleas, small Palms, Aralias, Ferns, and hardy Dracenas and Cordylines among such flowering plants as the better kinds of Cannell's round-flowered Pelargoniums and Tuberous Begonias, Abutilons, Fuchsias, Gloxinias, Clivias, Polygalas, Salvias, Sparmannias, and a host of the customary greenhouse plants. The custom is to neglect the greenhouse at this time, there is so much to attract outdoors, but here is an effective method of decoration.

The Chrysanthemums.—From here in many former years came the first prize winning stands at Dublin, Clonmel, Waterford, and elsewhere. It is painful to think that for some reason or reasons not satisfactorily explained, at the final potting from the 6 to the 10-inch pots, the 400 plants grown—then all in splendid condition—sustained a check, resulting in the loss of lower leaves, roots, &c., and from which it is hopeless to think they can now recover, for show purposes. Permit me in conclusion, on behalf of myself and friends, to warmly thank Mr. and Mrs. Crawford for the courteous and hospitable attentions we received.—W. J. MURPHY, Clonmel.

ABOUT SPARROWS.

IN the first place, I cannot understand why it is this particular bird is so continually held as useful to the farmer and gardener, in comparison to the injury it does. For more than fifty years I have had the sparrows under observation, either in town or country; and I have come to the conclusion that in the country I would very much rather be without them; and I only wish that those epicures, so-called, who delight in lark puddings and stews, would, instead of these delightful songsters, substitute the sparrow, which is really deliciously appetising. I never, at civic or other feasts, partake of larks, on principle.

It is said that at the breeding season the sparrow feeds its young entirely on caterpillars and other insects. From long and continued notice of the habits of the bird, I must deny this. In many instances, when the insects have been scarcer, the sparrow has taken the bloom buds out of my Gooseberry bushes, Plum trees, and even the White Thorn. I know very well the so-called sparrows' friend will argue there was an insect in the bud. This I proved again and again to be not the case, for when I put nets to keep the sparrows off over some, as a test, I found the bushes healthy and fruitful. They picked off my Crocus blooms by the hundred, my Polyanthus, my Primroses, and some Hyacinths in their wantonness, for I have again and again seen them hopping round the plants, picking them and tossing them down. When I fed my birds they drove away the hedge sparrows, the tits, wagtails, and other insect-eating birds; they attacked and drove out of the nest-boxes my starlings, and are the worst enemies in this way that martins and swallows have. In these ways they did me infinite harm during the vaunted breeding season. But I am bound in all justice to say that when aphides were about they were most industrious in searching them out; but then, this same work would have been well done by other and soft-billed birds they had driven away, such as I have mentioned; also whitethroats, robins, wrens, &c., which birds do not feed on corn and seeds of large size. The sparrows pecked off the Peas as soon as they

appeared above ground, spoiling row after row. They ate the new-sown seeds of the Radishes, and the young plants as soon as they appeared; and so with Lettuce, besides much other damage; and all this in the spring.

This is all apart from the immense damage they do the farmer in the autumn in what they eat and spoil of his corn; and yet I am told to uphold the sparrow, and to try and persuade people of its "all goodness." I cannot do it conscientiously, so I will not attempt it. I have said the sparrow is a pest, and I maintain that it is. A writer is quoted in these words:—"We see them every minute of the day in continual progress, flying from the nest for a supply, and returning on rapid wing with gnat or caterpillar." I do not value this evidence in the least degree. I have had sparrows' nests under close observation during the time of feeding the young, and I have never seen them bring a gnat. It is not their class of insect food. This is a slovenly way of writing; gnats come out during evening, when martins and swallows take them. People generally are not alive to the fact, and I find many naturalists the same—because some birds feed on insects they will eat all kinds. Each variety has its particular food, and a locality may be swarming with one particular kind of insect, and yet some varieties of birds would be dying of hunger in their midst. This is so. Yet people are continually writing about the good birds do, without the requisite knowledge of which, how, when, and where, and in what way. I am asked often how to get rid of slugs from the garden. I answer, "Put a duck or two in." "Oh, but," say they, "we have lots of birds." But no birds but ducks eat white slugs, and so they "leave it to the birds," and the slugs reign supreme.

It is quite immaterial to me whether others like to have their gardens and fields denuded of produce by the sparrow. If they prefer it, be it so. I have only stated what I personally know to be facts.—HARRISON WEIR, Sevenoaks.

CARNATION EXHIBITIONS.

IN Mr. R. Dean's article on "Carnation Exhibitions" in your last issue he says it is matter for wonder that we do not see better flowers staged at country shows. Well, I think one great reason is the poor prizes which are given compared with those which are offered for Roses, Dahlias, and other florists' flowers. For instance, at the Liverpool Show the first prize for eighteen Roses is 30s.; for eighteen Carnations and Picotees it is 10s. Then at the Shrewsbury Show the first prize for twelve Carnations is 7s. 6d., at Burton it is 10s., and at Salisbury 10s. In fact, there is only one general show I know where good prizes are offered for Carnations and Picotees, and that is Leicester. There they always have fine flowers, finer in fact than are seen at some so-called national shows. That clearly proves that where prizes are offered which will pay expenses they will secure good exhibitors and *vice versa*, and I think if show committees were to offer better prizes there would soon be an improvement in the quality of the flowers staged. There is one other particular, which other flower shows might copy from Leicester, and that is to fix a time for staging, and keep to it. At too many shows you find a time—say 11.30—fixed, and instead it is nearer 1.30 when the exhibits are all staged. Then the judges have to hurry over their work, and it is often only half done in consequence.—ARTHUR R. BROWN, Handsworth, Birmingham.

THE PARIS EXHIBITION.

THE JAPANESE GARDEN AT THE TROCADERO.

VISITORS who, on entering the Exhibition by the Jéna gate, follow the avenue of Chestnut trees, regard with curiosity a space enclosed by a palisade of Bamboo, at one of the corners of which, supported by a high pole, floats an enormous white flag with a large brown disk. There is the spot set apart for Japanese horticulture, worthily represented by Mr. Kasawara, horticulturist at Tokio, who has converted this corner into one of the most curious, as it is also one of the most frequented parts of the gardens. The ground being on a somewhat inclined slope the enclosure is approached by a rustic flight of steps, the stakes and the trunks of trees forming the steps, being placed vertically. For that the heavy trunks have been cut into rounds, 20 centimètres* in thickness, and the small ones are simply driven into the earth as stakes. The landscape park is arranged to give an idea of the taste which presides at the making of gardens in Japan, descriptions of which have been brought back by travellers. We find a small sheet of water with a zigzag outline, and an island 2 square mètres in area. In order to retain the water they have placed, touching each other, posts of different heights and sizes. On the borders of this sheet of water, which is surrounded by a narrow belt of grass, are scattered some Pinuses, Thuiopsis, Biotas, Cycas revoluta, Chamerops, &c. On the right is a slight construction in Bamboo (this is the only wood employed) covered with mats made of reeds and open on both sides. Exquisite tea is served here, and they sell also certain Japanese products, Japan vases, baskets, &c. We notice also certain kinds of suspensions formed of one or several rings decorated with moss, on which are affixed rhizomes of Davallia bivalata. The fronds growing on the surface of these contrivances produce a very original effect.

The second portion of the ground devoted to the culture of various plants is divided into two parts separated by a slope of 1 mètre necessi-

* About 8 inches; a mètre is equal to 39.37 English inches.

tated by the configuration of the ground. Chrysanthemums and Lilies are the most important. Amongst these last we remark chiefly those for which we are indebted to the Japanese. There are certain Lilies which European horticulturists cannot multiply, the bulbs diminishing in volume every year, and only producing plants less and less strong. Bulbs are therefore brought from Japan every year in large quantities. *Lilium auratum*, *L. speciosum*, and its varieties, *L. Kretzeri rubrum* and *L. Krameri*. It is the same with the *L. Leichtlini*, *L. cordifolium elegans* or *Thunbergianum*, *L. odorum*, commonly called *L. japonicum Colchesteri*, &c., which are imported on a much smaller scale. *Pæonies* and *Caladium esculentum* are also objects of well conducted culture.

But the principal curiosities of the Exhibition of Mr. Kasawara are the trees and shrubs in a dwarfed form cultivated in Japan vases for fifty and one hundred years. Trees which in our parks attain from 10 to 20 metres (about 11 to 22 yards) in height are kept in bowls from 50 to 60 centimetres (about 20 to 24 inches) in height with distorted branches, stunted by age. A just idea can then be formed of the difference between our taste and that of the Japanese, who have a marked predilection for everything which is little, and with whom diminution is synonymous with perfection.

Amongst the most interesting of these plants are *Rhynchospermum jasminoides*, *Juniperus chinensis*, *Pinus parviflora*, *Osteomeles athyldifolia*, *Thuia obtusa*, *Ginkgo biloba*, *Podocarpus (Nageia) rotundifolia*, *P. macrophylla*, *Damnacanthus indicus*, *Nandina domestica*, *Quercus cuspidata*, *Dendropanax japonicus*. Some *Acers* of the Japanese Maple series, *A. palmatum*, *A. japonicum*, *A. trifidum*, *A. pietum*, &c., are added to the list. All these plants are reared and cultivated with manures in Japan vases, which would be a delight to many small amateurs. We have still to mention a little conservatory in which are exhibited specimens of the small *Dendrobium moniliforme*. They altogether give the spectator a good idea of this miniature nature which the Japanese love and which forms the basis of their gardening art. The specimens, with few exceptions, were brought from Japan at great expense. This was quite useless, as M. Kasawara might have found in France cheap plants from his country to form the foundation of his garden plantation. He would then have had nothing more to do but exhibit his dwarfed trees to add the picturesque to the predominant vegetation. Many of his plants died on the passage from Yokohama to Marseilles, which has been a great loss to the importer, and we doubt much whether the sale of the survivors will be productive, the taste for these curiosities being little spread in France. However, it may be the attempt made by this horticulturist, who has come so far, is worthy of praise.—(*Revue Horticole*.)

LA FRANCE.

THIS is one of my chief favourite Roses, consequently I have a good number of plants, and have been enjoying a plentiful supply of flowers during the past two or three weeks. There has been considerable difference this season between the early and the late flowering of this Rose, which I do not remember to have remarked so particularly before. In June and July comparatively few blooms were produced, and these were very poor, wanting in substance, colour, and fragrance, so that we were forced to the conclusion that *La France* was degenerating, and that it would have to be superseded. Early in August, however, the second flowers were produced, and there was such an agreeable change in their character that our hopes were restored. They assumed their usual form, the fragrance was exquisite, and the colour very much darker than ordinary—considerably darker, and richer in fact than I remember observing them before, and much in the way of a new variety of this type that was brought into notice a year or two since. Some of the early and half-formed flowers were followed by seed pods, and on one plant I have now half a dozen large fruits ripening fast. Have any good varieties been raised as seedlings from *La France*?

ROSES FROM CUTTINGS.

It is so easy to increase most H.P. Roses from cuttings in the open air that it is not surprising many have been induced to add to their stock in this way. Some time since I raised a number in this way with only a fair per-centage of losses, and the plants so obtained made rapid growth, and for three or four years prospered greatly. Now I can see too evident signs of deterioration that extra attention has failed to check, and it seems unless there is some surprising change that another season they will be little good. There are a few well marked exceptions to this, and one of these is the variety *John Hopper*, and so far from deteriorating this is becoming even more vigorous and floriferous than before. I have noticed the failing more especially amongst the dark Roses, all in my collection, except perhaps *Charles Lefebvre*, giving indications of weakness.—SURREY AMATEUR.

GRAND MOGUL AND JEAN SOUPERT.

A WELL-KNOWN Rose authority has submitted flowers, wood, and foliage of the above two varieties for comparison. In the case of

Grand Mogul the flowers are of good shape and substance, and brighter in colour, with more scarlet in the edges and under side of the petals, than *Jean Soupert*. The leaves are rougher, duller, more crumpled, and the spines much larger. There is a noticeable difference in the leaves, for those of *Jean Soupert* are flatter, smoother, and the pinne more acute, the spines being considerably smaller than those of Grand Mogul. Further, it is stated that *Jean Soupert* rarely produces a good bloom. The varieties are admitted to be near each other in floral characters, but it is contended that Grand Mogul is a better Rose, and this is borne out by the specimens placed before us.

REVIEW OF BOOK.

The Uses of Plants: a Manual of Economic Botany. By G. S. BOULGER, F.L.S., F.G.S. London: Roper & Drowley, 11, Ludgate Hill. 1889.

MUCH has been contributed in recent years upon the subject of economic botany, and exhaustive works have appeared dealing with the subject in various aspects. The museums at Kew containing such extensive, well-arranged collections, and the guide books issued in connection with them have drawn public attention to the numerous products of the vegetable kingdom, and conveyed a great amount of useful information. The book under notice seems intended to give an epitome of the knowledge gained in the past fifty years, but we should have wished that it had been more fully treated, as a good portion of the work is little more than a catalogue. It opens with a review of economic botany more than fifty years ago, and this is followed by a chapter on the progress of economic botany during the past half century (1837 to 1887), both of which are introductory to the principal portion of the book. This is in ten parts, dealing with foods, materia medica, oils, gums, dyes, fibres, timbers, &c.

We extract the following portion of the introduction to the chapter on foods:—

"In no class of our wants is our dependence on the vegetable kingdom so strikingly seen as in our food. With the exceptions of water and salt, all our food is, either directly or indirectly, of vegetable origin.

"There is hardly any class of plants, or any part of the plant, that has not contributed in some form to our food supply. Ferns, Mosses, and Club Mosses afford little or no nutrient matters; but, not to speak of candied Violets and Rose petals, the fleshy corollas of the *Mahwa* (*Bassia latifolia*, *Roeb.*) form an important article of diet to men and animals in India, and have been imported into this country for the latter; whilst in the genus *Typha*, of which the common Reed-maces are well-known British species, even the pollen has been employed, both in *Scinde* and in *New Zealand*, as a bread-stuff. The stigmas of the *Saffron Crocus* (*Crocus sativus*, *Bert.*), the cultivation of which in *England* is extinct, and the unopened flower buds of the *Clove* (*Caryophyllus aromaticus*, *L.*) and the *Caper* (*Capparis spinosa*, *L.*), the fleshy peduncles of the *Fig* (*Ficus Carica*, *L.*), or the *Cashew-nut* (*Anacardium occidentale*, *L.*), and the succulent bases of the bracts in the inflorescence of the *Globe Artichoke* (*Cynara Scolymus*, *L.*), are other instances of the employment of unusual structures as food.

"In this department of vegetable technology the most striking feature in the progress during Her Majesty's reign is, perhaps, the results of the vastly increased facilities of transport, steam navigation having rendered distant lands tributary, even of their fresh produce, to our population, which has so long outgrown its home supplies of the necessaries of life. In this way many perishable articles have now found their way even into the market of our streets; whilst many improved processes have added largely to our supplies of preserved fruits and vegetables. In 1882, for instance, we imported in all 64,240,749 cwt. of Wheat, of which 24,500,000 cwt. came from the United States, 11,000,000 from India, 3,000,000 from Canada, and more than that amount from Russia, besides 52,000,000 cwt. of other corn. Owing to the continuous reduction of virgin land into cultivation in the far west of Canada and the United States, the exporting capacities of these countries are rapidly increasing, whilst increased railway communication so facilitates this export that it is stated that Wheat, which is said to cost 40s. a quarter to grow in *England*, may possibly be delivered in *Liverpool* in a very few years at 23s. We are at present importing Potatoes most largely from France; but of raw fruits our supplies are drawn from Malta, the Azores, Canaries, Madeira, the United States, and even the West Indian islands. Thus in 1878 the Azores alone shipped over 410,000 boxes of Oranges, each containing 400, to *England*; and in 1882 we imported in all over 4,250,000 bushels of Oranges and Lemons. In 1886 we imported 3,261,460 bushels of raw Apples, of which 1,647,052 came from the United States, whilst of the raw fruit 'unenumerated' imported during the same year, 906,000 bushels came from Spain.

"In 1837 Pine Apples were almost exclusively home-grown, and, necessarily, expensive; but, writing in 1854, the late Professor Archer says:—'The importation of Pine Apples from the Bahamas has now become an extensive trade; more than 200,000 were imported in 1851. . . . For export to Europe it is gathered before it is quite ripe, and usually reaches *England* in pretty good condition. The English grown Pine Apple usually is from 10s. to 12s. per lb., while the imported ones rarely exceed half-a-crown for the whole fruit.' In 1867 this fruit was first exported from St. Michael's, in the Azores, 427 fruit being despatched in that year. Much capital was then invested, and in 1875-76 over 34,500 were sent out. Since then the trade has so in-

creased that those islands, with the Madeiras and Canaries, now afford us our chief supply, though, by the use of refrigerators, they are now brought from the West Indies. Fruits of various kinds, especially Peaches and Apricots, having been exported in syrup from the United States, mainly since 1867, the preservation of the Pine Apple in this manner was first carried out at Nassau (Bahamas) in 1874.

"Similarly, the trade in Bananas, of which fruit only 564 bunches were imported from St. Michael's in 1879, has enormously increased, though nothing more has been heard of the 'Plantado passado,' or dried Plantain fruit, recommended by Mr. P. L. Simmonds in 1854. The Plantain (*Musa paradisiaca*, L.) and the Banana (*M. sapientum*, L.) are generally considered distinct species, but vary so as to defy discrimination. They produce far more food, in proportion to the space they occupy, than any other plant. One Banana plant will yield three bunches, each weighing 44 lbs. in the year, which is equal to 140,000 to 400,000 lbs. on three acres. Thus the same area that yields 33 lbs. of Wheat, or 99 lbs. of Potatoes, will produce 4400 lbs. of these fruits. Mr. Simmonds calculated that the almost imperishable food substance referred to could be sold in London at 3d. a lb. Professor Church speaks of the Banana as 'a nutritious food, having less water and more nitrogenous matter than is commonly found in fresh fruits. It contains, when ripe, much sugar, but very little starch.'

"As in many other departments of the present inquiry, the progress made in the half-century can be to a great extent gauged by a comparison of the articles now in commercial use with those reported upon at the time of the Great Exhibition of 1851. Undoubtedly the greatest change that has taken place in our food supply, so far as derived from the plant world, during this period, is the enormously increased consumption of Maize, and the introduction of glucose, which is largely prepared from it. No doubt our consumption of many fresh vegetables and fruits, of Asparagus, Tomatoes, Spinach, Artichokes, and Mushrooms, has increased more than proportionally to the increase of population; but this has been mainly met by more extensive home market gardening, and has not seriously affected our imports. The extension of the cultivation of Maize throughout Asia, Africa, America, and Southern Europe has been mainly the work of the last 150 years. It is cultivated with less labour, probably, than any other cereal. Prior to the Potato famine of 1846 Maize was not a regular article of British commerce. In 1847, 3,614,637 qrs. were imported; in 1850, 1,286,263 qrs.; in the first eight months of 1876, 27,000,000 cwt.; and in 1886, 31,000,000 cwt. Of this last amount, 16,700,000 cwt. came from the United States, and 7,576,612 cwt. from Roumania. The removal of legislative restrictions has led to its employment in large quantities in malting, as well as in cattle-feeding. Many preparations of Maize are also popular articles of food, such as corn-flour, oswego, and maizena. It is poorer in flesh-formers than Wheat, but richer than Rice, and it contains more oil than any cereal; but 64½ per cent. of its composition is starch. It cannot be relied upon to ripen its grain in England; but may sometimes answer as a fodder-crop, the young stems being very rich in sugar, and yielding in warmer climes from 50,000 to 80,000 lbs. of green fodder per acre. In Brittany it forms a useful autumn crop on sandy soil too poor for Clover or Lucerne. Three-fourths of the Maize produced in the United States is grown within 450 miles of Springfield, Illinois. In the Western States it is sometimes grown as the cheapest form of fuel. It was not until 1853 that glucose was prepared by treating the starch with dilute sulphuric acid, which has afterwards to be neutralised and removed as sulphate of lime. In 1881, 11,000,000 bushels of Maize were converted into glucose in the United States. In 1885 there were in Germany about fifty factories engaged in the manufacture of glucose, mainly from Potato-starch, in which 10,000 tons of 'hard' sugar, with little dextrin present; 20,000 tons of 'syrup, with much; and 1250 tons of 'colour,' or glucose burnt to caramel, were produced. It can be produced at half the price of cane-sugar, and is mainly used in brewing and confectionery. In 1886 we imported 502,567 cwt., of which 441,374 cwt. came from Germany."

HORTICULTURAL SHOWS.

READING.—AUGUST 28TH.

BRILLIANT weather favoured the autumn Exhibition of the Reading Horticultural Society on the above date, but the heat was not so great as to be oppressive, hence an excellent display could be inspected without discomfort. Few shows are held in a more agreeable situation than that in the pleasant town famed for seeds and biscuits. The Forbury Gardens at Reading are admirably laid out with smooth lawns, cheerful flower beds, and shady walks, and within these gardens are the Abbey ruins—huge massive walls. The Show is held amongst the ruins, by permission of the Mayor and Corporation of the town, a canvas covering stretching from wall to wall shielding the exhibits. The interior is delightfully cool and abundantly roomy, while sloping turf-covered banks enable the exhibits to be arranged in the free informal manner that is alone consistent with true effect. Last year the Committee moved in a new direction by coupling with the Show an evening illumination of the gardens, adding the further attraction of a good band, and the result was so satisfactory that it was repeated this year with equally good results.

The Show this year was a marked improvement on any of its predecessors. To begin with, the entries were far more numerous, indeed the entry fees showed an excess of £12 over last year's amount, and as the gardeners in the home and adjoining counties know their business as

well as those in any part of the kingdom, there was quality as well as increased quantity to note. There was perhaps a slight falling off in specimen plants, a sign of the times which has been noted at other shows, but groups, flowering plants, and cut flowers were better than ever, fruit an enormous improvement, and vegetables fully equal to the very high standard of last year. It may be well to begin with what was perhaps the greatest feature of the Show.

FRUIT.

There was a splendid display of Grapes, both black and white. Peaches and Nectarines were very good. Plums were excellent, and Apples in advance of what might have been expected from the season. Black Hamburgh Grapes (three bunches) were shown by seven growers, so that there was plenty of competition, and the quality was of a high order. The first prize bunches came from Mr. Lane, gardener to Miss J. D. Smith, Ascot; they were excellent clusters, well ripened and coloured, but a little rubbed. Mr. Bowerman, gardener to C. Hoare, Esq., Hackwood Park, was a good second with medium sized, well ripened bunches carrying a good bloom. Mr. Turton, gardener to G. Hargreaves, Esq., Reading, third with irregular bunches; berries good, but imperfectly coloured; and Mr. Ashman, gardener to J. Crews, Esq., Billingbear, was deservedly commended; the berries were small, but well ripened, and the bunches very large. There were nine competitors with any other black, and Mr. Waite, gardener to Col. the Hon. W. P. Talbot, Esher, of vegetable growing fame, won with a trio of capital bunches of Madresfield Court. The berries were a little irregular in point of size, but the bunches were very large and well formed, the fruit carrying a beautiful bloom. Mr. Osman, gardener to Sir E. Colebrook, Bart., Ottershaw Park, was second, his fruit a little lacking in colour, but the bunches good. Mr. Robins, gardener to E. D. Lee, Esq., Hartwell House, was third with finely ripened but rubbed fruit; and, to show the excellence of the competition, it may be added that extra prizes were awarded, very deservedly, to Mr. Cakebread, gardener to Sir P. Rose, Bart., Rayners, and Mr. Ashby, gardener to Mrs. Fanning, Whitechurch.

Of Muscat of Alexandria (three bunches), there were eight capital lots, forming an excellent class. Mr. Lane was first with superb clusters, the bunches of medium size, and the berries possessing the clear amber hue indicative of perfect ripening. Mr. Ashby was second, his clusters were enormous, but not perfectly ripened, the same remarks applying to the third prize lot of Mr. Cakebread. Again extra prizes were deemed necessary to do full justice to the exhibits, one being awarded to Mr. Currey, gardener to Col. Pepper, Salisbury, and another to Mr. Maher, gardener to A. Waterhouse, Esq., Yattendon. Eight also entered with any other white kind. Mr. Ashman won with very fine bunches of Buckland Sweetwater; Mr. Currey second with the same variety, berries small, but well ripened, and Mr. Maher third, also with the Sweetwater. An extra prize was awarded to Mr. Osman for a good sample of Foster's Seedling.

Peaches were best shown by Mr. Lees, gardener to Mrs. Marsland, The Wilderness, who had a grand dish of Téton de Venus, large and beautifully finished, a fine, richly flavoured Peach not often exhibited. Mr. Pound, gardener to G. May, Esq., Caversham, and Mr. Cox, gardener to J. H. Blagrove, Esq., Calcott Park, were second and third with Princess of Wales, nearly equal in point of size, but Mr. Pound's fruit the cleaner. There were six other dishes. There were twelve dishes of Nectarines, none noteworthy in point of size, but all admirably ripened and coloured. Mr. Pound was first with a splendid dish of Pine Apple, in the highest degree creditable to him, Messrs. Cox and Ashby being second and third with Victoria, both capital. There was only one dish of Apricots—Moor Park—shown by Mr. Maher, and the second prize was awarded. Of Figs there were three lots, Mr. Ashby being first with a good dish of White Ischia, fully ripe, and Messrs. Booker, gardener to W. B. Monck, Esq., Coley Park, and Mayne, gardener to Lord Saye and Sele, Reading, second and third. There were no less than fifteen exhibits of Plums, three dishes of each—a splendid display. Mr. Cox was first with Washington, Pond's Seedling, and Kirke's Purple, Mr. Turton second with Bodaert's Green Gage, Washington, and Pond's Seedling, and Mr. Waite third.

Kitchen Apples were shown largely and well, dessert varieties not quite up to the same standard. There were four lots of the latter, six dishes of each, Mr. Paxton, gardener to the Hon. C. S. Irby, winning with an excellent collection, the varieties being Peach, Worcester Pearmain (poor), Blenheim Orange, Duchess of Oldenburg (a splendid dish), Strawberry Pippin, and one incorrectly named. Mr. R. Webb, Beenham, was a creditable second, and Mr. Hinton, gardener to J. Leslie, Esq., Reading, third. There were seven exhibits of culinary varieties, and here Mr. Webb was placed first with a capital collection, the varieties being Warner's King, Cox's Pomona, Stirling Castle, Gravenstein, Wellington, and Ecklinville Seedling. Mr. Cox was a very good second, and Mr. House, gardener to J. O. Taylor, Esq., Reading, third. Pears (dessert) were admirably shown by Mr. Goodman, gardener to C. Hammersley, Esq., Bourne End, who was a good first, Messrs. Paxton and House following. With stewing varieties Mr. Paxton won, Messrs. Goodman and Read following.

Of Melons there were six brace. Mr. Dockerill, gardener to G. W. Palmer, Esq., Reading, won with beautiful fruits of Hero of Lockinge, deliciously flavoured; Mr. Bowerman second with the same variety; and Mr. Lockie, gardener to the Hon. G. Fitzgerald, Windsor, third with a variety named Imperial, scarlet fleshed. Cucumbers were well shown by Mr. Lockie, who was first with a very neat brace of his variety Perfection; by Mr. Booker, who was second with Phippen's Improved Telegraph; and by Mr. Kneller, gardener to W. S. Portal,

Esq., Malsbanger Park, who was third with Model. Mr. Phippen offered prizes for his variety of Telegraph, and some good fruits were shown.

Collections of fruit formed an admirable display. Mr. Ashby was first with eight dishes, a most praiseworthy exhibit, comprising Black Hamburgh and Muscat of Alexandria Grapes, Sutton's Masterpiece Melon, Prince of Wales Plums, Royal George Peaches, Elruge Nectarines, White Ischia Figs, and Morello Cherries. Mr. Goodman was second; he had splendid Black Alicante Grapes, and fine dishes of Dagmar Peaches and Williams' Bon Chrétien Pears amongst others. Mr. Aitken, gardener to Major Meeking, Slough, was third; and there was one other exhibit. Mr. Cakebread won with six dishes, his collection consisting of Black Alicante and Muscat of Alexandria Grapes (both excellent), Morello Cherries, Queen Pine, Hero of Lockinge Melon, and Washington Plums; an excellent display. Mr. Osman was a good second with capital Grapes, and Mr. Paxton third. Of miscellaneous fruits the best collection was that of Mr. Goodman.

Messrs. T. Rivers & Son had an extensive and excellent display of fruit, both gathered and on trees in pots, which evoked much interest. It was not in competition.

PLANTS AND GROUPS.

Specimen stove and greenhouse plants were not quite up to the standard of former years, and it is evident that huge trained plants are losing popularity, not by any means too soon. Allied, however, with some admirable groups and smaller decorative plants they produced an imposing effect. Mr. Aitken won with nine specimens—healthy, well-flowered plants of *Clerodendron Balfourianum*, *Rondeletia speciosa* major, *Allamanda grandiflora*, *Eucharis amazonica*, *Lagerstroemia indica*, *Bougainvillea glabra*, *Dipladenia insignis*, *Ixora Williamsi*, and *Allamanda Hendersoni*. Mr. Mould, Pewsey, was second with *Statice Butcheri* and *Erica Uhriana* superba, in very fine condition; Mr. Wills, gardener to Mrs. Pearce, Southampton, was third. Variegated and handsome foliage plants were not so good; indeed, they scarcely call for comment. Mr. Wills had some clean, well-grown plants, and was placed first. Stove and greenhouse Ferns were staged in capital condition by Mr. Aitken, all being fresh, clean, and healthy; and Messrs. Dockerill and Wills, who were second and third, also had plants which did them credit. Mr. Butcher, gardener to G. Palmer, Esq., Reading, won with a single specimen, a good plant of *Eucharis amazonica*, well furnished with its beautiful flowers. Mr. Bright, gardener to P. Harslake, Esq., was second with *Fuchsia Charming*. For a specimen new or rare plant Mr. Wills won with the variegated leaved *Phrynium variegatum*. Mr. Lane won with table plants, Mr. Aitken following, and Mr. Dockerill with *Lycopodiums*.

The groups were in every respect admirable. The first prize was awarded to Mr. Woolford, gardener to A. Palmer, Esq., Reading, for a beautiful arrangement, light, graceful, and free, which showed the improvement that has been effected in plant arrangement of late years. A smaller group from Mr. Aitken was placed second, and that from Mr. Wills third. There was a doubt as to the latter two, but none whatever as to the first.

Achimenes, *Fuchsias*, *Balsams*, *Cockscombs*, *Liliums*, *Coleuses*, flowering and variegated *Pelargoniums*, with *Palms* and *Begonias*, added to the display. Messrs. Dockerill, Bright, Aitken, Woolford, Balchin, Booker, Lockie, Ashby, Castle, Mayne, and Midwinter were amongst the chief prizewinners. A first-class certificate was awarded to a new *Coleus* exhibited by Mr. Phippen, and named *Duchess of Fife*, for its dwarf compact habit.

CUT FLOWERS.

These were extensively shown. Mr. Walker, Thame, won with eighteen *Dahlias*, and also with twelve varieties, Messrs. Cheal & Sons, Crowley; Mortimer, Farnham; Wheeler, Henley; Shrimpton, Beech Hill; and Woolford also showing them well; and Messrs. Cheal & Son exhibited bunches of single varieties in good condition. *Gladioli* were best shown by Mr. Dockerill. Mr. Walker had a charming stand of quilled *Asters*, and also won with French varieties, all beautiful blooms. Mr. Midwinter also showed *Asters* remarkably well. Double *Zinnias* from Mr. Walker were in splendid condition, and easily won him first prize. Mr. Phippen won with eighteen bunches of cut flowers, mostly hardy, and indicating the present great popularity of herbaceous plants. Mr. Such, Maidenhead, was second. With twelve bunches Mr. Castle was a good first. *Phloxes* were best shown by Mr. House. With hutton-hole flowers and bridal bouquets Messrs. Perkins, Coventry, and Phippen were most successful. Messrs. Jeffries & Son, Cirencester won with *Roses*, Messrs. Cheal & Perkins following, Messrs. Perkins showing Mrs. John Laing well in another class. A certificate was awarded to Mr. Owen, Maidenhead, for his excellent strain of *Begonias*. Messrs. Such, Maidenhead, and Oakshott & Millard, Reading, showed cut flowers and plants in pots. The local classes were well filled and helped to swell the display.

VEGETABLES.

These are usually a great feature at Reading, several of the large seed firms offering sufficiently handsome prizes to secure the entry of some of the best vegetable growers in the south of England. This year the display was as good and extensive as on any previous occasion. There were some marvellous examples of the new *Onion Ailsa Craig*, referred to on page 179 of last week's *Journal*, *Potatoes* and *Cauliflowers* being also very fine. The exhibits in the special classes are referred to in the order we found them on the stands. Mr. Pope, gardener to the Earl of Carnarvon, Highclere, was first with a collection in the com-

petition for Messrs. Oakshott & Millard's prizes. He had some grand specimens of *Ailsa Craig Onion*, capital *Potatoes* (*Abundance*) and *Tomatoes* (*Perfection*), also very good *Celery*. Mr. Lye, gardener to W. H. Kingsmill, Esq., was second; Mr. Goodman third; and Mr. Harris, High Wycombe, fourth. For nine kinds of *Potatoes*, also Oakshott & Millard's prizes, Mr. Lye won, showing *Reading Perfection*, *Chancellor*, *The Magistrate*, and *Satisfaction* well amongst others; Mr. Pope was second; and Mr. Springbett, Sulham, third. Messrs. Carter and Co., High Holborn, also offered prizes for a collection. Mr. Lye was first, *Holborn Model Leek* and *Early Autumn Giant Cauliflower* being excellent; Mr. Harris was a very good second; and Mr. Waite third. All these were fine lots. Mr. Kneller, gardener to W. S. Portal, Esq., Malsbanger Park, won Messrs. Webb & Sons' chief prize, *Perfection Tomato* being excellent, also *Ailsa Craig Onion*. Mr. Bowerman was a very good second, and Mr. Waite third. Mr. Fidler, Reading, also offered prizes for a collection, and the first fell to Mr. Pope for a capital lot; Mr. Bowerman second; and Mr. Lye third. All these growers had every reason to be proud of their exhibits. Messrs. Sutton, Reading, did not offer prizes for vegetables as in former years, but instead offered premiums to the value of £12 in various other classes, in addition to the Society's prizes. Messrs. R. Beale & Co., New Southgate, were highly commended for their fertilising moss, as being especially adapted for sending plants by post; also for their plant collar, for supporting top-dressings to plants in pots.

SANDY AND DISTRICT.

THE twenty-first annual gathering of this continuously expanding Society was held on Friday last in the beautiful and compact little park of Sandy Place, the situation and surroundings of which are admirably adapted for a successful exhibition, embracing under the spacious head of horticulture such a wide range of objects as is here brought together; for in addition to horticulture pure, farm, market garden, and dairy produce, poultry, pigeons, birds, rabbits, bees, and bread, and this year the Committee successfully introduced a department for dogs. The weather was exceptionally fine and hot, and the hutter in the tent constituted a useful self-registering thermometer, the major portion of the exhibits in that division being reduced to the condition of sardine oil. There was consequently a large concourse of visitors from the neighbourhood, the surrounding counties, and the metropolis; from which special trains were run, but the tents from the intense heat were partially deserted.

Plants in pots were well and largely shown, four collections being staged in the open class for ten stove and greenhouse plants in flower, distinct, and some fine specimens were placed at much disadvantage by being set up on an enormous staging far above the eye, the consequence being that there is no *coup d'œil* in the plant tent at Sandy, a few insignificant objects only meeting the eye and blocking the view of this tent; and only those well accustomed to studying the upper tier of a picture gallery can with any degree of ease inspect and admire plants some 6 feet through towering up with their names at telescopic distance, the space in front for visitors being so contracted that a careful examination becomes painful.

Probably the amount paid for carpentering in the erection of the massive stage would more than provide a wider and more suitable tent, and exhibitors might be saved the heavy and risky business of hoisting up these heavy specimens. In this class Messrs. J. Cypher & Son, Exotic Nurseries, Cheltenham, had a grand specimen of *Phenocoma prolifera* Barnesi, well flowered plants of *Bougainvillea glabra*, *Clerodendron Balfourianum*, *Allamanda Hendersoni* and *nobilis*, *Statice profusa*, and four fine *Ericas*; this collection was placed first; Mr. W. Finch, gardener to J. Marriott, Esq., Coventry, coming second with handsome and regularly matched plants of *Rondeletia speciosa* major, *Ixora Williamsi*, *Fraseri*, *Dipladenia amabilis*, *Miltonia spectabilis*, *Clerodendron*, and three *Ericas*. Mr. G. Redman, gardener to J. H. Goodgames, Esq., Eynesbury, Hunts, was third; and Mr. J. F. Mould, Nurseries, Pewsey, Wilts, was fourth. Mr. Rabbitt, gardener to General Pearson, The Hazels, Sandy, took first for twelve well flowered specimens of *Zonal Pelargoniums* in the open class, the varieties being of well known sorts; Mr. Redman gaining second place. For six grand and well grown *Fuchsias* Mr. G. Claydon, Woodbury Hall Gardens, was deservedly awarded first, also for six stove and greenhouse Ferns and six foliage plants.

Cut Flowers.—For forty-eight cut *Roses* (not less than twenty-four distinct varieties) open to all, stands of fairly good size, substance, and colour for the season were set up by Messrs. Paul & Son, The Old Nurseries, Cheshunt, Messrs. G. & H. Burch, Rose Growers, Peterborough, and Messrs. Laxton Bros., Nurseries, Bedford, their exhibits being recognised in the order placed. In Messrs. Paul's first prize stand were good flowers of *Souvenir d'Elise*, *Perle des Jardins*, Mrs. Jowitt, Mrs. Baker, and *Maréchal Neil*, Messrs. Laxton's best blooms being *Ella Gordon*, *Harrison Weir*, *Madame S. Rodocanachi*, and *Alfred Colomb*; in Messrs. Burch's lot Mrs. John Laing, *Duchess of Bedford*, *Chas. Darwin*, and *Anna Olivier* were noticeable, but the intense heat of the tent made sad havoc with the flowers in the latter part of the afternoon. For twenty-four *Roses* (not less than twelve distinct varieties) open to amateurs, Mr. E. B. Lindsell of Bearton, Hitchin, was first, his stand containing fair blooms of *Chas. Lefehvre*, *Baroness Rothschild*, *Comtesse Nadaillac*, *Rubens*, and *Anna Olivier*. Mr. Lindsell was also awarded first for a stand of six *Gladioli* in the same division. For twenty-four spikes of *Gladioli* in the open class Messrs. J. Burrell & Co., Howe House Nurseries, Cambridge, showed the only and a truly magnificent stand, and were awarded first honours. Their stand included *Iolanthe*,

first-class certificate Royal Aquarium, rich orange rose, flushed deeper, a striking large seedling of their own raising; Baroness Burdett Coutts, pale rosy lilac; Grande Rouge, brilliant scarlet, fine spike; Africaine, good dark brownish red; Ovide, Rupert, A. Brongniart, Flamingo, Enchantress, Conquerant, Rayon d'Or, Pyramide, Ondine, Mikado, Atlas, Florence, and several promising seedlings as yet unnamed.

For twenty-four Dahlias in the open class Messrs. Heath & Son of Cheltenham were placed first with large but somewhat coarse flowers. Their stand, containing notable blooms of W. H. Williams, Thos. Hobbs, Jas. Keith, Mrs. Gladstone, Miss Cannell, Mrs. W. Stark, and Wm. Rawlings. Mr. H. Glasscock, the Bishops Stortford veteran, gaining second with refined but smaller flowers, amongst which were prominent Glowworm (Turner) new 1888, very fine bright scarlet and a decided advance in its class, Mrs. Theobald, Burgundy, Mrs. Harris, and Mrs. D. Sanders. For twelve Dahlias Mr. W. H. Apthorp, Cambridge, was first and Mr. G. Arnold, Leighton Buzzard, second, and for six Fancies Mr. Glasscock was first and Mr. Apthorp second. Asters, Zinnias, and French and African Marigolds were largely represented, the latter especially fine, the chief prizewinners in these classes being Dr. Swaine, Arlsey, Mr. Rabbitt, Mr. H. E. Fuller, and Mr. W. Bourne, Cambridge. Mr. Bourne was also awarded first for a fine stand of hardy cut flowers. Messrs. Laxton Bros., Bedford, also showed a large and showy collection of hardy flowers not for competition.

Fruit.—This was not equal to the displays of former years, some of the principal exhibitors being absent. For a collection of eight varieties Mr. R. Carter, gardener to Col. Duncombe, Waresley Park, was the only and successful exhibitor, showing a very creditable collection. For two bunches black Grapes (Hamburgs excluded) Mr. R. Kitehen, Thorney, Cambs, was first with well-finished Gros Maroc; and Mr. H. Ridgwell, Cambridge, second. For two bunches of Black Hamburgs Mr. C. Moore, St. Neots, was first; and Mr. J. A. Baker, St. Ives, second. For white Grapes the chief prizewinners were Mr. G. White (for Muscats), Mr. R. Carter, and Mr. C. Forbes, Trumpington, Cambs. Pears, Apples, and Plums were largely shown, but mostly underripe, and inferior in colour and size.

Vegetables.—These are always a feature at Sandy, were shown well and largely in all the divisions. Potatoes were perhaps rougher and somewhat more undersized than are usually found here. For a basket of twelve varieties of vegetables in the chief amateurs' class Mr. F. Faint, gardener to R. Hoare, Esq., Maiden Hill, Hertford, was first; Mr. G. Vyne, gardener to C. Franklin, Esq., Bedford, second; and Mr. H. Ridgwell, third. For Red Tomatoes Mr. J. Witney, Turvey, Beds, was first with sound medium-sized even fruits of Model; and for Yellow Tomatoes Mr. J. A. Baker was first. Some fine dishes of Perfection Red were passed by the Judges as being past perfection. For a collection of six varieties of Potatoes in the same division Mr. Faint was first with very clean and even specimens of Satisfaction, Abundance, Snowdrop, Schoolmaster, International, and Beauty of Hebron; and Mr. W. Tildesley, Bedford, second. The best Potatoes in the Show were a dish of Satisfaction from Mr. Jas. Simkins, Shillington, Beds, and which obtained the first prize in the chief amateurs' class for twelve white kidneys; the tubers were remarkably handsome, and averaged 2 lbs. each in weight. Mr. Simkins also obtained the first prize for a dozen Globe Spanish Onions, very perfect specimens. Mr. Dale, gardener to J. N. Foster, Esq., Sandy Place, was awarded first also for twelve fine White Spanish Onions of the Sandy Prize type. Many other good collections of vegetables were shown, but the exhibits at Sandy are too numerous and extensive to compass in one day, and it is a matter of regret that so educating a collection should have to be dispersed, half seen and half appreciated, at the end of a few hours only.

HARPENDEN.

THE eleventh annual Exhibition was held in Wrothamsted Park on Wednesday, August 28th. in most brilliant weather. This told well in favour of the Society after having such a disastrous day last year. It is to be hoped it will now be able to hold its own, though I fear the balance is still on the wrong side.

Taking the plants first, Mr. Turk, gardener to Mr. Bosanquet, Ponfield, Little Berkhamsted, was first; Mr. T. Notting, gardener to Mr. Maple, second; and Mr. Pepper, Tenin Water, third. For six foliage plants Mr. Metting was first, Mr. Turk second, Mr. Sconce, gardener to Mr. Hil, Kankwick, St. Albans, third. For forty-eight Roses Messrs. Paul and Son were first, for twelve the same firm was also to the front. They were first for twenty-four Dahlias, and Mr. Littlechild, St. Albans, was a good second. For twelve bunches of herbaeous plants there was a good competition; Mr. J. Hershaw was first, Dr. Maelcan second, and Mr. Turk third, all showing well. For a similar number of stove and greenhouse cut flowers Mr. Anning, gardener to Mr. Brown, Diswell, was well to the front, many of his blooms being of choice Orchids; Mr. Turk was second.

For the best group of plants Mr. Nutting was first, Mr. Turk second. There were other two groups, and contained some well cultivated plants, but the taste in arranging was far behind that of Mr. Nutting, to say nothing of the beautiful specimens put up by him. For table plants Mr. Nutting was again first, Mr. Anning second. For six exotic Ferns Mr. Sconce was a long way ahead with a superb half-dozen, Mr. Nutting second.

For black Grapes Mr. Faint, gardener to Mr. Hoare, Hertford, was first, the same exhibitor coming first for a grand collection of vegetables and a most clean and handsome collection of Potatoes. Among the other successful exhibitors was Mr. Hogg, The Hyde, Luton; Mr. Sibley, Harpenden; Mr. Pepper, Mr. Tilbury.—G. M. H.

FRUIT FORCING.

VINES.—*Early Forced Vines in Pots.*—Those for starting in November must not be allowed to become dust dry at the roots. They will now be at rest, the wood ripe, the laterals cut close in, and the canes shortened to about 6 feet, according to the situation of the plump eyes. Whilst the cuts are dry dress them with styptic or knotting to prevent trouble from bleeding. They should be kept in a cool airy house.

Earliest Forced House.—Early forced Vines, when care has been taken to preserve the principal foliage by cleanly culture and a judicious encouragement of the laterals after the fruit was cut or ripe to prevent premature ripening of the leaves, will be in a condition to be cut ordinarily; but with early forced Vines it is not necessary to wait until all the leaves have fallen before pruning, as the Vines will be sufficiently matured, the wood being brown and hard, and the leaves, or some of them, turning yellow. The pruning will cause the Vines to go more quickly and thoroughly to rest. If in good condition they will afford bunches quite large enough when pruned to a couple of buds from the base, but if the Vines are weak from overcropping or a long course of forcing the spur shoots may be left a little longer, to secure larger bunches. When this method is adopted shoots should be taken from as near the base as possible in the spring, and not be allowed to carry fruit, but be stopped at about the sixth leaf, and the laterals at the first leaf, and subsequently as produced. Such shoots are sure to form good buds; the extra foliage will tend to invigorate and support the fruit on the other shoot, which can be cut away in due time in favour of that retained for fruiting the following season. This alternate system of fruiting necessitates the shoots being kept wider apart for development and exposure to light and air. If the Vines are grown on the extension system it will only be necessary to cut back to plump buds on firm ripe wood, being guided by the space at command, for there must not be overcrowding. It is important that the house be thoroughly cleaned, and the Vines also. Any weakly Vines, or those in an unsatisfactory state, may be improved by removing the soil down to the roots, and substituting fresh loam, with an admixture of crushed bones, to the extent of about a twentieth, and if calcareous matter be wanting add a sixth to a tenth of old mortar rubbish, according to the character of the soil, more being required for heavy than for light soil. Lift any roots available for the purpose, laying them out upon the fresh compost, and cover 3 or 4 inches deep. This is best done before the fall of the leaf. It is a mistake to allow Vines when at rest to become dry at the roots. Comparative dryness is desirable, yet great injury is caused by allowing the soil to become dust dry. The outside border should have a covering of some kind to protect the roots from the heavy autumn rains, which reduce the temperature considerably. Glass lights are preferable, as they throw off heavy rains, whilst allowing the sun to penetrate the soil. Many, however, are obliged to rest content with a covering of leaves and litter after cold weather sets in.

Young Vines.—Those that have made a strong growth and are late in ripening should be assisted with fire heat, maintaining a minimum of 65°, and maximum of 75° from fire heat, continuing it until the wood is ripe, accompanied with free top and front ventilation. Discourage any further growth by the removal of the laterals as they appear, and withhold water from the roots, only the soil must not be allowed to become dry, and, if the roots have the run of outside borders, some spare lights placed over the border so as to throw off heavy rains will be very beneficial.

Late Grapes.—Grapes for some unaccountable reason are ripening early. Gros Colman, for a wonder, is colouring very little behind Black Hamburgs, and its footstalks are more woody than usual. There is nothing like an early start with late Grapes—they require plenty of time. Keep the laterals well thinned, and thereby admit as much air as possible to insure the finishing of the crop, not by large reductions of foliage at a time, but by frequent pinchings. Maintain a night temperature of 70° to 75°, falling 5° to 10° during the night, increasing to 80° or 85° by day, accompanied with a circulation of air constantly, and free under favourable atmospheric conditions. It will require sharp firing to finish those that are only commencing colouring before the days are too short to admit of full ventilation; indeed, more may be done in the next month or six weeks than in twice the time later on. Those Grapes well advanced in colouring and ripening may have the atmospheric moisture reduced; those only colouring should have a moderate amount of moisture to assist their swelling, not neglecting to apply water to the inside border as may be necessary.

MELONS.—The latest plants are fast covering the trellis and showing blossoms. If the crop is wanted quickly the early flowers should be fertilised. A portion of the plants may have the first fruits removed, and they will afford a later and fuller crop from the second laterals. Earth up the plants after the fruit is set, not before, and after that be sparing with the syringe, employing it only during bright afternoons and then early, taking care not to overwater at the roots, yet maintaining a genial moisture in the atmosphere by sprinkling. Promote

also healthy root action by proper moisture in the soil. Plants in frames have suffered seriously, and in some instances irreparable injury from the prolonged cold and wet of the past few weeks. Melons grown under such disadvantageous circumstances are poor in flavour, indeed they are not of any value. Where, however, linings have been duly attended to, so as to promote a genial warmth in the frames and allow of a little air being admitted to provoke evaporation, the plants are healthy and promise to ripen satisfactorily. The plants will only require water occasionally—a damping early on bright afternoons, and should only have moisture in the soil to keep the foliage fresh. Let the fruit be elevated above it on inverted flower pots, applying good linings to maintain the requisite heat, a warm, dry, and well ventilated atmosphere being essential to the well ripening of the crop.

CUCUMBERS.—The shorter days and longer colder nights necessitate the earlier closing of the house, and the employment of the syringe also earlier, so as to have the foliage fairly dry by dusk. Fire heat will also be necessary to maintain a temperature of 70° to 75° by artificial means, falling about 5° during the night. Afford every encouragement to the autumn fruits, removing the first blossoms of a pistillate kind, as also the male blossoms and tendrils. Shading will not be necessary now, and avoid syringing as far as possible, damping being usually sufficient on all but bright days, when light syringing early in the afternoon will be beneficial.

Keep plants in frames rather thin of foliage, have linings as necessary to maintain a steady progressive growth, care being taken not to overwater. As the nights are cold afford a covering of mats over the lights. Ventilate early, closing early in the afternoon, so as to husband the sun's heat, which will do much to maintain the requisite night temperature—viz., 65° to 70°. Sow from now to the middle of the month for a supply of fruit at Christmas and the New Year onwards. Telegraph is good for this, indeed for any sowing, while Cardiff Castle is free and excellent for everyday use.

KITCHEN GARDEN.

RADISHES FOR WINTER AND SPRING.—Salad plants are never too abundant in winter, especially after severe weather, except with those who have proper means of keeping Lettuces and Endive. Radishes are often the only salad existing in the spring months. They may be secured without the aid of artificial means, as they are as hardy as Turnips, and do not deteriorate in severe weather. It is therefore important that all who desire to have something in the form of salad in winter and spring should grow Radishes, and they are especially valuable for amateurs. The China Rose and the Black Spanish are the only varieties we recommend for winter, as they are the only ones we have succeeded in keeping good from November until April. The seed of these must not be sown too soon, as if early they become too large, and by midwinter they will have a vacancy in the centre of the roots. From the beginning to the middle of September is the best time to sow, not in rich soil, as a firm moderate growth is the best to resist the frost. Do not dig land before sowing them, but after clearing away some old crop hoe and rake the surface, and sow in drills 10 inches or 1 foot apart. If they are too crowded when they are a few inches high they should be thinned to 2 inches apart, and keep them free from weeds.

PLANTING SPRING CABBAGES.—Many approve of planting their Cabbage for the spring at two or three different times, and it is a good plan, as if some should chance to be too early the next may be better. We plant at three different times—early in September, the middle of that month, and at the end of it. The system of planting two or three times is also advantageous to the young plants, as in all seed beds some are forward while others are not half ready, and the later plants gain size and substance they would never attain if left in a crowd. Wherever the plants are ready let some be placed out at once. They must have a good position. Our favourite position for planting is after Onions, as these invariably have a good piece of the garden. If the ground is rich now give it a moderate dressing of lime, and fork this in a few days previous to planting. If the soil is poor give it a dressing of manure, which may either be dug or forked in. We do not always approve of the plan of merely levelling and clearing the surface and planting the Cabbages without stirring the soil, as in this case we have often noticed that the plants do not all grow alike, some taking the lead of others; but when the soil is forked over they grow equally. Drills about 3 inches deep should be opened with a drag hoe and the plants dibbled into these. If a small sort keep them 15 inches apart each way, if large give them 18 inches.

LATE PEA PESTS.—We have had to net all our rows of late Peas. The sparrows, of which there are a great many this season, open the pods and remove the Peas as soon as the latter are well formed. A reader explained to us the other day that he had tried everything to frighten them off and failed, and our reply was that he would never succeed until he covered the Peas with nets. This is our only remedy, and as some of the nets that protected the fruit are now disengaged they may be profitably employed covering the late Peas.

THINNING WINTER CROPS.—Spinach, Turnips, and other winter crops are now growing freely, and much of their success in winter depends on their being well thinned. Some keep them very close under the impression that by having a large number they will gain by them; but it is only by admitting plenty of light, air, and sun to late crops that they can be relied on in severe weather, and bulbs or plants that are grown well exposed in autumn invariably prove the most profitable and satisfactory in winter. It is a mistake to let them become very

crowded and then give them a severe thinning on one day, as the full advantages of thinning can only be secured in the case of all crops, more particularly winter ones, by beginning to thin early and never allowing the plants to be crowded at any time.

LETTUCES AND ENDIVE FOR WINTER.—Plants secured from seed sown early in August are now ready for placing out. These will come into use about the end of October and remain good as long as they are kept from frost. Some of them may have to be lifted by-and-by and placed in frames, but in the meantime the whole of them should be planted in the open quarters. Our favourite place for all such at this time is a south, east, or elevated sunny border, as there they grow freely and are generally protected for a considerable time after plants in more exposed positions are suffering. The soil should be forked over previous to planting and the plants may be dibbled in at a distance of 10 inches each way, but if some of them can be shifted into sheltered positions in October they may be planted as close again as this in the rows, and when moved lift every other plant, when those remaining will have plenty of space.

LATE GREENS.—We never approve of vacant quarters in the kitchen garden. The other day a gentleman remarked, "You do not keep much in fallow." Our reply was, "No, it does not pay." There is no use in planting Brussels Sprouts at or after this time, as they would never gain size. Savoys may form small heads, but the Kales will attain a useful size, and so will Leeks, and vacant spots may be filled with these two crops. Continue to earth up Celery and early Leeks, keep weeds down by frequent hoeing, remove all decayed vegetables and leaves, and if any crops are behind give them a stimulant by shaking a little guano round them if the weather is wet, or liquid manure from the same material if dry.

AT THE MOORS.

CAUSES OF SWARMING.

WITH one exception every hive that swarmed was owing to the queen becoming exhausted, which neither supering nor nadir-ing would have prevented. Several were, or ought to have been, young queens of last year, being imported ones, and as true crosses as could possibly be, so much so that I could not tell to what race they belonged. The cause of this being inexplicable I made some inquiry, and was informed that an English dealer had been instrumental in procuring colonies of bees of a different race set in the neighbourhood of a breeder, in order to destroy his trade and reputation, which if true does not redound to his credit, and I hope some other explanation will be forthcoming. The excepted hive that swarmed was owing to an after swarm issuing from another on a windy day, when a part of the bees and queen were blown towards and on to it, when a large swarm issued. I returned all the swarms, having lost one only, and formed a nucleus in an empty hive I sent for on seeing the state of matters. Should the weather clear up these young queens will enable me to supply several persons who have been asking for them, as I have all queens for next season at home.

CAN BEES COUNT.

My bees stand at the foot of one glen and on the point of intersection to the main one that leads to many others, and behind a stone dyke which runs east and west, the hives facing north. The hive I had forwarded to me was placed at the west end of three detached hives, as it is bad policy to crowd the hives. The empty hive was placed 6 feet from the western one, the bees and drones of which alike immediately entered, while some of the bees from the next hive entered the westmost one. I then moved it to 20 feet distant, and this time with the entrance quarter round, and still some bees and drones flew towards it. The lesson is the same as that I have so often taught, Never alter the appearance or aspect of hives after September.

DO BEES FLY IN A STRAIGHT LINE.

It is generally believed that bees when returning to their hives fly in a direct line, but this is not verified here. The bee stands were at the foot of a glen that separates two hills. In order to reach another glen situated at a right angle on the hill at a

considerable elevation rather less than a quarter of a mile distant, where the Heather is extra fine, and where gold was at one time plentiful and is sometimes wrought for yet, in a straight line the bees would have come down the hill at an angle, but instead they flew right down the second named glen until they reached the bottom, then turned to the east at a right angle again, flew down the main glen, and past their hives from 150 to 200 yards where the valley and dyke nearly intersect, then over the dyke, reaching their hives on the lee side of it, flying at least a mile further when windy than when calm.

DIFFERENT RACES OF BEES.

The only regret I have is that those who have lifted their voices against the foreign races of bees were not here to judge for themselves of their superiority. I have read of a colony in America gathering 30 lbs. in a day, which the owner thinks will be able to record 40 lbs. when his hives are in order along with the pasturage. I had a colony of Syrians that gathered 60 lbs. in three days, but 33 lbs. is the highest I ever heard of in this country, and yet my queens never filled "twenty four standard frames" with brood in twenty days. I think one-half of the above is not bad work, which I consider would be the extreme of the breeding powers of my queens this year, and a great deal more than "ten standard frames" would contain. The amount gathered by my bees is treble that any ten-standard frame hive could possibly do. But more of this again.

THE PUNIC BEE.

In compliance with the request of "A Hallamshire Bee-keeper" I took one of these queens to the Heather, but singular to say it has done the least of any hive I had, but must add one trial is insufficient to decide the merits of any race, and it may be the good qualities of this race that has precluded it from reaching the proportionable weight of others; but it is now well forward with young bees, and may at the end surpass others. If the chance of competition fails owing to unsettled weather the good quality of the Punic bee must remain an untried one for another year. Be that as it may, I will give them every chance, but am sure it will be difficult to get a race of bees to surpass the eastern ones. As my convenience for scribbling is not the best I will defer other experiences till another time.—A LANARKSHIRE BEE-KEEPER.

All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Carnations Dying (F. L.).—The plants sent appear to have been very weak to begin with—too weak, and hence unable to resist the attacks of a fungus which causes the destruction of so many that are in a debilitated state.

Plants Unhealthy (C. N.).—If the house is suitable in other respects and a genial atmosphere maintained, or in other words, if you have been able to grow similar plants in other structures, you may, we think, conclude the glass is unsuitable, and we should not think of employing the kind you describe. We have seen many failures arise by

the use of very thick rough glass, and we consider it unsuitable for hothouses generally.

Stirling Castle Apple (H. J. H.).—It is not an acid Apple, but an excellent early culinary fruit, with white flesh, very tender, juicy, with an agreeable and pleasant flavour, not in any respect similar to Dumelow's Seedling or Wellington. It is in use in August and September, the tree being a great bearer, and more suitable for dwarf than large culture. Perhaps the specimens were unusually fine from being grown against a wall.

Defective Valve Arrangement (B.).—We have several times stated that for having the heat under control valves must be placed on return as well as on flow pipes under the circumstances you describe. You had better make the necessary provision at once, or cease firing briskly and continuously, or an accident may occur. The more water is heated the more it expands, and it traverses most freely where it meets with the least resistance, and this it appears in your case is along the return pipes.

Stopping Mignonette (W. S. S.).—It takes about a month to six weeks from pinching off the flower spikes until the plants make fresh growths and are furnished with fresh spikes, but much depends upon the condition of the plants at the time of stopping. If they are not very woody when pinched young growths will be produced more quickly than when the wood is hard and stunted; in the latter case it will take six to eight weeks, the plants never being satisfactory when allowed to become exhausted before resorting to pinching.

The "Best" Manures (A. S.).—No one can say what is the "best" manure for a particular soil without knowing the constituents of that soil. If you describe the nature of the soil to which you refer, and especially the herbage, assuming turf is taken from a pasture, we shall be in a better position to advise than by giving a categorical reply to your question in the absence of any data whatever on which to form an opinion worth giving. The quantity of manure to use is also most important, and you do not indicate your proposals in that respect.

Vine Leaf Mottled (A. B.).—There is nothing the matter with the Vine leaf. On the contrary, it is a good leaf, and if all the others are like it the Vine cannot be in a very bad state. The colouring is natural to the variety when the leaves change and assume their autumnal tints. The soil in which you grow Tomatoes will be improved by an admixture of lime shortly before planting, though water from a drain may contain small vibrios which are injurious to the roots of many plants, causing them to have a warty appearance. The crushed flower sent is probably a Nerine.

Injured Vine Leaves (F. J.).—We do most readily admit there is "something wrong" with the leaves sent, but only in one respect can the wrong be righted now, and that is clearing off the red spider with which they are infested. If there is only one young Vine in this state, you had better sponge the leaves carefully yet thoroughly with Gishurst compound, nicotine soap, or even softsoap and tobacco water. This must be done on both sides, for on both we find insects plentifully. This will not materially improve such leaves as you send, as they are beyond restoration, but as you observe others are not so bad, by all means cleanse the whole of them at once. The Vine may then be to some extent benefited, and it will be a decided advantage to destroy the attacking pest. The leaves are also scorched and wanted, mainly through errors in ventilation and general management.

Fungus on Plum Trees (H. B.).—We are of opinion that the condition of the leaves sent is mainly the result of aphides, the filth attending which is almost invariably taken possession of by the black fungus. We have seen many instances of this, not with Plums alone but various kinds of trees and plants. If you can prevent insects, attacking the trees, no matter by what means, and also maintain healthy root action in good soil, we do not think the fungus will attack the trees. This is not the "red rust," which is more difficult to combat and overcome. When trees lose their leaves soon after midsummer they cannot be expected to store material for the production of fruit. We have seen many trees rendered black with fungus this year, the certain result of a previous and serious attack of aphides. The leaves you have sent have always arrived dead and dried; if you send more we should much prefer their reaching us fresher in a box with a little green grass.

Neglected Fruit Trees (Northumberland).—1, The procedure pursued with the wall trees is the correct one, and we can only further suggest that root-pruning be resorted to early in autumn, forming out a trench about one-third the distance from the stem the trees cover in extent of wall space, and as deeply as the roots, which should be detached, the trench being left open for a week or ten days, when it may be filled in, firming the soil well. This may be done early in October. It tends to ripen the wood and buds, and induce shorter jointed and more fruitful wood. If the cutting of the roots be done in a dry time it is possible the leaves may become limp, which will not do any harm, but the soil must not be allowed to become so dry as to cause severe flagging, water being applied to the part undisturbed to prevent the foliage flagging and its premature falling. 2, There ought not to be any suckers at the base of fruit trees. Remove them at once, and in future whenever they appear. The trees are in much too vigorous growth for the formation of fruit buds, for which the heavy manuring is accountable. This, with the looseness of surface, is sufficient cause of their not fruiting. Sowing with Turnips to be dug in in autumn is a novel way of seeking fertility. It would be much better to give a dressing of clay marl,

spreading it evenly on the surface, a hundred earloads per acre not being too much, and after frost it may be pointed in. The ground will not require any manure again until the trees are fruitful. Keeping the soil loose about fruit trees where it is already light is most injurious. A little thinning of the heads where too much crowded with wood would be advantageous, but we do not advise root-pruning or severe manipulation of the heads. If you cannot obtain the clay marl apply a dressing of lime at the rate of 200 bushels per acre, and in early autumn, not burying it deeply.

Gardenias and Eucharises (S. T.).—So much depends on the condition of the Gardenias, and especially the state of the roots, that it is not easy to say whether your plants should be repotted or not. Assuming, however, that they will receive careful attention in watering, they may be safely transferred to pots just large enough to enable the fingers of the workman to pass freely round the balls of soil when in the fresh pots. A larger shift must be avoided. The soil, two-thirds turfy loam and one-third peat, with a little sand, must be pressed quite as firmly round the roots as the soil is in the present pots; and both that soil and the soil to be used must be in a pleasantly moist state, neither very wet on the one hand or dry on the other. The growths must not be shortened. Let water be applied with judgment and the plants be syringed twice a day in bright weather. A shelf near the glass in a stove will be a suitable position for them, as they need sun to harden the growth; yet a little shade must be afforded if needed to prevent flagging or scorching. In October they may be placed in the Cucumber house, and if they have been well managed they will flower in the winter. If there is any fear of mistakes being made in watering after potting, it would be safer to let the plants remain in their present pots plunged in others to prevent the roots drying. Assuming your Eucharises are strong and the pots filled with roots, keep them in the stove and well watered until the beginning of September, then remove them to a drier house, such as a vinery, reducing the supply of water—in fact, only giving sufficient to keep the foliage fresh. After five or six weeks of healthy rest place them in the Cucumber house or where they can have a night temperature of 65°, keeping the roots decidedly moist, and flowers will be produced in winter, always provided the plants are strong enough for flowering, and healthy. Bottom heat will be of assistance in promoting them flowering after the resting period.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (H.).—1, *Dipladenia amabilis*; 2, *Dendrobium chrysanthum*. (Pelargonium).—1, *Solidago canadensis*; 2, we do not recognise; 3, *Lycasteria formosa*. (E. M.).—*Polygonum cuspidatum*. (T. L.).—We are unable to recognise your friend's plant by a single leaf. If flowers appear and you send us a specimen we shall be glad to help you. (H. M.).—*Lycium europæum*. (J. J. S.).—*Hibiscus syriacus flore-pleno*. (F. P.).—1, *Ceanothus floribundus*; 2, flowers quite withered, but the plant is a *Cistus*; 3, apparently a small frond of *Asplenium viviparum*; 4, *Selaginella Willdenovi*.

TRADE CATALOGUES RECEIVED.

William Bull, 536, King's Road, Chelsea, London, S.W.—*Catalogue of Tuberous Plants and Bulbs*.

Smail & Co., 23, Lime Street, and 99, Queen Street, Cheapside.—*List of Dutch and other Flower Roots*.

Friedrich Adolf Haage, jun., Erfurt.—*Catalogue of Cacti and Miscellaneous Plants*.

Buckland and Broadbent, Gec Cross, near Manchester.—*Select List of Carnations and Picotees*.

Robert Veitch & Son, 54, High Street, Exeter.—*Catalogue of Dutch Bulbs*.

Edmondson Bros., 10, Dame Street, Dublin.—*Autumn Catalogue of Bulbs*.

Charles Turner, Slough.—*Catalogue of Bulbs*.

THE LABOUR ACCOUNT.

THE question, Is profitable farming possible? is still an open one in the opinion of many, and attempts to answer it have been made in a variety of ways, both in writing and practice. Landlords have done their part by a liberal rent reduction, and many of them have tried to show what could be done to improve the general practice. What have tenant farmers done?

They have less expense to meet in rent, they have less to pay for labour, because it is cheaper; but though labour is reduced in cost it is still found sadly out of proportion to returns by the majority of farmers, for the simple reason that they have made no alteration in their system of farming. No one can ever be content to go on farming just to pay one's way and obtain mere subsistence; that is to approximate to standing still to be safe, for under such conditions a single bad season may bring a man face to face with bankruptcy. No; farming to profit is the only safe method, and we cannot rest content with anything short of it, but that is impossible with four-fifths of the land under a four, or rather under a four or five-course shift. What use is it to go on growing full crops of corn if it cannot be done profitably? The markets are open to us, we can easily ascertain the full value of every article of farm produce, and a simple calculation will soon show us in what direction our efforts at improvement may be turned with advantage.

In this matter we can do something more than generalise. It is at this season of the year that our plans for the future are made,

and if we are to make a special effort for reform, first of all let us do our utmost this autumn to clean the land, and turn up roughly for winter all that is not required for winter corn. Then let enough be sown down next spring for four or six years with mixed seeds to enable us to dispense with at least half the horses, and to reduce the labour account by one-half. On a 300-acre farm such a step means an annual saving of at least £300, which may well go for cows, sheep, pigs, or poultry, all most profitable farm stock under good management, all bringing quick returns upon outlay.

Such a new departure will require most careful forethought. The starting a new dairy or enlargement of an old one cannot be done lightly, and every detail must be thought out beforehand. The selection of cows is by no means an easy matter. A first-class cow will give daily sixteen quarts of milk of such high quality as will afford enough cream for 2 lbs. of butter; an inferior animal may barely yield 1 lb. of butter from twelve quarts of milk, so that the higher-priced animal may prove the cheaper by far. The cow-house, too, has much more thought bestowed upon it than it once had. Ventilation and cleanliness now have as much attention in the cowhouse as in the dairy. All this means expense at the outset, which may lead to dairy extension being held over for a while, and preference being given to sheep for the first season or two. This is a mere matter of detail; the chief point is to effect a radical change, which shall reduce labour and render profits possible. No doubt the idea of giving a semi-permanent character to layers will alarm many a man who has been long accustomed to leave his pasture to chance, and to plough-in his layers every year for Wheat. He will talk of foulness and poverty as an inevitable consequence of layers four or six years in duration, and yet he will fold sheep upon his second growth of Clover to enrich the land for a Wheat crop. By a very little stretch of thought he should be able to grasp the possible advantage of folding upon older layers, and eventually breaking up the soil richer in fertility than when it was first laid down.

Once extend this system of one-half or two-thirds of the land in pasture or forage crops to all our great corn farms, and corn growing will assume a new phase, for it will then in a very considerable measure become subservient to the requirements of our live stock, and the general aim will be to feed with home-grown corn, and to avoid heavy cake bills. However tempting the price of imported Oats and Maize may be, it will be worthy of consideration if the superior quality of home-grown corn does not render it most profitable for use. Oats much under a weight of 42 lbs. a bushel are not sufficiently nutritious to be worth buying, and the majority of imported samples are notoriously light. A moderate quantity of home-grown Wheat thoroughly well grown would probably obtain a higher price and better demand than we now have. If, too, ensilage assumes the importance in farm economy which we think it must do eventually, and root cultivation falls into abeyance, there will be a still further reduction in labour and a greater degree of certainty in results, for silage is certainly an operation in farming about which there is no uncertainty, and the saving it enables us to effect as compared with haymaking is indeed considerable.

WORK ON THE HOME FARM.

Glad indeed are we to say that Wheat harvest is ended on all our farms, and Barley stacks are going up quickly at last, a change to more settled and brighter weather having come. This was much wanted, as so much of the Barley has a rampant growth of Clover among it, so that it has been impossible to cart the Barley as quickly after the mowing as could be desired. This would tend to show that the sowing of layers with Barley should be avoided so far as is possible, but where there is a persistent clinging to a four-course shift sowing layers with Wheat is never thought of. The Wheat has gone to the stacks in such good condition that there will be no hesitation to thresh out a stack or two early, both for seed and market. We are so much pleased with the appearance of our Salvator Wheat that we have ordered it to be threshed for seed, when this is done we shall be able to report upon the yield. The grain is so large that the weight will, we think, prove quite half as heavy again as ordinary Wheat. One especial merit is that the crop is unlikely ever to become beaten down or lodged. We grew it side by side with a fine crop of Defiance Wheat, which was quite beaten down by rain and wind while the Salvator remained erect. It is

a white Wheat, and if the quality proves satisfactory it is likely to assume a leading place. Our crop was on rather poor land, and will not approach the promised 88 bushels per acre, but then it will assuredly be considerably above the ordinary average.

We have sheep folds upon most of our layers now. Some second growths of red Clover which we intended for seed are being so consumed, as so much of it is barren owing to the dull wet weather. The sheep generally are in a sound condition, but we have had a few losses recently from diseased lungs. Of two sheep so much fallen away in condition that we had them killed, one had a large ulcer in the lungs, and the other had much inflammation and one lung grown to the side. The flock having the taint of foot rot has not a bad case in it now. This is owing to close attention to the feet, and the use of Gell's ointment. We saw recently the small flock of a tenant farmer in disgraceful plight from foot rot; dozens of the sheep limped badly, and some went on three legs. The shepherd appeared to regard it very much as a matter of course. Had he been under our control he would have had the option of either keeping them in better condition or being sent about his business.

OUR LETTER BOX.

Manure for Permanent Pasture (A. D.).—The effect of surface dressings of chemical manure at this season of the year is so uncertain that it is decidedly best to wait till next February before using the manure. The plant present in your new pasture in large quantities is the Milfoil or Yarrow (*Achillea Millefolium*), and its presence indicates that your seedsman added the usual quantity—about 1 lb. per acre—of its seed to the mixture. It is a valuable plant for pastures, is eaten greedily by sheep and cattle, grows with equal vigour in all soils, withstands the effects of drought quite as well as Lucerne, and is to be regarded as an indispensable addition to our best selections of Grasses and Clovers for permanent pasture.

Covered Yards (H. R. W.).—To erect a roof at the price we mentioned you must procure all materials at wholesale rates, be your own architect, and have the work done by a handy man assisted by farm labourers. The sort of handy man we mean should be found on every farm, and he should be able to do all ordinary repairs to implements, carriages, gates, and buildings, to do all the stack thatching, and any other work requiring a little more intelligence and handiness than that of the ordinary labourer. A shilling or two a week above the ordinary rate of pay, and something extra for special jobs, keeps the man contented and enables the master to save many a pound. Having saw mills and a timber yard near you may prove no advantage. Our home farm is within a mile of a town where there are plenty of builders, timber yards, and saw mills, yet we effect a considerable saving by having our building materials from a large wholesale firm of importers at a seaport some sixty miles distant. This even applies to roofing tiles, which are both cheaper and of better materials and finish than those to be had from local makers. If local tradesmen allow business to be thus taken away from them they only are to blame; everyone has a right to buy in the cheapest market. The sort of roof we indicate is of course a rough and ready affair, strength and utility being the leading principle. A span roof for a small yard, a ridge and furrow for a large one, stout unsawn posts, principal rafters, beams and king posts large enough to ensure stability, stout angle irons to beams and posts, screw bolts to beams and king posts. Order the timber either in correct lengths or double lengths, all of it rough sawn, none of it to be planed. If the purchase of materials in this manner is new to you, a statement of your requirements to a wholesale firm may prove advantageous, as they may have stock materials a little different in dimensions to your sizes which would answer the purpose equally well and cost much less. We hope these general hints will be useful to you. Plans and specifications are obviously a little outside our province.

REMARKS.

25th.—Bright and fresh.
 26th.—Generally cloudy in morning; fine afternoon, with some sunshine.
 27th.—Fine and generally bright.
 28th.—Bright and pleasant.
 29th.—Bright and warm.
 30th.—Bright early, smoke-fog from 9 A.M. to 10.30; then bright again, but rather oppressive.
 31st.—Bright and fine morning; cloudy afternoon.
 Bright week with no rain, the temperature above the average, although the minimum has fallen nearly 3° below that of preceding week.—G. J. SYMONS.

SPORTS of a distinct character are always valuable in any section of Chrysanthemums, but none has ever assumed the importance, obtained the notoriety, and been the subject of so much litigation as the early flowering Mrs. H. Hawkins, a golden variety of the Madame Castex Desgrange type. Few of those who saw it when first exhibited last year could have anticipated that its history would have become so interesting, that it would have been made the subject of an action to recover heavy damages, or that the opinion of some of the leading Chrysanthemum experts of the present time would be in request to determine its distinctness from or identity with other varieties. All this has, however, taken place this year, and a dispute of an unprecedented character in the Chrysanthemum world will shortly be brought to a termination by the decision of special arbitrators.

The history of the case is briefly this, some of the facts having been long familiar to those concerned with these plants, while others were elicited during the course of the inquiry. At the meeting of the Royal Horticultural Society in the Drill Hall, Westminster, on Sept. 11th, 1888, Messrs. Hawkins & Bennett, nurserymen and market growers of Twickenham, exhibited before the Floral Committee a golden sport from George, or more properly, Gustav Wermig (itself a pale yellow sport from the white Madame C. Desgrange), and a first-class certificate was awarded for it. On the following day (Sept. 12th) the National Chrysanthemum Society held their annual Exhibition of early varieties at the Royal Aquarium, Westminster, and to the Floral Committee of this Society Messrs. Hawkins & Bennett also submitted their new sport, with the result that a first-class certificate was again awarded. At this Exhibition Mr. T. S. Ware of the Hale Farm Nurseries, Tottenham, showed "a new Chrysanthemum" of the same type and colour as Mrs. Hawkins, and in the opinion of most of the members they were the same variety. Messrs. Hawkins & Bennett's plants and blooms were, however, in much better condition and were considered to show the character more fully, and in accordance with a rule guiding the Floral Committee in its action the certificate was awarded to the better of the two exhibits, the slight difference noticeable being attributed to cultural causes. All was clear up to this point, but then the difficulties commenced.

At the time of exhibition, or shortly afterwards, Mr. T. S. Ware's plant was named Golden Fleece, and in October of the same year a circular was issued containing particulars, which led to the legal proceedings subsequently taken. Prior to this it appears Mr. Ware had an interview with Messrs. Hawkins and Bennett, at which he offered £10 for the stock of the certificated variety Mrs. Hawkins, a price considered by the former as ridiculously low, and they declined to sell until they had decided to send it out in the usual way. Mr. Ware's first printed statement issued to the public was as follows:—

"October, 1888. New early-flowering Chrysanthemum of special merit. I have much pleasure in drawing your kind attention to a new early yellow flowering Chrysanthemum, flowering now, and thus grandly filling up an awkward gap which the early frosts have made in taking away outside flowers, such as Dahlias, Asters, and the like. This variety was selected last year, and has this season proved itself quite permanent, and will, I think, with-

out the shadow of a doubt, prove to be identical with the variety which was awarded a first-class certificate by the Royal Horticultural Society on September 11th, 1888, and by the National Chrysanthemum Society on September 12th, 1888. Unfortunately at that time my plants were not in good condition, being somewhat later than those exhibited, so that I was unable to compare notes very fully; the flowers, however, of both sports have been shown to some of our leading Chrysanthemum experts, and they unreservedly assert that the two plants are identical. I have given it the provisional name of Golden Fleece (syn. 'Mrs. Hawkins'), and shall be very happy to send a bloom to any of my customers who would like to see it. The following is a description of it: Another superb sport belonging to the Madame Desgrange section. The colour is of a most intense mellow golden hue, with nothing to approach it amongst the early flowering varieties already in cultivation, quite distinct from, and altogether eclipsing the sulphury yellow of G. Wermig, and flowering about one month later, thus connecting the early flowering with the late varieties. It partakes of all the good qualities of the Madame Desgrange family, but in some soils it is a matter of some 6 inches dwarfier than the other members of that section; it flowers in September and October."

Some complaints seem to have been urged against this circular, and in the spring of 1889 the special trade offer of Chrysanthemums was issued in which appeared an illustration and description of "Mrs. Hawkins" with no reference to the "Golden Fleece," and the same omission was noticeable in the spring catalogue published shortly afterwards. Following this came another Chrysanthemum circular in which "Golden Fleece" was substituted for "Mrs. Hawkins" with the same illustration. In the meantime, Messrs. Hawkins & Bennett had commenced proceedings against Mr. Ware, and having reserved their entire stock for later distribution, contended that their intended sale had been damaged owing to the defendant having adopted the title of their variety, which they also maintained was quite distinct from that sent out from Tottenham. It was ultimately resolved, however, to submit the case to arbitration, Messrs. William Paul, R. Ker, and Steel being appointed to adjudicate in the matter, Tuesday last, September 10th, being the date chosen, when the case was heard in Chambers at 64, Chancery Lane, Mr. Grain appearing for the plaintiff and Mr. Loehnis for the defendant.

Numerous witnesses were called, and it was brought out in the course of evidence that the same sport has appeared in no less than four places. First it was noticed in Mr. Heath's nursery at Southgate, and from this stock Mr. Ware subsequently obtained three "stools" in exchange, under the condition that it was not to be sold before the autumn of 1888. From the same stock Mr. Ware had 500 cuttings early in 1889, and Messrs. Hawkins & Bennett bought twelve old stools in February of the same year. In 1887 Messrs. Laing & Sons of Forest Hill obtained a sport in their nursery of the same character, but did not send it out because their stock was insufficient, though a plant was shown for comparison with the others to prove their identity. Mr. Billingham of South Norwood secured a sport of the same character from G. Wermig in 1887, and also exhibited a plant bearing large flowers, but somewhat older than the others, and consequently a little paler in colour. The evidence of the numerous experts called proved that these were all practically one variety, and several instances were given of identical sports occurring about the same time in different collections of plants.

The next question to be settled was whether it was justifiable for one person to adopt the name of a variety for which another exhibitor had obtained a certificate, and the identity of the varieties being determined this became a comparatively simple matter. It was the general opinion that no other course could be adopted, that the award of a certificate stamped the variety as distinct under its special name, and any other title must be sunk under the accepted one as a synonym.

Many questions were asked to ascertain what was the commercial value of certificates, or the object in awarding them, if others could share in the advantages conferred, and it was

admitted by all that the only special value these awards possess is when the exhibitor of a variety holds the whole of the stock, as he can then command the market and the best price obtainable. In the case of sports in the hands of several people, the usual method is for one to purchase the whole, or to come to some agreement respecting the distribution at the same time, and instances were cited in support of this. The Japanese Carew Underwood, a bronze sport from Baronne de Prailly, was sent out simultaneously by two firms. Lord Wolseley, incurved sport from Prince Alfred, which was in the hands of two private growers, was purchased and sent out by one firm. A third example was afforded by Mrs. H. J. Jones, which was obtained by two nurserymen; one who had a small stock being awarded a certificate, and the other with a larger stock immediately took advantage of it by placing his plants in the market. Granting a certificate in the case of the new French varieties, which may be in the nurseries or gardens of a dozen persons, distinguishes the variety only and confers a general benefit upon all in the trade who have it, and in advertisements or circulars it is customary to indicate those varieties which have been so honoured.

The award of the arbitrators is not yet announced, but it will, no doubt, provide a fair settlement of a troublesome dispute; and though it may be in some respects regrettable that it could not have been arranged without having recourse to law, the case will establish a needed precedent.

METHODS OF RENOVATING FRUIT TREES.

ONCE more the time has arrived for important work in the fruit garden to be commenced, and for taking the first active steps towards carrying out contemplated additions to the stock of fruit trees already in cultivation. About the need for or wisdom of renovating innumerable old, or comparatively old, trees there cannot be two opinions, but when we come to the methods to be adopted in carrying out this wise measure there is less unanimity among the authorities.

Regrafting: partially worn out tree has often been recommended as a good means of re-invigorating it. There is no doubt that Apples will grow on Pear stocks, or *vice versa*. There are a few varieties of Apples of extra robust habit, but as a rule Pears are quite as vigorous, and if the former are grafted on to Pears it will only be for a short time that an improvement in the tree's health will last. This regrafting trees, whether with the same class of fruit or not, is, as far as complete renovation is concerned, a mere "flash in the pan," or, in other words, is certain to end in failure. For the first three or four years the grafts or young branches grow strongly, and so they would if the branches were cut hard back and allowed to grow again, but directly the trees arrive at a serviceable size they quickly collapse; at least, such is my experience. There is very much to be said in favour of regrafting vigorous trees of inferior varieties with superior sorts, this being a ready means of very greatly improving the value of an orchard, but something more than grafting is required in the case of all nearly or quite worn out trees. There may be a few instances where a change in the character of the head of a tree may be of marked advantage, clean healthy branches taking the place of those much cankered or stunted in growth, but as a rule it is below the surface of the ground where there is most need for remedial measures. Especially is the case where many trees are grown either in an orchard or cultivated garden. The roots from much isolated specimens can and do ramble widely in search of fresh food, but this is not often available for orchard trees. Those in cultivated gardens are not so far out of the reach of what they most require, but as it happens the roots of these are driven downwards by the spade or fork, and the roots will not long be in a poor or cold subsoil without most injurious effect upon the top growth. This brings me to that portion of my subject which ought just now to be especially important to gardeners and fruit growers generally.

Root-lifting and root-pruning, for one must accompany the other, are the very best remedial measures that can be adopted both for re-invigorating old trees and for increasing the productiveness of any that are naturally too luxuriant in growth. It is only those trees well furnished with root fibres that are constantly of a fruitful habit, and as deep running roots form few or no fibres the trees they support are either very unhealthy, or else they produce little else but sappy wood growth. Deep root action is the greatest evil that can befall a tree, and if the roots could be kept in an

active state near the surface there would be no necessity to root-prune young trees to make them fruitful, or old ones to re-invigorate them, a liberal top-dressing of good farmyard manure being all that the latter would need every second or third year. In some instances if grafted trees were also heavily manured before they had made much progress, and kept regularly supplied with it, valuable trees might quickly take the place of exhausted old ones, but lifting the roots and relaying these in quite fresh soil is a surer, and, as a rule, the more effective measure. There are plenty of trees that are not worth expending so much trouble over, but I always counsel that undue haste be avoided by those who are disposed to destroy trees that have been so many years in attaining their full size. Young trees are usually from six to twelve years before they produce many fruits, whereas an old tree can be restored to a most productive state in the course of two or three years.

It is possible to be over-zealous even in this direction, as I and many others have found out to their cost. The work may easily be commenced too soon and done too thoroughly in one season, several years necessarily elapsing before the trees recover from the very severe check given them. Several large Pear trees we partially lifted and root-pruned five years ago are only just recovered from it, the fruit produced this season only now attaining something like its full size. No fixed date can be assigned for making a start, so much depending upon circumstances. If the trees are root-pruned before the wood is well matured and the leaves have plumped up the buds they are liable to flag badly, and shrivelling will follow. Frequent syringings and temporary shade in bright weather will partially prevent flagging, but it may yet be insufficient to prevent shrivelling and a very great check to the tree's top and root growth. It is certainly advisable to lift and root-prune while yet the leaves are green, but this season, unless the present bright weather lasts, they will be later in doing their work and falling, and I should not advise the remedial measures being started before the middle of September, the end of that month or early in October being quite soon enough in some cases.

It is a very risky proceeding to wholly lift a large old tree, and it had far better be done piecemeal, or one half this autumn and the other next year. In this case it is also safer to commence operations somewhat earlier, or as soon as the crop that may be on the tree is gathered. A wide trench should be opened far away, or, say, not less than 8 feet from the stem of the tree, one half of the tree being gradually undermined, and the roots carefully preserved till the tap or deep running roots immediately below the bole are reached. Most of the stout roots must necessarily be cut through, but they ought to be preserved to as great a length as possible, and all should have their broken ends clean cut over and then relaid in a horizontal position very much nearer the surface, a liberal quantity fresh turfy loam, crushed bones, and burnt soil or charred garden refuse. If this is done well many fresh root fibres will be formed this autumn, or at any rate the wounds will be callused over, and "root buds" be formed. There will most probably be a marked improvement in the productiveness and quality of the fruit during the first season following root-lifting and pruning, a complete cure being effected by the completion of the work in the autumn.—
W. IGGULDEN.

LINARIA ANTICARIA.

SEVERAL of the species of perennial *Linarias* are well worthy of cultivation and of more attention than they have hitherto received, and among these the comparatively new *L. anticaria* is not the least worthy. I call it comparatively new, as so far as I am aware it was only introduced by the trade about the year 1884, and does not appear to be very widely known. As originally introduced, the flowers are described as white with a flush of lilac and an irregular dark brown or purple spot near the throat, and delicately veined. The variation of seedlings from this description is, however, already so marked that it is highly probable that great variation exists in the native habitats of the plants, as it is hardly conceivable that so many seminal varieties could have been produced in the short time since the plant was introduced. Among my plants raised from seed sown last year there are no fewer than eight varieties mostly fairly distinct. Had it not been for an unfortunate accident to the larger number of the seedlings there would almost certainly have been other varieties, as a friend, out of a very few seedlings, had another distinct variety—a buff ground with purple markings. I have saved a quantity of seed, and as the plants are largely frequented by the bees I have little doubt that some new shades of colour will present themselves.

I do not know that details of the various markings would be

welcome to the readers of the Journal, although I have carefully noted these for future reference, but two or three of the most noteworthy may be of interest. One of the most beautiful is a white ground with bright yellow spots near the throat, the top lined and tinged with bright lilac, spur canary, distinct clear white marks below the spots near the throat. Another is also white with very faint lines and faint spots of yellow near the throat, and is without lilac tinge. This variety was admired by a lady florist as a "beautiful dwarf white Antirrhinum." Another has the spurs yellow and white and the remainder of the flower lilac-purple with deeper lines and spots near the throat. The other variations differ more or less from any described, and all appear worthy of preservation in the rock garden or border of choice dwarf hardy plants.

The habit of the plant makes it suitable for rockwork or for raised stone edgings. It forms a neat tuft of about 6 inches in height, composed of many stems of glaucous, alternate blunt leaves bearing terminal clusters of flowers. These bloom in succession, and a good plant is in flower for some months at a stretch. It appears to prefer a light warm sandy soil well exposed to the sun, and it is doubtful if plants will stand the winter on cold or heavy soils, but a few seedlings might be raised annually or cuttings kept in a cold frame through the winter. On my soil, which is very light, strong plants seemed to suffer little, but weak ones succumbed to the slugs, which were unusually numerous last winter. In one garden further inland all the plants succumbed to the winter, while in another in the same town the only plant in the garden survived. *L. anticaria* is easily propagated by seeds, cuttings, or division, and while I would carefully warn all that it is not a showy plant, I can as surely recommend it to those who can appreciate quiet unobtrusive beauty in flowers, and who are willing to take some little care of plants which are only of doubtful hardiness.—S. ARNOTT.

LÆLIA JONGHIANA.

THIS very little known and beautiful species flowered for the first time in this country in 1873, and it is thus described—Rhizome very stout, creeping, with remarkably thick root fibres. Pseudo-bulbs $1\frac{1}{2}$ to $2\frac{1}{2}$ inches long, approximate, narrow, ovate oblong, compressed, green, clothed with a white membranous appressed sheath, that ends in a short point, and is usually split on one side; a short outer boat-shaped sheath also envelopes the base of the pseudo-bulb. Leaf sessile, short, 3 to 5 inches long by $1\frac{1}{2}$ to $1\frac{3}{4}$ of an inch broad, broadly oblong; tip rounded (rarely acuminate according to Mr. Luddemann) or emarginate, very coriaceous indeed, deep bright green and shining; scape stout, much shorter than the leaf, one to two flowered. Flowers 4 inches in diameter across the petals, which as well as the sepals and convolute body of the lip, are of a bright amethyst colour. Sepals linear-lanceolate, acute. Petals larger and broader than the sepals, broadly elliptic, oblong, obtuse. Lip convolute; lateral lobes very shallow, and, as well as the short emarginate midlobe white, with crisped and waved minutely toothed margins; disk of the body of the lip white, with seven parallel, slender, undulate, golden yellow ridges, which are not prolonged on to the midlobe; column slender, not winged. It blooms during the spring months. Native of Brazil.

LÆLIA PRÆSTANS.

A lovely species, of dwarf habit, sometimes confounded with *L. pumila*, from which, however, it may be readily distinguished by the larger flowers, which are wonderfully thick and fleshy. It seldom exceeds 6 to 8 inches in height, and thrives best when kept upon a block of wood and suspended near the glass. Pseudo-bulbs fusiform, 3 to 4 inches high, bearing a single oblong, acute, coriaceous dark green leaf, which is 4 to 6 inches long. Flowers terminal, solitary, 4 to 5 inches in diameter, very thick in texture. Sepals oblong, acuminate, $1\frac{3}{4}$ inch long, by scarcely 1 inch in breadth; petals ovate oblong, obtuse, ending in a point, about 2 inches long and $1\frac{1}{2}$ inch broad, like the sepals deep rose, in some varieties rosy lilac or light purple, and very thick and fleshy in texture. Lip three-lobed, lateral lobes rolled round the column, extremely thick and wax-like, the whole margin and front deep rich purple, throat yellow, with a few elevated lines on the disc; the reverse side of the labellum is rosy lilac. It usually blooms about the months of October and November, but sometimes it will bloom

in early summer, make a new growth and flower for the second time, in the autumn. Native of St. Catherine's Island, Brazil. 1857.—G. T.

HOLMSKIOLDIA SANGUINEA.

THE *Holmskioldia* represented in the accompanying illustration is the only species of the genus yet introduced, and is by no means common, although it has been grown in this country for upwards of a century. It is an evergreen shrub growing about 3 feet high with deep green cordate leaves. The flowers are crowded on the ends of the shoots in dense racemes 6 to 8 inches in length, and are bright scarlet. Being from the East Indies, *H. sanguinea* enjoys an abundance of heat and moisture, and thrives best if kept in a stove temperature. It is a charming plant when well grown. Cuttings strike readily in the propagating pit if put in some light sandy soil. Well drained pots should be

FIG. 30.—HOLMSKIOLDIA SANGUINEA.

used, and a bellglass or handlight placed over them. When they are rooted they are potted singly in peat and loam of about equal proportions, giving them a shift into larger pots as they require it. They soon make good sized plants, and will produce an abundance of bloom during the autumn months.—G.

THE NATIONAL DAHLIA SHOW.

SEPTEMBER 6TH AND 7TH.

THIS year being the one hundredth anniversary of the introduction of the Dahlia into England, an opportunity arose of introducing a fresh feature into the annual Show of the National Dahlia Society at the Crystal Palace, and it was taken advantage of in an interesting and effective manner by forming a "centenary class," fully referred to in the report. The Show itself was of much the usual character, and of perhaps about the usual merit; but comparisons made from recollections of former years are not easy. The names of Messrs. Turner, Cheal, Keynes, Williams & Co., Humphries, Rawlings, West, Glasscock, and Boston are a guarantee for good quality, and these, with many others,

competed in the various classes. Collectively considered the Show was an excellent one, and particulars of it will be found appended.

The Centenary Class.—This was open to all, as such a class should be, and prizes to the value of £15 were offered. It may be well to quote the schedule in order to give a clear idea of what was expected:—"Collection of Dahlia blooms to occupy a length of staging not exceeding 24 feet; no restriction as to varieties or types, nor as to the method of staging or grouping, quality and general effect to be the leading features. Moss may be employed, and Dahlia buds and foliage may be introduced, but no other kind of foliage may be made use of." It may be said at once that this class unquestionably added a feature of interest to the Exhibition. Moreover, large collections of blooms, composed of all the known forms of these brilliant flowers, must be of greater interest to the general public than ordinary classes of any one section. The Centenary class was looked forward to from its novelty, but a similar one would perhaps not be unwelcome as an annual fixture. On the occasion under notice six beautiful collections were staged. The imposing display of large double forms, the free light masses of single varieties, so valuable in large groups of flowers, and the distinct forms of the Cactus or garden kinds produced a delightful effect. A large and extremely beautiful collection from Messrs. J. Cheal & Sons, Lowfield Nurseries, Crawley, was awarded the first prize. Along the front were stands of Decorative and double blooms. At the back was a bank of singles, comprising many well-known varieties, flanked on each side by groups of Pompon and Decorative blooms. The singles gave lightness and grace to the whole group, the Cactus varieties also contributing good support, and the blending of groups and colours throughout was admirable. A totally different arrangement from Mr. T. S. Ware, Tottenham, was placed second. This was arranged in a series of banks, the central group being composed of Decorative varieties, with groups of singles on each side of it, and pyramidal masses of doubles at each end, the spaces between being occupied by several single varieties, and such species as Zimapani, velvety purple; Mercki floribunda, white; and Glabrata, blush. Messrs. Paul & Son, the Old Nurseries, Cheshunt, were placed third, a position that hardly did justice to their beautiful group. In front were boxes of double and Decorative varieties; at the back bunches of single Pompon and Decorative forms were intermingled. There was quality and beauty of arrangement in this fine group. Messrs. Keynes, Williams & Co. were fourth. Mr. Turner and Mr. Such of Maidenhead were the other exhibitors.

Nurserymen's Classes.—The first of the five classes devoted to nurserymen was for seventy-two blooms, Show and Fancy, not fewer than thirty-six varieties, and not more than two blooms of any one variety. This is not an easy task to fill, and four exhibitors were as many as might be expected. Mr. C. Turner, the Royal Nurseries, Slough, achieved a creditable victory. The Slough blooms were not conspicuously large, but in fresh, bright condition, and well finished. The following varieties composed the stand:—Back row: Clara (very beautiful), Rev. J. Goodday, Sailor Prince, Grand Sultan (2, the first a noble flower), Mrs. Gladstone (2, not quite so good as usual perhaps, but clear and fresh), Harry Keith (2), Seraph, Mrs. J. Downie, Robina (2), Mrs. Langtry, Prince Bismarck, a seedling, Crimson King, Ethel Britton, Colonelist, Prince Bismarck, Maud Fellowes, Diadem, Chas. Wyatt, and Eclipse. Middle row: Sunrise, Florence, Burgundy, Miss Cannell, Jas. Cocker, Chas. Wyatt, Nellie Cramond, Mrs. Jeffard, Mrs. Foster, Jas. Stephen (2), Purple Prince, John Bennett, Clara, Richard Dean, R. T. Rawlings (2), Diadem, Geo. Rawlings, J. N. Keynes, Eclipse, Nelly Cramond, Imperial, and Hy. Eckford. Front row: Mrs. Henshaw, Geo. Dickson, Sunbeam, Ruby Gem, Herbert Turner, Glowworm (2, very fine), John Bennett, Rev. J. B. M. Camm (2), Imperial, Hope (2), Henry Turner, Joseph Green, Hy. Eckford, Mrs. S. Hibberd, Bendigo, Geo. Rawlings, Mrs. Jeffard, Prince of Denmark, Matthew Campbell, Ruby Gem, and Sunbeam. Messrs. Keynes, Williams & Co., Salisbury, were second. Their flowers were on the whole somewhat small, but they comprised several noteworthy examples; for instance, Mrs. E. Mawley, Jas. Cocker, Thos. Hobbs, Wm. Rawlings, and Mr. Glasscock. Mr. Boston, Carthorpe, Bedale, Yorks, came third with a fresh, bright, well-coloured but uneven lot of blooms. The fourth prize went to Messrs. Rawlings Bros., Romford. There was one other lot.

Forty-eight blooms, distinct, were required in the next class, in which four collections were discoverable. Messrs. Keynes, Williams & Co. improved on their previous position by taking first place with a very good and even stand, the flowers faultless in point of finish and condition, though not large. Harry Keith, James O'Brien, Crimson King, Maud Fellowes, Buttercup, Mrs. E. Mawley, and Clara were remarkably handsome examples. Mr. Turner was placed second, his flowers being small; Messrs. Rawlings Bros. third; and Mr. M. V. Scale, Sevenoaks, fourth. Mr. J. Walker, Thame, Oxon, won with thirty-six, not less than eighteen varieties, and amongst a grand lot of flowers James Cocker, Harrison Weir, Harry Keith, Mrs. F. Foreman, and Purple Prince were remarkably fine. This was one of the most meritorious stands in the Show. The second prize fell to Mr. Geo. Humphries, Kingston Langley, Chippenham, who also staged well, but there was a slight roughness observable in some of his flowers. The third prize went to Messrs. Saltmarsh and Son, Chelmsford, and the fourth to Mr. C. Hockney, Stokesby, Yorkshire. There were two other stands, the whole forming a really excellent class.

There were four stands of twenty-four, distinct, Mr. Humphries winning. His blooms were not perfect in point of finish, but good in size and colour, the best being William Rawlings, Crimson King, Mrs. Sanders, and Ethel Britton. Messrs. Saltmarsh followed with Frank

Pearce, James Cocker, and Shirley Hibberd amongst their best flowers. Mr. Walker was third, and Mr. S. Mortimer, Farnham, fourth. Messrs. Cheal & Sons, Crawley, had the best stand of twelve. Mr. J. R. Tranter, Henley-on-Thames, was second with a neat lot; Messrs. J. Gilbert & Son, Ipswich, third; and Mr. Salmon, West Norwood fourth.

Amateurs' Classes.—Five well filled classes represented the amateurs' contribution, commencing with one for twenty-four blooms, Shows and Fancies intermixed. It was a good beginning, as eight stands were in competition, the Judges' inspection resulting in a well-earned victory for that excellent grower Mr. J. T. West, Cornwallis, Brentwood, who staged in his well-known form. The following represented his skill:—Back row: Rev. J. Goodday, Mrs. Gladstone, Harry Keith (a splendid flower of great size and perfect finish), R. T. Rawlings, Wm. Rawlings, Miss Cannell, Prince Bismarck (very fine) and J. T. West. Middle row: Ethel Britton, Jas. Cocker, Rev. J. B. M. Camm (good), Shirley Hibberd, Dorothy, Jas. Stephen, Mrs. David Saunders, and John Henshaw. Front row: J. W. Lord, Mrs. Langtry, Prince of Denmark, Mrs. Shirley Hibberd, King of the Purples, Mrs. George Rawlings, Willie Garrett, and Frank Pearce. These were a smooth, clean, well finished collection. The second prize blooms came from Mr. Thos. Hobbs, St. Mark Road, Lower Easton, Bristol, the best being Harry Keith, Wm. Rawlings, Mr. Glascock, and Hugh Austin. A veteran grower, Mr. Hy. Glasscock, Rye Street, Bishops Stortford, came next, his flowers being very fresh but a little uneven, and Mr. W. Mist, Ightham, Sevenoaks, was fourth.

The amateurs again showed well in the class for twelve distinct Show blooms, eight competing. Mr. A. Ocock, Havering Park, Romford, showed G. Rawlings, Harry Keith, R. T. Rawlings, and Ethel Britton in capital condition with other neat blooms, and was placed first, but only after a close struggle with Mr. T. Anstiss, Brill. The latter's blooms were larger, but also somewhat rougher than those of his rival, the best being a fine bloom of Purple Prince and a very neat example of Jas. Cocker. Mr. Mist came third with a stand of fair average merit, and Mr. S. Cooper, Chippenham, was fourth. There were five stands of six, Mr. H. Heeremans, jun., Chippenham, showing very neat examples of Colonelist, Rosetta, Hope, Mrs. Gladstone, Mrs. W. Slack, and Burgundy for first place. He was followed by Messrs. G. T. Cronk, Orpington; J. G. Fowler, Woodford, Essex; and W. Seaman, gardener to J. Biggs, Esq., Brentwood, in the order of their names; all good stands. Twelve Fancies were best shown by Mr. Glascock—Viceroy, Mrs. J. Downie, and Henry Eckford being his best flowers. His only opponent was Mr. West, and the latter was placed second, although some distance in the rear. The paucity of competition here was made amends for in the class for six, in which eleven competed. Mr. Ocock was first with a splendid stand, comprising Rev. J. B. M. Camm (a grand flower), Peacock, Frank Pearce, Mrs. Saunders, Mrs. N. Halls, and Hy. Eckford. Mr. S. Cooper showed small, but very fresh, bright blooms for second place, and he was followed by Mr. H. H. Steer, New Eltham (third), and Messrs. T. Hobbs and H. Heeremans, jun. (equal fourth).

Open Classes.—As regards general effect these were the most noteworthy classes in the Show, as they embraced the single, Cactus, and Pompon forms. The first, however, were for Show and Fancy Dahlias grouped by colour. For six blooms of any two dark varieties, Show type, three blooms of each, Mr. Walker was placed first with Jas. Cocker and Geo. Rawlings, both remarkably fine. Messrs. Keynes, Williams & Co. were second with Wm. Rawlings and Harry Keith; Mr. Hobbs third with Willie Garrett and Prince of Denmark; and Messrs. Rawlings Bros., Romford, fourth with G. Rawlings and Rev. J. Goodday. There were seven other stands. Mr. West won with light blooms having grand examples of Mrs. Gladstone and Queen of the Belgians, but which afforded little contrast of colour; Messrs. Keynes, Williams & Co. being second with Mrs. Gladstone and Georgina; Mr. Glascock third with Maud Fellowes and Mrs. Gladstone; and Messrs. Saltmarsh fourth with Mrs. Gladstone and Mrs. Slack, the former thus being represented in every stand. There were six others. Tipped flowers were best staged by Messrs. Keynes, Williams & Co., who won with capital examples of Peacock and Mrs. Saunders; Mr. Glascock being second with Mrs. Saunders and Miss Browning; Messrs. Saltmarsh third with the same varieties as in the first-prize stand; and Mr. Walker fourth with Mrs. Saunders and Fanny Start. Ten competed altogether. Messrs. Keynes, Williams & Co. won with striped flowers, staging Rebecca, and Mrs. J. Downie; Mr. West following with Frank Pearce and Hy. Glasscock; Mr. Humphries third with Dorothy and John Cooper; and Mr. Glascock fourth with Frank Pearce and Mrs. J. Downie. Ten competed.

Decorative Dahlias were finely shown by Messrs. Keynes, Williams & Co., Juarez, Mrs. Hawkins, Empress of India, Amphion, Honoria, Professor Baldwin, Asia, Lady Marsham, Prince of Wales, Henry Patrick, Panthea, and Wm. Darvil, all good blooms admirably set up in bunches, won them the first prize in the class for twelve. Mr. Scale followed, the beautiful variety Charming Bride being very noticeable in his stand. Messrs. Cheal & Sons took the third place, and Messrs. J. Laing & Sons, Forest Hill, the fourth. There was one other stand.

There were eleven stands of six, forming a very beautiful display. Mr. Glascock won with Panthea, Amphion, Lady Brassey, Empress of India, Mrs. Hawkins, and Beauty of Brentwood, in admirable condition. Mr. West was second with a scarcely less beautiful stand, Mr. T. W. Girdlestone, Sunningdale, third, and Mr. Ocock fourth. Pompoms were also a very beautiful feature, arranged in bunches with their own leafage. Mr. Turner had a splendid stand of twenty-four varieties, comprising Fairy Tales (new, soft primrose), Admiration, Cleopatra, Isabel, Hamlet, Lady Blanche, Ariel, and Lavinia (back row); Oberon,

Juno, Leila, Rosalind, E. F. Jungker, Vivid, White Aster, and Golden Gem (middle row); Eccentric, Darkness, Whisper, Mabel, Little Duchess, Mikado, Rosalind, and Favourite (front row). Messrs. Keynes, Williams & Co. were a capital second, Messrs. Cheal & Son third, and Messrs. Laing & Son fourth, one other competing.

Messrs. Gilbert & Son won with twelve neat bunches but somewhat crowded, and Mr. Humphries was second, the remaining prizes going to Messrs. Henshaw and Burrell, Cambridge. Mr. West was first with six, Mr. Glascock second, Mr. Apthorpe, Cambridge, third, and Mr. S. Cooper fourth, several others competing.

Messrs. Cheal & Son are famed exhibitors of the lovely single flowers, and they achieved a ready and most meritorious victory in the class for twenty-four. The varieties were Mrs. Kennett, Albert Victor, White Queen, Amos Perry, Jas. Seobie, Queen of Singles, Mrs. Coninck, and W. Irving (back row); Duchess of Westminster, Enchantment, Sunningdale, Mrs. Rose, Ida, Cetewayo, W. C. Harvey, and Excelsior (middle row); Duchess of Albany, New Year, Lady Montefiore, Formosa, Mrs. Henshaw, Hugo, Victoria, and Miss Ramsbottom (front row). The second prize was withheld, but Messrs. Gilbert were third. Mr. Seale won with twelve, a most charming stand, beautifully set up, Mr. Burrell being second with large but coarse and crowded flowers. Mr. Girdlestone won with six, fresh blooms of good size, not too large, and in excellent condition. Mr. Henshaw was a close second, Mr. Glascock third, and Mr. E. Mawley, Berkhamsted, fourth.

Messrs. Cannell & Sons, Swanley, had a very extensive and beautiful collection of Dahlias, not for competition, comprising all cultivated forms. First-class certificates were awarded to Messrs. Keynes, Williams & Co., for Show Dahlias Alice Emily, Duke of Fife, and Majestic; to Messrs. Cannell & Sons for Cactus Dahlia Mrs. Douglas; to Mr. Turner for Pompon Dahlia Cleopatra; to Mr. T. S. Ware for single Dahlia Miss Jefferies; and to Mr. T. W. Girdlestone for single Dahlias Gruppo, Lady Helen, and Yellow Perfection.

DAHLIA CENTENARY CONFERENCE.

ON Friday afternoon, September 6th, the National Dahlia Society held a Conference in the Crystal Palace, when several papers were read upon the history and culture of the Dahlia. Shirley Hibberd, Esq., took the chair at 3 P.M., and after a few introductory remarks read his paper upon the "History of the Dahlia," which is given *in extenso*. He was followed by Mr. Harry Turner, Mr. J. West, and Mr. Cheal, who gave much information of practical value, as will be gathered from a perusal of their papers.

HISTORY OF THE DAHLIA.

[A paper by Mr. Shirley Hibberd, read at the Crystal Palace, September 6th.]

ALTHOUGH the history of the Dahlia as a garden flower extends over only one hundred years, it is an eventful history, and the historian may more easily indulge in profuseness of detail than compress within moderate limits the points that are likely to prove at once the most useful and interesting to the participants in this Centenary Conference. Happily there are not many knotty questions presented by the facts on record; but these facts have been variously presented, and in glancing at the existing histories, so-called, of this flower, I find much confusion and contradiction, and often a sad misapprehension on the part of the historian of the bearings of the particulars at his command. Thus in the "Gardeners' Magazine" of October 9th, 1880, will be found two short histories of the flower, one from Mr. Max Deegen, of Köstritz, the other from Dr. Comstock, whose "Illustrated Botany," published at New York in 1847, contains much valuable information of special interest to florists. Max Deegen begins by saying that the Dahlia was introduced to England in 1787; to France in 1802; to Germany in 1804. It cannot be allowed in an assembly solemnly convened for the glorification of the Dahlia that the promoters are too late by so much as two years. No; if Max Deegen and the "Horticultural Magazine" of 1839, which appears to be his authority, are in the right, it will be but proper for me, as President, to dissolve this assembly and declare the centenary as a thing silently accomplished two years since, leaving us nothing in that way unless, perhaps, we might justify our meeting by making arrangements for the bicentenary in 1987. It will be my duty to abolish Max Deegen, and put this celebration on a firm historical foundation.

We cannot move a step without referring to the hooks. There appears to be no earlier description of the Dahlia than that by Francisco Hernandez, physician to Philip II. of Spain, in his four books on the plants and animals of New Spain, published in Spanish in the year 1615. In this work our flower appears under its Mexican name of *Acotli*, and the notice is particularly interesting, for two species are figured, *D. variabilis* and *D. crocata*, and both have single flowers. We appear thus to secure somewhat of a triumph for the florists, but, unfortunately, in a work founded on that of Hernandez, and published at Rome by Vitalis Mascardi in 1651, there occurs a figure of a double flower, but whether it was obtained as such direct from the domain of Nature, or through the garden from the hands of man, there is no sufficient record, and we may not, therefore, say that the florists had commenced operations at so early a date. We speak of this as a double, but the drawing is so bad that it may be single. It is of importance to observe that we lose the Dahlia for 130 years, when it turns up again in 1787, not, as in the former case, for the special advantage of Spaniards, but this time for Frenchmen in a most exclusive sort of manner. Nicholas Joseph Thierry de Menonville was sent to America to secure the cochineal insect. He was to act on the principle of Iago when he said, "put money in thy purse," for the plant and the insect were both

to be secured, and they were secured, with a few other things that were worthy of the labour. M. Menonville published in 1787 a treatise on the culture of the Nopal and the "education" of the cochineal, and therein described the Dahlias he had seen in a garden near Guaxaca, which, he says, had large Aster-like flowers, stems as tall as a man, and leaves like those of the Elder tree. Thus the deceptive date is obtruded on the history, but there is no record of the Dahlia being brought into England in 1787, but after a lapse of two years we hear of it again as actually introduced to this country by a lady whose name should this day be remembered with gratitude as a generous contributor to our great garden of florists' flowers.

In the year 1789, Vincentes Cervantes, director of the Botanic Garden at Mexico, forwarded seeds of the Dahlia to the Royal Gardens at Madrid, then under the direction of Abbé Cavanilles. The Marquis of Bute was at this time Ambassador from England at the Court of Spain; and the Marchioness, who cherished a true sympathy with floriculture, obtained some of these seeds, which she cultivated in pots in a greenhouse, but failed to keep them beyond two or three years. The Marchioness of Bute was in correspondence with the professors at the different botanic gardens in Europe, and thus had opportunities for acquiring, and perhaps of diffusing, information on such matters, and her loss of the plants may therefore be accepted as in some part testifying to the prevalence of misconceptions as to the requirements and characteristics of the Dahlia. In 1802 an English nurseryman, John Fraser, of Sloane Square, a collector of American plants, obtained from Paris some seeds of *Dahlia coccinea*, which flowered in a greenhouse in 1803, at his nursery, and supplied a subject for the plate in the "Botanical Magazine," t. 762, which secured to the plant a proper place in the English garden. Thus it happens that in Aiton's "Hortus Kewensis" the Dahlia obtained a place, two species and three varieties being entered in the second edition, published 1813.

The Abbé Cavanilles named the plant in honour of M. André Dahl, a Swedish botanist, author of a work on the Linnean system, published in 1784, and Cavanilles figured it in his "Icones et Descriptiones Plantarum," the publication of which was commenced at Madrid in 1791. Comstock tells us that it was Humboldt who sent the seeds to Madrid in 1789, but Humboldt had not at that time set a foot on the American continent, for he was pursuing his studies under Heyne and Blumenbach from 1787 to 1789, and he did not visit America until February, 1800.

For ten years the Abbé Cavanilles managed to keep his Dahlias, and perhaps I might say that in that time he actually improved them, for one of them produced semi-double flowers in October, 1790; and in the January following was figured in the "Icones" as *D. pinnata*, which was the early name of our *D. variabilis*, and thus we fix the date of the first doubling of the Dahlia in Europe as occurring in the first year of its flowering at Madrid. The variety named *rosea* was very soon afterwards established at Dresden, for in the year 1800 it was sent from Dresden to Berlin with the *D. pinnata* and *D. coccinea* already cited, the entire collection of Dahlias of that date consisting of these three only. In 1802 Cavanilles sent them to the Jardin des Plantes at Paris, and to M. Decandolle at Montpellier, and thus the flower was fairly started on the way to become known throughout Europe.

In the year 1799 Humboldt and Bonpland left Madrid in the ship Pizarro for the American continent, and commenced those explorations which have secured for them as scientific travellers immortal renown. In descending from the table land of Mexico towards the Pacific coast, they found the Dahlia in a prairie between Areo and Patzcuaro at a height of 5000 feet above the level of the sea, a fact which at once explained the failures of Lady Bute and others to grow it as a plant needing much heat and a constantly close atmosphere under glass. Kew had obtained the plant, and had lost it as a consequence of stewing or roasting it, as moist or dry cookery might happen to be in favour. At Paris the same thing had occurred, for M. Andre Thouin, director of the Jardin des Plantes, placed his Dahlias in a stove, the tropical idea haunting him, as apparently all others had been haunted, so that it was in the nature of a miracle that the plant escaped the killing treatment to which it was so generally subjected. Many of the most useful plants have passed through a similar ordeal, one of the most notable examples being the *Aucuba japonica*, which proved a most troublesome customer, always at death's door while confined to a hot prison, but was found capable of taking care of itself when turned out and left to contend with the elements. In 1804 M. Thouin published a treatise on the subject in the "Annales du Museum d'Histoire Naturelle," in which he presented engravings of this new favourite; but the best he could say for it was that he had persuaded it to live.

This appears to be the proper place for a brief discourse on the name of the plant. We call it colloquially the Day-li-a, but as it is named after Dahl the vowel sound should be broad, *Dah-li-a*; but custom is against its use in that way, and to avoid appearing pedantic most of us adhere to the *Day-li-a*. It should be understood that this name has priority of all others, and we are justified by history no less than by custom in using it. The genus of the same name instituted by Thunberg represents a group of Witch Hazels—plants far removed from the subject of our present attention. The genus *Dalea*, named after Dale, the friend of Ray, is in the Fabaceous order, and also far removed from our noble Mexican flower. A competing name, *Georgina*, ran Dahlia a race for a season, for Professor Willdenow of Berlin, owing to a misapprehension, felt the necessity of suppressing the name adopted by Cavanilles, and of substituting *Georgina* in honour of Professor Georgi of St. Petersburg, which a writer in "Revue Horticole" declared, was

adopted by the English cultivators to rob Dahl of his honour and exalt in his place that of George III., King of England, in whose reign the flower was introduced. The name Georgina was much used in Germany and England, and so late as 1832 I find it entered in an index to "Loudon's Gardeners' Magazine." That, as you all remember, was the year of the Reform Bill, and a reform was effected in this matter, for in the year following H. Reynard, Esq., President of the Beverley Horticultural Society, proposed to reinstate the original name, and thereupon the reform was accomplished. In "Loudon's Gardeners' Magazine" for 1834, page 607, will be found a record of the event, with the following declaration by Mr. Loudon:—"Our authority for adopting the name Georgina was Mr. Sweet; but Mr. David Don has proved to us that the name Dahlia was applied one year before that of Georgina. The name Dahlia, therefore, will in future be used by us."

The year 1804 forms the second epoch in the history of the Dahlia. In that year it was figured in the "Botanical Magazine" from Mr. Fraser's specimens that flowered in Sloane Street. Seeds were again sent from Madrid, this time by Lady Holland to M. Buonaiuti, librarian to Lord Holland at Holland House. This gentleman raised all three varieties, and they flowered satisfactorily and were figured in the botanical periodicals of that day. From this time the cultivation tended in the direction of the exhibition that is here to-day, for the end of all who possessed the plant was to effect some improvement, the great aim being the production of double flowers. Now, although I have spoken of one of the early figures as apparently showing a semi-double flower, this must have been transitory, for in 1806 the gardeners at Malmaison and St. Cloud were striving after double flowers, and appear not to have got beyond the three varieties they began with—namely, *coccinea*, *purpurea*, and *crocea*. But in 1812 M. Donkelaar of the botanic gardens at Louvain, Belgium, raised a number of plants which all produced single flowers. The next year he made a further essay, and obtained some semi-double flowers; and again he operated and secured flowers perfectly double, and the honour appears beyond all doubt to be due to him of launching the Dahlia on the tide of time as a fine florists' flower, one quality of which must be a capability for infinite variation.

This, we will say, brings us to the year 1814, which we may term the third epoch in the history of the flower. It had become established at Erfurt and Leipzig simultaneously with its establishment at Louvain in 1812, and Haage had raised a flower that was more than single if not quite double. It was admired, however, chiefly for its violet colour, which was at that time new to the Dahlia. In 1814 the continent was thrown open by the approach of the Allies to Paris, and the British amateurs found Dahlias in plenty in French gardens, many of which soon found their way to this country, and were taken charge of with enthusiasm by the hopeful florists. Amongst the French amateurs who at this time cultivated this flower with assiduity mention should be made of M. Lelieur of Sèvres, near Paris, and the Comte de Vandes, who imported French varieties into England, and communicated specimens to Dr. John Sims, for the two figures published in the "Botanical Magazine" in the year 1817. It has happened often in the history of the arts and sciences that they have had birth on the continent of Europe, and have reached us when somewhat advanced; but that having made a beginning the people of this country have outstripped their foreign benefactors in a lively interpretation of the Baconian maxim, "The true end of science is to enrich human life with useful arts and inventions."

We must keep in mind that about the year 1815 double flowers were beginning to appear; but I shall invite your attention to the figure of Dahlia *superflua*, the "crimson fertile-rayed Dahlia" that appears in the "Botanical Register" for 1815, for it represents our "Show" Dahlia, the *D. variabilis* in its best form as a single flower not far removed from its wild Mexican form certainly, but in a grand condition as regards its rich crimson colour, its great spread of narrowish elliptic rays, and the small but brilliant golden centre. Such a flower would now be prized, and would make a new class of singles. If history is once more capable of repeating itself, surely this original Dahlia that we have improved out of existence will be restored to us. Sydenham Edwards, the then editor of the "Register," was a man of taste with few prejudices, and we may regard this figure as representing the Dahlia that was considered the best of that day.

From this time the history rises to a kind of stately march, the flower acquires extensive popularity, and as autumn approaches the whole country appears to glow with Dahlias, for tens of thousands are exhibited, and the talk of all the world is about them. The excitement that has prevailed in recent years in connection with exhibitions of the Chrysanthemum is as nothing when compared with the frenzy of forty years during which the Dahlia was the greatest of all the exhibition flowers. From 1820 to 1860 was the term of the highest popularity of the Dahlia. In the "Annual Dahlia Register" for 1836 we find the favourites advertised by the following traders:—Brown of Slough; Cooe of Milford, near Salisbury; George Glenny of Isleworth (who reports that he selects from upwards of 3000 double flowers); John Harris of Upway, Dorset; Heale & Son of Calne; James Levick of Sheffield; Bernard Saunders of Jersey; Henry Skillman, Marlborough; George Wheeler, Warminster; the prices ranging from 3s. 6d. to 21s. per plant, the average for established varieties being then about 5s. to 3s. The petals of the period were generally less in size than the flowers of the present day, and often had pointed petals that were boldly cupped and far away from the smoothness and density that now prevail. One of

them, Brown's Glow-worm, was the precursor of the Cactus series, and comes near to Juarezi in all its characters.

From the year 1832 the advance in floral qualities was rapid and decisive. There was no conflict between "North and South" as to the judging. The type of flower in fashion thirty years ago is admirably shown in the treatise on "The Dahlia," by Robert Hogg, published by Groombridge, 1853, for herein we find the true precursors of the splendid show flowers that now rank highest in the esteem of cultivators; the petals are no longer pointed, but rounded and smooth, and so even with the periphery of the flower as to secure for it from every point of view an unbroken outline, while the crown is higher and more refined, and in respect of size the flower comes very near to the present standard. In this work Mr. John Edwards, President of the National Floricultural Society, at one time collaborator with Mr. E. S. Dodwell, pronounced Yellow Standard the finest flower he had seen until he obtained from it a variety named Mrs. Hansard, which is figured in Hogg's book as a flower of a soft primrose colour, with white tips, reminding me of the present Mrs. Saunders. Mr. Edwards reports that he sold this for £5 to a Dahlia trading firm, known as "The Metropolitan Union," respecting which it would be out of season for me to give any particulars.

It is an interesting question how many species of Dahlias we may have in cultivation. Taking the species reported in the order of their appearing, we have Dahlia *coccinea*, otherwise *D. frustanea*, the barren-rayed Dahlia, introduced to Madrid, and figured by Cavanilles in his "Icones." The figure of this in "Botanical Magazine" of 1804 (t. 762), displays such a flower as we may now find in any garden where seedling singles obtain attention, and it is one we should now discard as too small for any purpose. The more famous *D. variabilis* or *D. superflua*, the fertile-rayed Dahlia, was probably also one of the three secured for the first Madrid set, and as figures of it abound I select three only for special mention in connection with the earlier history. "B. M." of 1817 contains two figures, one of a single red flower with broad petals, coming near to a show flower of the present day; the other a double purple of small size, with narrow pointed florets, and such as we may now speak of as in its day a quite promising flower. A grand figure of the single *D. superflua* is that in "B. R.," t. 55 above referred to, and the date 1815 doubtless shows that it was obtained from Paris. The plant introduced by Fraser in 1802 was *D. frustanea*, the barren-rayed Dahlia, which in common with the others had been lost to cultivation. These two appear to be equally variable, and are probably not specifically distinct, so that we may encourage the belief that the Dahlia, as a show flower, is of pure descent, its variations being the consequence of a potentiality of its own and not of any mixing of species or hybridisation.

In 1837 was introduced from Mexico *D. Barkeria*, a pleasing form, probably not specifically distinct from the foregoing. In 1840 *D. glabrata* was obtained from Mexico, and figured in "B. R.," t. 29, and "B. M.," t. 3878. It is smooth and distinctly lobed in the leaf, and has a neat and pleasing habit, being smaller every way than *D. variabilis*, of which it is a variety. The noble *D. imperialis* is certainly distinct, and withal its imperial qualities, it does not now concern us more than to record that it first flowered in the Zurich garden in 1862, and has not as yet become established as a garden favourite anywhere in Europe through lacking the first conditions of manageableness and seasonable display. To our dear old friend, the late John Salter, of Hammersmith, belongs the credit of having first taught the Imperial Dahlia how to behave as a garden plant.

Between the great days of the Dahlia and its eclipse for ten years that closed with the institution of this Society, it was seen how little to be trusted were great corporations, having universal aims, with the interests of such a flower. From the beginning of the world until now it seems that the florists have had cause to complain of the indifference of such representatives of horticultural omniscience as the Royal Horticultural, Royal Botanic, and Royal Manchester Societies, the Crystal Palace, the Alexandra Palace, and the organisations for great floral fêtes, and the diffusion of light from and for the garden in all our great centres of light and leading. The practical outcome of the long-cultivated discontent is seen in the National Societies for the representation of the Tulip, Auricula, Carnation, Dahlia, Chrysanthemum, and other popular favourites. The Crystal Palace became a kind of home for the Rose and the Dahlia, in consequence of the appearance of these flowers at seasons when the great public were apt to be moved by pleasant weather to recognise, and as we sweetly say "patronise," the glories of the garden. The Dahlia shows at the Crystal Palace in a long run of years were delightful as bringing together Dahlias, Gladioli, Hollyhocks, and other autumnal flowers; but they came to an end in the year 1869, simply because, as the managers reported, they had ceased to pay. Thereupon was formed the "Metropolitan Society for the Encouragement of Florists' Flowers," the principal promoter of which was our excellent friend and faithful florist the Rev. H. H. D'Ombraim. This Society held its first Exhibition in the Crystal Palace on September 7th, 1870, and though Dahlias were the leading subjects, there were also good displays of Roses, Hollyhocks, Asters, and Gladioli. The same Society was in action in the Crystal Palace in 1871 and 1872. In 1873 there was no show, for arrangements had been made for holding a show at the Alexandra Palace, but the place was burned to the ground, and it was impossible to hold a Dahlia show amid the ruins. In 1874 there was no exhibition. In 1875 the Metropolitan Society held an autumn Show in the Alexandra Palace, and that was its last act and deed, although the dying speech was not then pronounced; in fact was never pronounced, for the thing died quietly.

But the Dahlia did not die, nor were the ten years of eclipse a loss to its history, for, in truth, while under the cloud and obscured from the public vision, it was like any other honest flower that darkness has fallen upon, preparing itself for the light of a new day. In that wonderful fifteenth chapter of the first epistle to the Corinthians, St. Paul, seeking for a familiar image of an occult fact, says, "that which thou sowest is not quickened except it die." It will not be irreverent to perceive somewhat of an illustration of this appeal to Nature in the eclipse for a season and ultimate recovery of the Dahlia in the sunshine of public favour, because it was in the mind and heart of man that both took place. There was seen upon the horizon of the world of flowers the original Dahlia of 1789; the simple Mexican flower known as the Single Dahlia suddenly acquired popularity, as though its beauties were perceived for the first time, just as some particular star may become visible and obtain universal attention that would not have been seen except through the accident of an eclipse. The single Dahlia lighted us through the darkness until the florists' Dahlia emerged from the gloom, and a way was prepared for a new study and a new love of this magnificent flower, one result of which is that doubles and singles now divide empire between them, as in the celestial order of the earthly seasons the month of May, the "sweet of the year," is ruled by Gemini the twins.

Concurrently with the revival of the single flowers as subjects of special attention, there came into the floral firmament a quite new star known as the Cactus Dahlia, and this, having given birth to a numerous progeny, the Cactus family may be said to form a constellation for us, perhaps, as beautiful as the Pleiades, but already exceeding them in number. Indeed, I have seen as many as twenty varieties of the Cactus group in one border. It was on the 3rd of September, 1880, that the present star arose on our horizon. Upon that date Mr. H. Cannell, of Swanley, presented at the Fruit Show in Alexandra Palace the first flowers of Dahlia Juarezi seen in this country. This distinct and beautiful variety is not a descendant of Brown's Glow-worm, as may appear to be suggested by a remark I have made, but is an independent and original introduction from Mexico in the year 1872, by Mr. J. T. Vanderberg, of Juxphaar, near Utrecht, with whom it flowered in 1873. Messrs. Ant. Roozen, of Overveen, obtained it, and supplied roots to Mr. Cullingford of Kensington, who thus became the introducer of the noble flower to England, and through him it passed into the hands of Mr. Cannell, who secured for it a place of high rank in public favour. It was figured and its history recorded in the *Garden* newspaper, May 7th, 1881, since when there has become established a considerable family of Cactus varieties, greatly to the advantage of our gardens and exhibitions.

To return to the cold current of dates and circumstances: in 1876 it was seen that the Metropolitan Society for the Encouragement of Florists' Flowers had closed its brief career, and the Dahlia was in the position of virtue in a wicked world where none could deny its beauty, but there were not many who would fight in its defence. If I were asked to give an explanation for the collapse of this thing I should say that its great size made a small thing of it; the aim was to gather into one body a number of elements that certainly were not and are not discordant; but they are without any necessary principle of cohesion, and it appears to be impossible for cultivators of Tulips, Auriculas, Carnations, Dahlias, Hollyhocks, and Chrysanthemums—to name a few subjects only—to pull together and share in a common fund with combined energies for the promotion of flowers that demand for their full measure of justice individual enthusiasm and sympathy, in place of the corporate omniscience measured with red tape that is an inevitable characteristic of societies formed for large and general purposes. These considerations tend to show that special societies are absolutely needful in floriculture, and the National Dahlia Society, which came into existence in the year 1881, and held its first Show in the Crystal Palace, September 8th and 9th, 1882, needs no better justification than a plain record of the facts that immediately led up to its formation. May its shadow increase! I beg pardon, it casts no shadow, for, like the sun, it is a source of light. May its light shine strong and far, and prove continuous, for the advantage of this nation that has so readily yielded to the persuasions of town life, and would doubtless perish of inanition were the horticulturists ever to slacken in their efforts to render town life and trade pursuits endurable by the disguising of their harsh lines and discordant colours with the wreaths of flowers that seem to bring the breath of Paradise into our midst in aid of bodily health and spiritual joy. Alas! alas! at the graveside we are accustomed to say in the midst of life we are in death. Here, amid these glorious flowers, I feel compelled to show the money-box, for as lovers must dine—and the soul of poetry in some measure lives on vulgar pen and ink—and perhaps in its poverty has to steal paper—so the Dahlia needs pecuniary support, and I ask you all to join at once the National Dahlia Society, and I would now exact a pledge from every old member to bring in a new member, and every new member to bring ten at least, for when a man enters a thing of this sort his connection is like young humanity, and should readily take contagion of his example.

THE SHOW DAHLIA.

[By Mr. Harry Turner.]

THE subject of this paper being only to treat upon Show and Fancy Dahlias as show flowers, I shall confine my remarks strictly to this subject. The first double or semi-double flowers were obtained about the year 1814 by Mr. Donkelaar of the Botanic Gardens, Louvain, and from three plants which bore double flowers many varieties were raised,

and were imported into this country during the winter of that year, the number of Show and Fancy varieties steadily increasing until we find sixty varieties were cultivated by the London Horticultural Society in the year 1826. Various shades of colour and the quality of the flower gradually improved until the year 1832, when the most decided advance was made by the raising of Springfield Rival, a crimson flower described as superb; and in the year 1841 the number had so increased that one grower claimed to have in his garden 1212 double varieties.

After that year many Show and Fancy flowers were raised, and in the year 1840 we find then some popular flowers were exhibited—viz., Sharp's Beauty of the Plain in eighty-nine stands, forty-four of which were first prize stands. Cox's Deliance, a yellow flower, was also exhibited sixty-seven times in forty-one first prize stands. Two of the best flowers in 1841 being Conqueror of the World, a yellow ground slightly tipped, and Rival Revenge, a yellow flower very much ribbed, and which would be discarded from any stand of the present day. Another of the same date, Burnham Hero, having a very bad outline and rough open petals. In the next year 1842 Whale's Atila was sent out, a lilac ground with a faint crimson stripe, and also Beauty of Wakefield, a large loose petalled variety with a Picotee edge of lilac, and Princess Royal (Hudson's), a rough flower. The next flowers of importance were Beeswing, a dwarf growing variety with crimson flowers, which was exhibited in all the winning stands in 1845; Essex Pride was also good at this time. Amongst the new and improved varieties in 1846 was Cassandra, Magician, Marchioness of Cornwallis, a blush white, not unlike our present Mrs. Gladstone in colour, but not approaching this latter variety in quality, and Princess Radziwill, a white ground flower tipped with rose, but with a long pointed petal. About this time the flowers had so much improved upon former varieties, that only one variety exhibited in the first prize stand of the same number of blooms in 1846 was exhibited six years previously, and that variety was Springfield Rival. The next year, 1847, brought out Scarlet Gem and Berryer, the latter a very dark flower, but with a very ribbed petal; the next variety of note was Shyllock, a scarlet flower that obtained fourteen first prizes and first class certificates; in the same year Toison d'Or, a French variety, obtained some notoriety. In the next year Mr. Seldon was introduced, a very constant flower, which remained in cultivation for fifteen or sixteen years. In 1851 Barmad, raised by Mr. Holmes, was the most successful flower; it was a tipped variety, after the style of our present Mrs. Shirley Hibberd, but not so constant or good in quality. Mrs. Hansard of this year, a Fancy variety, yellow tipped with white, was a great addition to this class. Bob, a scarlet variety, was about this time grown very successfully, it was a very tall growing variety. The next year, 1853, was an important year; John Franklin, Queen Victoria, and Miss Caroline were some of the principal introductions.

The outline of the flower about this time was much improved, and in 1856 a standard flower, which has been grown to the present time, was raised by George Holmes, Esq.,—viz., Lord Palmerston. After this came Lord Derby, Leah, Earl of Pembroke, George Rawlings, Harriet Tetterill, John Wyatt, Lady Gladys Herbert, Mrs. Henshaw, Umpire, a chaste flower, but rather small; Fanny Sturt, Gem, Sultan, and Queen Mab, most of these varieties being grown up to the present time. The great improvement which has taken place in the Show and Fancy Dahlia in the last twenty-five years is in the outline, well-shaped petal and perfect centre, the flowers of the present day requiring little or no dressing in comparison to the time it took thirty years since to prepare a stand of Dahlias for exhibition. The improvement in the flower has also had some effect on the habit, and the Show varieties of the present day are not nearly so tall in habit as those grown twenty-five years since.

I might say a few words as to the preparation of the plant to produce show flowers, although the subject has been described in another paper under the heading of cultivation. The plants intended to be planted out to produce show flowers should be transferred from the small 5-inch pots (in the early part of May) into 48's or 32's, and placed in a cold frame until planted out early in June. Nearly all the varieties make strong plants, and succeed well if grown from cuttings, but a few varieties such as Bendigo, Mrs. Foster, Burgundy, Herbert Turner, &c., which are very double, or are apt to come with green centres, are better grown from pot roots or old divided ground roots. The plants should be planted 5 feet by 4 feet apart: if in a border, arranging for the tallest flowers at the back. After the ground has been squared out dig holes about 2 feet square and the same in depth—into each hole put a spadeful of light potting shed or other soil mixed with a little manure—this is to give the plant a start—break up the soil taken out of the hole before returning it, and after the plant is planted lightly tread when replacing it. A light stick will hold the plant for a few days, and when planting is finished put a stout stake 4 to 5 feet high to each plant, and tie the stem of the plant to the stake rather loosely to allow for the stem to swell in due course. As soon as the main stem throws out laterals add four smaller stakes to secure the side branches to keep them well tied out, so that plenty of light and air are admitted to the plants during growth.

There is no general rule for disbudding, every variety has to be studied in this respect—to commence to disbud some coarse-growing varieties, such as Champion Roll'o, Royal Queen, &c., as soon as the buds appear would make the flowers coarse the whole season, whilst all varieties should be sparingly disbudded at first by taking only one bud away, and then within three weeks of the exhibition the grower can

choose the bud which is perfect and will be likely to be in flower about the date of the exhibition, and remove all the other buds. Should the variety be a thin and small flower then remove all the side shoots down from the bud to the stem; but should the variety be inclined to become coarse only thin sparingly until a week or so before the show. This is most essential to a Show Dahlia. The soil should never be allowed to be dry at their roots from the time of planting, and I think I might here state that after the plants have been staked and tied out the surface of the soil should be forked over and the plants top-dressed with a good dressing of stable manure, this will keep the roots moist and encourage the roots to the surface to feed. Should the weather be hot and dry the plants should be sprinkled overhead every night in addition to the watering at the roots, which at first should not be excessive, but sufficient to keep them moist and growing. Heavy watering should be commenced three weeks before the exhibition, as the plants will be sufficiently large to take plenty of water, and should be continued until a week previous to the show, the last week lightly sprinkling round the plants to keep them fresh and moist; too much water a few days previous to the show has a tendency to cause the flowers to shoot their petals after being cut for exhibition.

To protect the buds from earwigs, caterpillars, green fly, thrips, &c., a muslin bag 6 inches by 8 is best, and should be placed over the bud as soon as it shows colour. The bag should be fastened with bast or raffia round the stem of the flower, and must be taken off every morning to see if any insect has by chance got into the bag, and the flower examined to see if it is growing properly, and as the flower progresses the bag should be lifted every morning, so as not to check the growth of the flower. Shades are best made of a stout wire frame with a thick canvas covering, and should the weather prove very hot a few leaves of Rhubarb should be laid on the shade over the full grown flowers. Shading should be commenced a week previous to the exhibition. Some tipped or light edged flowers are much improved by a flower pot (24) placed over them on a table a week or ten days before a show, with a piece of glass over the hole in case of rain.

The stands on which the flowers are exhibited are usually painted green, and are made of one uniform width—viz., 18 inches, and should be supported by legs 9 inches at the back and 3 inches in front, holes being made to receive the flowers 6 inches apart, and for a stand of twelve flowers, 24 inches long. In selecting blooms for exhibition place deep circular flowers at the corners of the stand, and introduce as much diversity of colour as possible, selecting quality before size, a large coarse flower often spoiling what would otherwise have been a good stand. The perfection in a show flower should be fair size, globular with good depth, the petals short and cupped, smooth on the edge, the outline a perfect globe, the centre high but not above the face of the flower, the centre should be close, and the petals radiating from the centre should expand by degrees; types of the most perfect flowers being *Mrs. Gladstone*, *Bendigo*, *Joseph Green*, and *Sunbeam*. The colour of a self should be bright and clear, of one uniform shade from the centre to the back petals; if an edged flower the marking should extend round the edge of each petal.

I may here name the best twenty-four Show Dahlias in cultivation at the present time:—

Maud Fellowes (Fellowes), French white, tinted and shaded with purple, perfect centre, and a grand show flower, very constant.

Clara (Rawlings), rosy peach, a large constant flower, of good petal and outline.

Constancy (Keynes), yellow ground, deeply edged with lake, large.

Flag of Truce (Wheeler), white, occasionally tipped lilac, fine.

George Rawlings (Rawlings), very dark maroon, a full size flower, fine.

Goldfinder (Fellowes), yellow, tipped with red, large, finely shaped.

Herbert Turner (Turner), French white, with a soft tinge of lilac; a noble show flower.

Imperial (Keynes), deep purple, with a pretty shade of lilac; large, and of splendid form.

James Coeker (Keynes), purple, large, fine form, constant.

James Vick (Keynes), purplish maroon, full and symmetrical, fine.

John Neville Keynes (Keynes), yellow, of fine form.

Joseph Green (Keynes), bright crimson, full centre and good outline.

Lustrous (Turner), deep scarlet, almost a crimson, fine outline and good petal.

Miss Cannell (Eckford), white ground deeply edged with purplish crimson.

Mr. G. Harris (Rawlings), crimson-scarlet, a deep full flower, fine form, and constant.

Mrs. Gladstone (Hurst). This is admitted to be the most perfect show variety yet raised. The colour is a very delicate soft pink, in form a model, and very constant.

Mrs. Harris (Harris), white ground, lilac edge, a very fine flower.

Mrs. Langtry (Keynes), creamy white, edged with crimson, full size, good form.

Prinee Bismarck (Fellowes), puce, shot with purple, full size, remarkably constant, and of the finest form.

Prinee of Denmark (Fellowes), very deep maroon, shaded with crimson, very effective.

R. T. Rawlings (Rawlings), clear yellow, fine form.

Sunbeam (Fellowes), clear buff, with a beautiful outline, good and constant.

T. J. Saltmarsh (Rawlings), yellow, deeply edged with red, fine stout cupped petal.

William Rawlings (Rawlings), crimson-purple, fine.

FANCY DAHLIAS.—The previous remarks made with regard to Show flowers are applicable to the Fancy class with a few exceptions, one of which is that many varieties of Fancies require very spare thinning or disbudding, as the Fancy varieties are very easily made coarse by over-thinning. The tipped varieties in this section are much improved by the flowers being put under a pot for a week previous to the show.

Appended is a list of the best twelve Fancy varieties now in cultivation:—

Mrs. John Downie (Turner), orange, tipped with scarlet; a large flower, of fine form and perfect centre.

Charles Wyatt (Keynes), deep rose, flaked with crimson, fine.

Frank Pearce (Rawlings), rose, striped crimson, fine form, constant.

George Barnes (Keynes), lilac, striped crimson, a fine flower.

Henry Eckford (Rawlings), yellow or light buff striped with scarlet.

Henry Glascock (Keynes), buff, crimson stripe, fine.

John Forbes (Keynes), fawn, striped with maroon, fine.

Mrs. N. Halls (Rawlings), bright scarlet, tipped with white, good form.

Mrs. Saunders (Turner), yellow, tipped with white, fine form, very constant, good habit.

Peacock (Turner), dark purple-maroon, distinctly tipped with white.

Rebecca (Keynes), lilac, striped with crimson, large; very constant.

Rev. J. B. M. Camm (Keynes), yellow, flaked red, very large.

CULTIVATION OF THE SHOW DAHLIA.

[By Mr. J. T. West.]

I do not attempt to tell the trade growers anything but what they are fully conversant with already. The purpose of this paper is to throw out a few practical suggestions for criticism that may ultimately benefit some of my brother amateurs; also to incite others to take up the culture of the Dahlia. I do not propose touching upon the propagation of the Dahlia, as I consider that to be of secondary importance, as probably most amateur cultivators depend upon the trade grower to supply plants in the spring. I will further add that I will give my own experience in growing for exhibition, which, of course, is of a very limited character.

In the cultivation of the Show Dahlia the first thing is to make up one's mind not to be baffled by the many obstacles that stand in the way ere success is attained. Probably no florist's flower has more enemies than the Dahlia, nor requires more constant attention. Let none think that Dahlia growing is merely a hobby that can be attended by merely a casual glance round at the plants. It means hard work and worry day and night, and unless this is done no success will be achieved, and the flower will be given up in disgust. On the other hand, no flower pays more liberally for proper attention and care than this flower. In the first place, let those who propose growing the Show Dahlia in the future make up their minds as to the number they are likely to grow, so that they can prepare the ground during the winter months by deep trenching and digging in plenty of manure. Let the soil be laid up in a rough state, so that the frosts, rains, and snows may pulverise and fertilise, and help to keep the vermin down. This I consider far better than to begin in April or May, as if suddenly remembering there is such a flower as the Dahlia, and commencing then to dig and manure to a great extent. Really, in my opinion, this is courting failure. Though the Dahlia is a great feeder, I do not consider it wise to give a lot of manure for it to come into contact with, as that has a great tendency to make the plant grow rank, and throw coarse and rough blooms, thus spoiling all chance of success. The plan I follow is, after the autumn digging, and some time before planting, to dig out holes for each plant, and put in say half a peck of good old rotten manure, thoroughly mixed with the soil. This I find sufficient to give the plant a good start, and to support it until it commences to flower.

If a grower does not grow his own plants it is best to give his orders in to the trade as early as possible, so as to insure sufficient of the sorts required, for many sorts are shy, consequently the stock of the best is soon sold. Early in May the plants will be dispatched to their various destinations; probably little sturdy specimens in thumb pots. When received put into a warm frame or house for a few days until they are rooted well, then transfer into 5 or 7-inch pots in good loam and dung with a little sharp sand. Replace them in the frame or house until they are growing; then admit plenty of air to keep them sturdy and strong and to prevent them drawing up, which is very undesirable at any time. By the end of May the lights can be drawn off all day and put on again at night, with air at the back, until two or three days before planting out, when the lights can be removed entirely.

The first week in June is a good time to put the plants out in the ground or in the holes prepared for them, taking care that the ground is not too wet, or it is likely to give the plants a check and to cake round the roots. A good distance, where one has plenty of room, is 6 feet from row to row and 5 feet from plant to plant in the rows. Of course, all are not so favoured as to have so much room, but it pays in the long run, for the plants grow stronger and more robust; besides that, it is more convenient to get amongst them, especially when the weather is wet. But we cannot draw a hard line in distance of planting, but must go according to the room at our disposal. When they are planted plant some Lettuces between them; these will act as a decoy for slugs, they will eat them instead of the Dahlias. What they leave will come in for the table, as they are sure to be crisp and good. It is also advisable to put a little lime or soot round each plant, as prevention is better than cure.

In a few days they will commence growing, and will want their

stakes, which should be as strong and neat as possible, taking care to give long stakes to the tall growers, and *vice versa*. As the staking proceeds have some raffia ready to tie the plants to the stakes, also a basket filled with small pots, with a little moss or hay inside, so that they can be put upon the top of the stakes as a trap for earwigs. The pots should be taken off every morning or evening to see if there are any earwigs lurking inside the moss. Have a piece of stick in the hand, and kill all intruders. This is the quickest and most effective way; better, I think, than shaking them out, as many escape by that method. The course above recommended has its disadvantages, for the earwigs smell very unpleasantly; but still the Dahlia grower is not as a rule very fastidious so long as his plants are doing well. While I am speaking of insect plagues I might as well mention that if the weather is very dry the black fly often makes its appearance at the end of June or early in July. This is a sad scourge, and taxes our patience as much as anything. Syringing of an evening with tobacco water or quassia is a good plan, also dusting the affected plants with snuff or tobacco powder; either will certainly act as a check upon them.

By the middle of July it will be necessary to thin some of their branches, as too much growth prevents the production of fine flowers. This operation must be regulated by the nature of the variety; some are apt to come large and coarse, from such we must cut away very little, or perhaps not any. The smaller varieties must be cut somewhat severely. When this is done, put side stakes to the plants, one to each branch, to prevent wind breaking them. I find four side stakes and one centre generally sufficient. A good mulching of dung, straw, or anything that will prevent the evaporation of the moisture that is now necessary to the Dahlia must be given before the plants get too large. This plan is also useful for another reason; that you can walk upon the ground better, as it will not pick up so, or cling to the feet to convey loose soil to the paths, which it would do after a heavy rain or watering, for now the plants will want plenty of water; hard-eyed flowers, such as George Rawlings or Prince Bismarck, will want an extra supply.

Many varieties will begin to show their buds; these must be picked off, unless wanted for very early shows. These early blooms weaken the plants, and are mostly poor, even if left on. Early Dahlia blooms are really not wanted in the garden, for they are badly shaped, and with nothing special in colour to recommend them. This remark refers to Show varieties only, not to Cactus or Pompon Dahlias. If the centre buds are picked off the side branches will soon begin to show buds. These can be left, and as soon as they grow as large as a pea, can be thinned to one on a branch, or rather sub-branches, for the plants by this time will have broken into perhaps ten or twelve branches, and you may have one bud to each. In many varieties perhaps the plant had better be thinned to six or eight branches to get the blooms fit for the exhibition table. Such varieties as Bendigo and King of the Purples may be cited in illustration; while varieties like T. J. Saltmarsh, John Standish, or Mrs. Langtry, may be allowed to carry twelve or more. Many amateurs find a difficulty to know what buds to leave in thinning, but I have found from the time the bud first shows itself to the time it is ready for cutting, a month is just sufficient. I find sprinkling with a rose-can very helpful after a hot drying day, as it assists the plants to recover the loss they have sustained during the day.

When the florets of the buds are beginning to show the earwigs begin their depredations in earnest. What is more trying than to find of a morning promising buds spoilt by being gnawed all round the edges by these pests? A piece of wadding tied loosely round the stalk of the buds will be a great check, also liquid indiarubber put on the stalks of the buds; this, however, is rather dangerous if used too freely, for the sun sometimes heats the rubber, and burns through part of the stalk. But then any remedy must be tried. Many place the buds in bags made of muslin, but I do not particularly like them, as they often cause the florets to crowd one another when they are fully out. The best flowers are those which have come out in the natural way with the softening influence of the dews, and no check to interfere with Nature's plan of perfecting beauty. The grower must make up his mind to lose many buds under any circumstances.

About twelve or fourteen days before the Show it will be advisable to "pot" up a few buds—that is, place an inverted 32-size pot over them; this is done by having a stake put in the ground, and a piece of wood a little larger than the pot, with a slit in it for the stalk of the bud, the wood to be lifted up to the height of the bud, and then made secure to the stake. The pot will get warm by the sun's rays, and will be a little forcing house for the bud. Take care to stop all crevices, as the earwigs will otherwise think the pots are put there for their benefit. Should the buds look as though they will be too forward after four or five days take the next forward buds, and do as in the former case; but be very careful over those that have been taken out of the pots, as with care many will be very useful. Put some wadding round them, and shade or otherwise try and keep them. In selecting the buds choose always those with little pin-holes in them, as they always make the best blooms. There is one thing putting buds under pots will do—that is, it will make light flowers purer in colour, also tips more distinct; for instance, Mrs. Gladstone will come nearly white, and such as Mrs. Saunders clear and cleanly tipped.

As the flowers begin to come out, it will be often necessary to cover with shades worked on the same system as the boards for potting the buds. This will retard the flowers, and also protect them from damage by sun and drying winds. Take care the flowers are made secure, otherwise they will chafe. By no means let the plant suffer for water, as now it will require a lot; perhaps a weak stimulant will be required

for some sorts. But if the plants have been well looked after in their earlier stages they will do without it. Stimulants at this period often excite the plants, and cause them to throw out unshapely petals, or perhaps even to cast them all. There will not be much peace for the grower, as the blooms will require constant attention by night and day, as caterpillars and other insects will soon ravage them. Take a lantern out at night and there will be seen earwigs and other marauders busily engaged in undoing what has been done.

The morning before the show it will be wise to examine the blooms, and if there are any doubtful ones not likely to stand the full time, cut them and put in a cool and dark place without water. By this procedure many valuable blooms will be saved. Never cut when the bloom are soft, as I think they shrink up when the sun is out. Cut early in the morning or late at night, when they are stiff and fresh. It is surprising how they will open after a heavy shower or heavy dew. When cutting have tubes, eorks, and boxes all ready, so that they can be put right away without a lot of handling, as they do not improve by being pulled about. But it is needless for me to go any further, as the grower is quite conversant how to cut and stage them. I have given briefly my experiences in these few remarks, trusting they may benefit some one or more, and interest them to grow the noble Queen of Autumn, for which we are all grateful to the Marchioness of Bute for introducing 100 years ago. Let all those who would like to show their gratitude liberally subscribe to our National Society, so that the grand old flower may be still further improved and kept full in view of the British public.

POMPON, SINGLE, AND DECORATIVE DAHLIAS.

[By Joseph Cheal, Crawley, Sussex.]

POMPON OR BOUQUET.

THIS section resembles the large Show Dahlia in all points with the exception of one—that of size. Circular outline, evenness in petal, with a well-raised centre are the principal points, but the smaller the flower the better. Many of the earlier varieties appear to have been introduced from Germany, but steady progress has been made in improving the strain in this country until many of those now in cultivation are perfect little gems of beauty—small, refined, and of brilliant colours. As garden plants they are such early and abundant bloomers that they form striking objects in beds or borders. The flowers being so small and refined in character they can be used as cut flowers in almost any kind of decoration. A few of the best varieties are the following:—Admiration, Cupid, Darkness, E. F. Jungker, Eli Millard, Favourite, Golden Gem, Grace, Guiding Star, Isabel, Iolanthe, Rosalie, Little Duchess, Little Bobby, Lady Blanche, Gem, Whisper, Little Ethel.

SINGLES.

A correspondent, writing to the "Florists' Register" of 1834, on the properties of the Dahlia, says, "Our former observations on the properties of this all-attractive flower having given great satisfaction, and the opinions of many eminent growers coinciding with them in every particular, it would seem prudent to let well enough alone, and not by detailing too nicely our own notions of perfection to endanger the unanimity of feeling which pervades the fancy as to general principles." I, too, may be running a chance of endangering unanimity of feeling in the next subjects with which I have to deal by detailing too nicely my own notions of perfection. Some of the enthusiastic growers of the old Show varieties consider the re-introduction of the singles as altogether a retrograde movement. Others think that the lightness, freedom, and brilliancy of the singles are more to be desired than the more weighty doubles. Since the double form appeared at the commencement of the century such development and steady progress have taken place that they seem to have attained about the height of perfection. So perfect, indeed so excellently modelled, so superb are they as now grown, that the very perfection became almost painful, and the least flaw or irregularity became perfectly unbearable. To such a degree of excellence have they attained that there was nothing more to strive after or possible to attain; we therefore find growers retracing their steps, and returning to first principles, and setting out anew from the starting point, hence a somewhat sudden reappearance of the single type of Dahlia. From the pretty little Dahlia glabrata, introduced in 1840, and crossed with the Dahlia coccinea subsequently introduced, new forms and bright colours very soon appeared.

About the only old variety that appeared in its original form was Paragon. This was in existence in 1834, and I find it described in the catalogue of "Superb Dahlias," sold by Samuel Apply, of Doncaster, for that year. And strange to say, Paragon still holds a place amongst the twenty best varieties for exhibition. The brilliancy and variety of colour and form in the singles is now through hybridisation so great that the cultivator may, be he ever so fastidious, suit his taste and fancy in selecting from them his particular favourites. But there are certain very distinct types and forms to be desired and sought for, and Nature is here so generous that it is comparatively easy to select desirable strains or plants.

Cultivators very generally discard all flowers of a large size; these usually have a coarse appearance, and almost invariably, from the weight of the bloom, hang their heads and hide what beauty they may possess on the plant, and are, when cut, heavy, unmanageable, and useless for decoration. Therefore, flowers of medium and small size are much to be desired, and particularly those that are borne on erect, stiff stalks. As to form, the flowers should be as circular and even in outline as possible, the petals flat and even, neatly and closely fitting or overlapping each other, and well recurved. A flower of this form not only presents a

pleasing and refined appearance, but it lasts much longer when cut than star-like varieties, or those with separate petals.

Of colours, we have such a wide range that it is not difficult to satisfy the most voracious desires in this direction. In self colours and shadings we have a range from the most brilliant and decided colours to the softest and most delicate tints, with the exception of the one cardinal colour, blue. Now we find increasing numbers of varieties with striped, tipped, flaked, and spotted flowers, many of them being very pretty in the combination of colours, and some of the most decided contrasts being very striking in effect. Attention is also being paid to the selection of specially dwarf varieties, and Mr. Girdlestone, the worthy Secretary of the National Dahlia Society, has already succeeded in raising a very dwarf strain. These consist of plants about 18 inches in height, bearing abundant blossoms of ordinary size, and are likely to be very useful for bedding. Promiscuous seed sowing and raising seedling plants give as a result a great variety of subjects, and an occasional plant may be selected of superior merit; but to obtain really satisfactory results, and to secure advance in any desired direction, it is necessary to be very careful in the selection of seed, and careful and systematic hybridisation must be resorted to with definite aims to insure advance in any definite direction.

In the cultivation of the singles, do not overfeed them. Rich ground and stimulating manures will force them out of character, and produce rank growth and coarse flower. Select poor and heavy land for them, and, when planting, give them only sufficient manure close to the roots to give the plant early and rapid growth, and to carry it on to the flowering season. Then an occasional watering is all they require. Give them, in fact, the very opposite treatment to the doubles, or, in a word, feed the doubles, but starve the singles. In cutting single Dahlias always cut the flowers as young as possible, even before they are fully open. If cut thus young, and in the cool of the morning or evening, they will last for a long time. I name as a few of the best varieties in their sections:—Selfs (shaded varieties).—Albert Victor, Cetewayo, Formosa, Amos Perry, Henry Irving, Miss Linnaker, Queen of Singles, Duchess of Westminster, Alba Perfecta, W. C. Harvey, Hugo, Miss Roberts. Margined petals.—Duchess of Albany, Lady Montefiore, Victoria, Beauty of Uplands, Excelsior, James Kelway, Maude Millet, and Mrs. Conninck. Spotted, flaked, and striped.—James Scobie, Mrs. Kennett, Chrs. Laws, Scotch Lassie, and Mr. Rose.

DECORATIVE AND CACTUS DAHLIAS.

In this section we have again a new departure. The true Cactus Dahlia, Juarezi, was imported direct from Mexico. I say true Cactus advisedly, because it is about the only variety that has the narrow-pointed petal, and the whole form of the flower so nearly representing a Cactus. But this variety, with its brilliant hue and unique form, is such a decided acquisition, that it has proved the pioneer of a distinct class that now occupies a very useful position, and it has opened up a new field of enterprise to the devotees of the queen of autumn flowers. All flowers that show a tendency to the free, open, and Cactus like character of this class are eagerly sought after. The field in this direction is still open before us, and we shall doubtless see steady progress in the development of this section. What could be prettier or more useful than a good collection of Pompon Cactus, of decided colours, and miniature in size? A few of the best varieties already raised are Beauty of Brentwood, Panthea, Wm. Rayner, Charming Bride, Empress of India, Juarezi, Lady Marsham, Mrs. Hawkins, Henry Patrick, Mr. Tait, Zulu, and Lady E. Dyke.

EVENTS OF THE WEEK.—To-day (Thursday) the National Chrysanthemum Society's Show will be continued at the Royal Aquarium; also Exhibitions at Brighton, Derby, Edinburgh, and Newcastle-on-Tyne, the latter being continued on Friday. Committee meetings of the Royal Horticultural Society will be held on Tuesday, September 17th. There will be the usual auction sales at Protheroe & Morris's and Stevens's rooms.

— **THE WEATHER IN AUGUST.**—This month was changeable and wet up to the 26th, fine and bright after until the end; only one clear day and eleven bright ones during the month. Rain fell on nineteen days, total 2.92 inches. The greatest amount in twenty-four hours was 0.42 on 19th. Barometer was very changeable. Highest 30.28 at 9 P.M. on 31st, lowest 22.19 at 9 A.M. on 20th. Highest shade temperature 81° on 1st and 30th, lowest 41° on 25th. Lowest on grass 36° on 25th. Wind in a westerly direction on twenty-nine days. Garden spring running 25 gallons per minute on 31st. Harvest operations much delayed by the wet weather.—W. H. DIVERS, *Ketton Hall, Stamford.*

— **THE VEGETABLE CONFERENCE AT CHISWICK** to be held on September 24th, 25th, 26th, progresses in a promising manner, and, as might be expected, many interesting questions have arisen to demand consideration by the Executive Committee. Amongst these is one that is perhaps of primary importance. Intending exhibitors, in a few instances, desire to present collections, and to keep these intact as such. The Committee have determined that the printed schedule must be strictly followed, for in the first place this is not a competitive affair—there is, in fact, no ostensible competition—and the work of the Committees of Selection cannot be efficiently performed unless the subjects submitted are grouped in classes required by the schedule. And this is a simple matter enough, and the schedule is as definite as can be desired. For this important work of selection six Committees of the most experienced cultivators have been arranged, each of these Committees comprising men familiar with the subjects they are appointed to operate upon, both as to nomenclature and the selection of typical examples. A large Committee of Referees will supplement the labours of the working Committees, these being held in readiness to settle doubtful points, and to advise generally as the working Committees may desire. The placing of all exhibits in the classes appointed for them is not only necessary to enable the Committees to act, but to render serviceable in the way intended in the primary idea of the Conference, the final awards of certificates for these will be awarded to the subjects, and will notify recognition of purity of types as well as good cultivation, the genuineness of the several "types" and "strains" being a matter of the first importance. All entries should be received by the 21st inst. At the dinner on the evening of the 24th, at which Mr. Harry Veitch will preside, we shall hope to see a great force of horticultural talent, as it is to be in a special sense a "gardeners' dinner." Intending diners would do well to secure tickets early, by application direct to Mr. A. F. Barron at Chiswick.

— **A BEAN SHOW AT BANBURY.**—A somewhat novel exhibition took place in the Market Place, Banbury, on the 5th inst., on the occasion of Mr. Henry Deverill offering special prizes for the best twenty pods of Neal's Ne Plus Ultra Runner Bean. Something like seventy entries were received from different parts of the country, and by consent of the municipal authorities these were arranged in a line of tables in the Market Place. A very fine lot of Beans were staged in the form of long, handsome, fresh, well coloured, and symmetrical pods, and the Judges proceeded to make their awards surrounded by a considerable body of the public, who appeared to be deeply interested in the competition. Eventually the first prize of 20s. was awarded to Mr. J. Hughes, The Gardens, Eydon Hall, Byfield, Northamptonshire; second, 10s., to Mr. Coupland, gardener to Captain Benyon, Neithrop House, Banbury; third, 7s., to Mr. Wingrove, gardener to G. H. Nelson, Esq., M.P., Rousham Park, Oxford; fourth, 5s., to Mr. Nicholls, gardener to C. Gillett, Esq., Wood Green, Banbury. Six other dishes were highly commended.

— **LARGE ONIONS.**—In connection with the above Show Mr. Deverill exhibited a collection of his famous Onions, staging twelve bulbs of Rousham Park, weighing 20 lbs.; twelve of Ailsa Craig, a magnificent new variety, weighing 30 lbs.; twelve of Cocoonut, weighing 20 lbs.; twelve of Wroxton, weighing 15 lbs.; and twelve of Anglo-Spanish, weighing 18 lbs. One bulb of Anglo-Spanish measured 18½ inches in girth, and weighed 2 lbs. 12 ozs. The largest of the twelve Rousham Park was 18 inches in girth, and weighed 1 lb. 13½ ozs. In addition Mr. Deverill had a collection of examples of twenty to thirty varieties of the older varieties of Onions, which, together with the splendid examples above enumerated, it is his intention to send to the Vegetable Conference at Chiswick.

— **ACALYPHA TRICOLOR.**—This is a very useful plant for furnishing in a small state—that is, from 6 to 15 inches high. The foliage colours splendidly when the plants are grown cool and fully exposed to the sun. Young plants during the summer months are better in cold frames than in a heated structure. It will be necessary to remove the plants by the end of the month to a structure where the temperature will not fall below 50°. When good cuttings are rooted singly in small pots, and then placed into 4-inch pots and grown cool, the plants are short-jointed and the lower leaves fall gracefully over the pot and partially hide it from view. The heads of plants that have grown tall may still be rooted, and will be useful in 4 and 5-inch pots if grown on in a temperature of 50° to 55°. When this plant becomes unduly root-bound in small pots it invariably loses its lower leaves. Before this takes place the soil will become one mass of roots if the plants are

liberally supplied with water. Cuttings of young wood root so freely in heat that there is no difficulty in keeping a stock of plants.—B.

— GARDENING APPOINTMENT.—Mr. R. Pool has been appointed head gardener to R. B. Evered, Esq.

— FITTONIAS.—Good quantities of these should be rooted for furnishing during the autumn and winter. Those to be used first may be rooted singly in small pots, and the remainder in pans. When the latter are rooted tie their roots in moss and place them in boxes, filling the space between the balls with leaf soil. The plants can then be lifted out and used without potting them where large vases, the base of screens, &c., have to be filled with plants and edged with dwarf growing kinds.

— A NUMBER of well-grown plants of *ARTOCARPUS CANNONI* in 5 and 6-inch pots are highly ornamental in the stove during the winter months. Unfortunately it is not propagated with the same freedom as *Acalyphas*, and therefore it is rather difficult to prepare plants so that they will have large fully developed leaves hanging over the rim of the pots. So far we have failed to root the growing ends of plants with good foliage attached. Side shoots of young tender wood, however, can be rooted moderately free if inserted in sandy soil and kept close in the propagating box. It is not very serviceable for room decoration, and therefore the plants, when associated amongst others can be used to advantage even if the base is not well furnished with leaves. Cuttings root at almost any period from early spring to autumn. A few young plants grown with a single stem are far more attractive than one or two large plants.—B.

— WAKEFIELD PAXTON SOCIETY.—The following is the programme of meetings for the third quarter, session 1889. Meetings are held at the Society's rooms, Saw Hotel, Westgate, each Saturday evening, commencing at eight o'clock prompt:—Sept. 14th, Opening ceremony of the Paxton Recreation Ground, at three o'clock in the afternoon; Sept. 21st, "A Retrospective Glance at Gardening," Mr. G. Hemming, Doncaster; Sept. 28th, "Cabbage," Mr. J. S. Brown. (Sale of periodicals). Oct. 5th, "The Gardenia," Mr. W. Grix, Leeds; Oct. 12th, "The Germ Theory," Mr. G. H. Crowther, Royal Institution, Truro; Oct. 19th, "Manures and their Application," Part II., Mr. James Keighley, Bradford; Oct. 26th, "A Tour in Ireland," with views by oxy-hydrogen limelight, Mr. G. Webster. (Sale of periodicals). Nov. 2nd, "The Potato," exhibitions of specimens and discussion; Nov. 9th, "Gardening, and some of the Present-day Difficulties," Mr. L. Twigge; Nov. 16th, The Chrysanthemum Exhibition; essay by Mr. W. Daniels, Mirfield; Nov. 23rd, "Our Streets: How they came by their Names," Mr. H. Oxley; Nov. 30th, "A Few Notes on Herbaceous Plants," Mr. S. Hudson, Woolley. (Sale of periodicals).—G. W. FALLAS and T. GARNETT, *Hon. Secretaries*.

— MR. J. MALLENDER sends the following SUMMARY OF METEOROLOGICAL OBSERVATIONS AT HODSOCK PRIORY, WORKSOP, NOTTS, FOR JUNE, JULY, AND AUGUST, 1889. June: Mean temperature of month, 60.1°; mean temperature of the air at 9 A.M., 61.0°; mean temperature of soil at 1 foot deep, 60.6°; total duration of sunshine 206 hours, or 41 per cent. of possible duration; we had two sunless days; total rainfall, 0.58 inch; rain fell on five days; average velocity of wind, 6.3 miles per hour. A fine pleasant month, very similar to June, 1887. Mean temperature higher than any of the last fourteen years. July: Mean temperature of month, 59.1°; mean temperature of the air at 9 A.M., 60.4°; mean temperature of soil 1 foot deep, 60.5°; total duration of sunshine in month 157 hours, or 31 per cent. of possible; we had one sunless day; total rainfall 1.81 inch, rain fell on seventeen days; average velocity of wind, 7.2 miles per hour. A cool and rather showery month, with average sunshine. August: Mean temperature of month, 58.7°; mean temperature of the air at 8 A.M., 59.9°; mean temperature of soil 1 foot deep, 58.9°; total duration of sunshine in month 135 hours, or 30 per cent. of possible; we had three sunless days; total rainfall, 2.93 inches; rain fell on seventeen days; average velocity of wind, 9.0 miles per hour; velocity exceeded 400 miles on one day. A dull, cool, and showery month except the last few days, which were very fine. The fruit crop here fair, except Apples and Peaches, which are quite a failure. A good autumn bloom of Rose, in spite of the mildew, which has been worse than ever this season.

— GLOXINIAS.—Seedlings that have been grown in cold frames during the past two months will now be useful inside. Place the plants in an intermediate house, and they will quickly come into flower. It

will be necessary to protect them from bright sunshine, and weak stimulants may be given them occasionally. Ripen off gradually plants that have ceased flowering.—N. G. L.

WATSONIA ROSEA.

THE genus *Watsonia* in Mr. J. G. Baker's "Systema Iridacearum" is assigned a position between *Lapeyraisia* and *Acidanthera* in the Iris family, and he enumerates thirteen species, with six or seven varieties. Nearly all are natives of the Cape of Good Hope, and succeeding in favourable situations out of doors, but they may also be counted amongst the cool house plants that can be advantageously grown in pots or placed out in beds under glass. *W. rosea*, which has been known to

FIG. 31.—WATSONIA ROSEA.

cultivators since the beginning of the present century, is one of the most attractive species, being of strong growth, with Iris-like foliage and large, round, bright rose-coloured flowers in compact spikes. A good specimen was shown at a meeting of the Royal Horticultural Society on August 27th, when a first-class certificate was awarded to Mr. T. S. Ware.

ABOUT WASPS.

THESE have been unusually abundant this season, and have proved very destructive to the various crops, both indoors and outside. Peaches, Nectarines, Plums, and Cherries have been great attractions for them on the open walls, and in some gardens almost or quite half of the several crops have been devoured by these pests. There is considerable difficulty in warding them off from outdoor trees, as netting

of very fine mesh only when closely nailed to the wall will keep them out, and even then the smallest possible flaw in the material is quickly sought out and taken advantage of, and often after such trouble has been taken it is only on the removal of the netting that the partial or total loss of the crop is revealed to the gardener in charge. In the vinery, too, they sometimes prove very unwelcome, and if measures are not quickly taken with them the Grapes are sure to disappear with alarming rapidity. Scott's wasp destroyer is the best antidote I have ever used for use in vineries, this being applied with a feather or camel's hair pencil to the berries already attacked. One or two applications proved sufficient, for the whole of the wasps forsook the house in apparent disgust, giving no further trouble for the remainder of the season. Bottles partly filled with sweetened beer attract and dispose of large numbers when suspended on the trees or stood on the ground near the ripening fruit. Undoubtedly the best method is destroying the nests, but this cannot be done by all, and many of those who would, have not the time or tact for tracing them. My friend Mr. Gibson, Draycot, Chippenham, is the best at this I know, but it is only by persistent effort. This year over a hundred nests have been destroyed within varying distances from the garden by the use of cyanide of potassium, obtained in granulated powder from the chemist. This deadly substance may be used in a dry state or in liquid, but probably the latter is the more quickly effective. The powder may be dissolved by being placed in an open-mouthed bottle and water added sufficient for covering. A tablespoonful of the liquid poured in the passage to the nest will prove instant death to each wasp that attempts to enter or leave, as may be proved by anyone visiting the spot a few hours after the application. Unless they are exasperated by juvenile interference, the cyanide may be used at any time of the day without fear, as it only requires a moment's delay when once the whereabouts of the nest is known.

It may not be generally known how easy a matter it is to trace wasps to their nest. The gardener, before mentioned, says that by observing the direction they take on leaving a fruit tree laden with their burden for home they are sure when on wing to take a direct course, but it is not known how far they may travel, and it is only persons who have energy and time who are likely to undertake the journey. For an isolated garden in a country district the destroying of a hundred nests is a feat of no mean order, and certainly deserves mention, involving as it does a considerable saving of choice fruit, which would otherwise be destroyed by those greedy pests.—W. STRUGNELL.

CARNATIONS AT EXHIBITIONS.

I THINK that my friend Mr. A. R. Brown rather misses the point I put before your readers; besides, he is in danger of somewhat degrading the Carnation-growing pursuit by insinuating that good Carnations are grown only in respect of obtaining thereby a certain amount of prize money. I want to see lovers of the Carnation growing good flowers—the best they can afford—quite regardless of anything like a mercenary spirit. Therefore it is that I complain that the standard of Carnation blooms seen at not a few country shows is a low and unworthy one. If Carnations are grown solely as exhibition flowers, and with no higher view than that of winning some money at flower shows, then I think Mr. Brown's contention would be a correct one. But it is because the Carnation bloom at many country shows is poor, and down at a dead level of unworthiness, that I was led to pen the few lines I did in reference to this matter. It appears to me that some exhibitors fancy anything will do for the exhibition table so long as it bears the name of Carnation, even though the flowers may be shapeless masses of rough and dull-coloured petals; and judges appear too prone to encourage them in the practice by awarding prizes because the flowers are the best on the exhibition table. I look to our Carnation societies to do something in a missionary point of view to convert country Carnation growers from the error of their ways, and raise them from the level of ignorance into the higher sphere of a better Carnation knowledge. I think it is very likely prizes are kept low because the quality of the blooms placed upon the exhibition table is poor. Let growers set about producing something better—blooms more worthy of the name of Carnations—and I think the framers of schedules will not be slow to encourage and reward their efforts by increasing not only the money prizes, but also by increasing opportunities of exhibiting this beautiful flower. Good varieties are readily obtainable at a comparatively small cost. Seeing this is so, I hope judges will in the time to come raise somewhat in their mind's eye the ideal of the flower to which they award prizes. If they will do this, the work of reformation will have a fitting commencement.—R. DEAN.

EDIBLE FUNGI.—I am pleased to see that "D. G. B." (page 202) bears me out with regard to the prevailing ignorance on this subject. Although he questions the utility of my suggestion as to coloured plates I am not at all dogmatic on the point, but he in his haste to find fault falls into the very common error of neglecting to suggest something better. There were coloured plates of edible fungi in South Kensington Museum some twenty years ago, which, if memory serves me right, a member of the enigmatical majority alluded to by "D. G. B." might have safely taken as a guide. He also says that while I am loud in the praise of Mushrooms I have not a single word of praise for edible fungi. Why, the whole end and aim of the few remarks I made on the subject was with the view of obtaining better information, and my reasons were

principally that, while in this district there is scarcely a Mushroom this season, there are so many toadstools as to be a positive nuisance, in the grounds at all events; and I thought it a pity to see these collected daily and wheeled to the dung heap. At the same time I should be sorry to think that by any contortion of language it could be construed that I said there were fifty different varieties. As to the people north of the Tweed being unable to distinguish between Mushrooms and toadstools, he again errs. They look upon them as worthless, and speak of the whole class of funguses collectively as puddock stools. One of the easiest things in the world is fault-finding; one of the hardest is obtaining information. The question still remains, How is better information to be obtained?—A. C. W.

THE ROSE SEASON OF 1889.

Now that the din of battle is over, the warriors have gone into their winter quarters prepared "to fight another day," and there is a feeling in all connected with Rose showing that one may "rest and be thankful," it is possible to sit down quietly and take a survey of the field, see where the dead are lying, and where the banner floats which tells of victory; and in truth it is a field where reputations are wrecked and others made, and to the lover of the flower there is ever coming up the memory of some pleasant times, happy meetings, and let it be fairly said times of disappointment and depression; but it is well to look at the bright side of things, although we dare not keep out of sight the shadows which sometimes give by their contrasts greater breadth to the lights.

And now as to the season itself. We get so used to writing about exceptional seasons that we wonder if there is ever to be a normal Rose season. One is too hot, another too cold; one is too forward and another too late, and the wishes of Rose growers vary so much according to their localities that it is very difficult at times to come to a right conclusion. We have growers from far Aberdeen and sturdy Down, from canny Yorkshire and soft and luxurious Devon, from the counties where the east wind has its home, or where at any rate it strikes them with unhampered fury, to the soft and relaxing western counties, from the cold midlands and the bright and warm slopes of the southern counties; and the difference of climate, soil, and situation will colour to a certain extent the ardent east grower with promises. And in truth there are two different ways in which we may regard the season, one as to its connection with Rose exhibitions, the other with regard to its presence in the garden. With regard to 1889 as a Rose exhibition season I think we may safely say that it has been acknowledged on all hands to have been a most irritating and disappointing one. There was as fair a promise as could well be. The May frosts which have been so injurious of late years were absent. May was such a month as poets raved about, and redeemed them from the charge of poetic licence we were wont to charge them with when a piercing north-easter froze the very marrow of our bones. But the May of 1889 was a treat, and under its genial influence Roses grew rapidly, formed their buds, and gave promise of great beauty. There was a check at Whitsuntide, but still the Roses went on; and indeed in some places at such an express speed that before the exhibition time they had in many places passed their best. Thus at the great Show of the National Society at the Crystal Palace, July 6th, the Rose growers of East Anglia, Reigate, and Devon were almost out of the field altogether. Mr. Baker, who won the challenge trophy last year, could not show at all. Mr. T. B. Haywood, who won it in 1884, was pretty well over, and could not exhibit in the large class. The Roses from Suffolk and Norfolk, which have always formed a conspicuous feature of the Show, were almost altogether absent, and thus a very material difference took place in the number of prizes gained by the same persons in the past year compared with the last; and not only did the season make a difference, but the quitting of the field by several who have occupied a distinguished position in it has made a very serious difference, a difference that will be still further accentuated another season.

Two of our very best northern exhibitors, Messrs. T. B. Hall and E. R. Whitwell, have entirely given up exhibiting. It is not to be wondered at when an exhibitor has been successful, when he has gained the "blue riband" of the Rose world, and has had ten years of hard work (for exhibiting is hard work). It is no wonder if, like Mr. Hall, he desires to rest on his laurels; and then sometimes fancy changes, and Orchids usurp the place the Rose once held. The gap thus made will be still further increased by the retirement of Mr. W. J. Grant of Ledbury, another of our most successful exhibitors, and who perhaps never showed in better form than he did in this his last season for exhibiting. It will be readily seen what a difference these things must make. Are there others to occupy their places? I hope so. Mr. E. B. Lindell has come very much to the front this season, has exhibited in good form this year, and I quite expect to see him take a very foremost place.

But to return to the Roses. I hear every year, especially by those whose Roses are not up to the mark, that it is a bad year for Roses, not nearly so good as last year, &c. Now, my own conviction is that Roses were never better, although they came "uncommon awkward" for shows. It was a season (which rarely happens) when light and dark Roses were good; Charles Lefebvre, Camille de Rohan, and other dark Roses were not burnt up; Monsieur Noman, Madame Lacharme, and other light Roses not glued together, and hence when they were brought to the exhibition table they were all in good character. There was never a doubt as to what a Rose was, except when they were dressed (of which more anon), and it was a pleasure to go through box after box and to see how true to character they were. They may have been small or a little too far blown, but there was the Rose unmistakably before you.

It was, however, a season in which the northern growers had the pull, and the southerners showed under difficult circumstances. As a consequence of this the two challenge trophies again went to Messrs. Harkness & Son, whose record this year has been a very remarkable one, while in the case of the amateurs no northern grower was able at the provincial show to wrest the victory from the Essex champion, the Rev. J. H. Pemberton; and at the Crystal Palace Mr. W. J. Grant secured the victory, no more southern growers being able to compete with him—in fact, there the competition was by no means keen. Mr. Pemberton all through the season has shown well, and is an instance of the truth that if anyone wishes to keep up the competition during the season he must grow maiden plants. Most amateurs depend on "cut-backs," and the consequence is that as they are generally early when they are over, so is the chance of anyone who relies on them of getting a prize; but the maidens are late, and take up the place vacated by the former. The names of those who depend on them gradually fall out of the list, but the growers of maidens can keep on to the end. Mr. Pemberton or Mr. Grant can show at Bath during the first days of July, and even earlier, and they can put in an appearance in good form at Wirral or Tibshelf.

There is one subject to which I have already alluded which will become, I am sure, a burning question, and concerning which some decision will have to be made. I have already alluded to it, but it deserves very serious consideration, I mean that of dressing Roses. It was, we thought, one of the charms of the Rose that it needed no extraneous aid. A great outcry was made some years ago because exhibitors used gum in setting up his Roses, a practice which has long prevailed with regard to Pelargoniums, and it was decidedly condemned on the ground that the Rose needed nothing of the kind, and that the only addition was to be a support, so that the bloom might be well seen. There were, indeed, occasionally to be noted exhibitors with a pair of ivory tweezers arranging a petal, but this was thought, I believe, to be a piece of over-carefulness, and might have been left alone; but latterly there has been seen in some quarters a system of dressing which entirely alters the character of the Rose and makes it almost unrecognisable. This is a consummation which was never contemplated, and for which no rules were framed, but I think the National must put its foot down, or the practice will become general; for when it is seen that those who resort to this practice come off victorious, competitors will naturally lay it to the presence of these dressed flowers, although they have really made no appreciable value in winning the prize. Of course the difficulty will be in determining what is a dressed and what an undressed Rose; still, it is one of those nettles which must be fairly grasped. One great charm of the Rose is that it has so many different types of form, and if efforts be made to reduce them all to one uniform style a great deal of their charm would be taken away. I may be a heretic, but I greatly prefer the form of Marie Baumann to that of A. K. Williams, which however, seems to be the ideal of those who go in for dressed flowers.

One thing was, I think, very noticeable at exhibitions this year—viz., the manner in which some old Roses vindicated themselves, and were seen in great beauty. How lovely were Comte Raimbaud, Horace Vernet, Charles Lefebvre, and such Roses as Mons. Noman, Her Majesty (Simkins), Marie Finger, Captain Christy, and many others; indeed, there are some whose names had been well nigh forgotten, who showed that they were still to be reckoned with, while of new Roses some gained and others lost in reputation. Thus we cannot too highly praise the lovely bloom of Victor Hugo shown by Mr. Pemberton at Sheffield, or those of Sir Rowland Hill by Mr. Mack. Earl of Dufferin has established its reputation as a grand exhibition Rose, and Caroline d'Arden made an advance, while Grand Mogul has been regarded as indistinct. It appears to me to be Jean Soupert over again, colour, form, and foliage exactly similar to it. I think that the Rose which has most gained in favour is Rosieriste Jacobs. Everywhere it has been shown well, in some cases has been regarded as the best H.P. in the show; and thus a Rose which has been in commerce for nine years, for it was let out by the Widow Ducher in 1880, comes to the front; it was included in the supplement of the National Rose Society, and evidently deserves its place there.

Tea Roses have again been well exhibited, and some good new varieties have been shown. I do not think that anyone who saw Mr. Geo. Paul's bloom of L'Ideale will hesitate to say that in it we have a

most charming buttonhole Rose, with tints which it is almost impossible to describe, but which will make the ladies call it "a love." Souvenir de Sarah A. Prince has been variously judged, but I believe that the general verdict is that it is a great acquisition in white Tea-scented Roses; it is hardly fair to judge from a first season. The demand for it has been so great that Mr. Prince has been forced to work it as hard as he can, and as a result blooms have been cut from plants which had already done their duty in producing wood, but it has occasionally been so shown by Mr. Prince as to warrant one in saying that it is a great acquisition. It has not the pointed bud of Niphetos, but neither does it sprawl about as does that flower; the white is very pure, and it is very fragrant. Madame Hoste has been well shown more than once. It is a fine, bold, upright flower, and should it have enough stuff in it will be a most valuable Rose both for the garden and exhibition; it, too, may have suffered from over-propagation, and may be much improved in this respect when stronger plants are grown. Ernest Metz.—I have seen but one bloom of this flower kindly sent to me by my friend Mr. B. Cant. It has a grand stout footstalk, and the flowers are produced to all appearance singly. In colour the bloom I saw approached very closely to Catherine Mermet, but that is not the description which I have seen of it in Ketton's catalogue, where it is described of a delicate carmine rose with deeper centre, and Mr. Burrell informs me that he has had a bloom of it which displays the coppery rose colour of Comtesse Riza du Parc, and if so a Rose of that colour that does not quarter will be a very great gain. Pierre Guillot is another beautiful Rose of Guillot's of the Madame de Watteville type. I have not seen it, but Mr. Burrell informs me that it is given to quartering. Lady Castlereagh, another of the Irish seedlings, promises to be a valuable addition. I have had a few blooms of it, and they were very charming in colour, of good shape, plenty of petals, and opening freely; the colour a soft yellowish Rose, deeper on the margin of the petals.

I think no member of the National Rose Society, in looking on the Shows of 1889, but will feel that the Society was the victim of unfortunate circumstances. Can one ever forget the heat, the crush, the inconvenience of that tent at the Crystal Palace, all owing to the perverseness of that Eastern potentate, whom we at any rate would have wished had remained in his far off land? Never were fair hopes so falsified. Our Royal Patroness had announced her intention of coming to the Show early in the day, when she would have a good opportunity of seeing the flowers in their beauty; but the Shah would come, and would fix no other day, and so perforce the Crystal Palace Company had to submit, and at considerable expense put up the tent instead of having the Show in the Palace itself, and H.R.H. the Princess of Wales only looked upon faded and miserable flowers. I have heard from some loud condemnations of the Crystal Palace Company, but they are undeserved; it was a great loss to them, for as the Shah was bound to come there some day, it was rolling the attractions of two days into one. Mr. Head, the garden superintendent, had to work under great difficulties, and I do not think I ever saw anyone more thoroughly done for than he was that day. Well, the Shah does not often come, and we of this generation shall never again be put out by His Oriental Majesty. Sheffield, too, was not what the Society would have wished to see, the unfavourable character of the weather preceding and on the day of Show militated greatly against its success.

Again I have to express my thanks to so many kind friends with whom my annual duties have brought me into contact, and it is no slight matter of thankfulness that I have been able to fulfil all my engagements which the cooler weather made this year more pleasant than usual; no dusty and hot journeys, and save at the Palace no hot and stifling tents. I have said little about the home enjoyment of Roses; this I may touch upon at some future time.—D., Deal.

GRAND MOGUL AND JEAN SOUPERT.

I STILL think these Roses are practically identical. Having had a dozen plants of each growing close together for two years, I have been able to compare them constantly in all stages, and find them alike in every respect. The similarity is the more striking, because Jean Soupert the elder was so very distinct, when it came out, from other H.P.'s in every characteristic. The manner of growth, appearance of the wood, shape of the bud, the aggravating way in which, when the bud is formed, the plant seems to put all its strength into thickening the base of the shoot instead of swelling the bud, the colour and shape of the flower, were all unique till Grand Mogul appeared on the scene, and in no single particular can I detect any difference. It would, of course, be possible to select specimens of each which would be somewhat dissimilar, but there is hardly a variety in which some temporary variations might not be found, especially at this time of year. I think I could now cut a white Comtesse de Serenye and a pinkish Madame Lacharme; while among Teas I noticed to-day one or two Catherine Mermets nearly as white as The Bride, and a Madame Lambard quite as yellow as red. Wood, leaves, and thorns are a surer test. I can only say that I cannot find the differences noted in last week's Journal. It is true that a well-known exhibitor has written me that he finds one of the two a better bloom than the other, but with me there has been, as far as I can judge, the same average, both of quantity and quality, in each. If Grand Mogul be a seedling from A. K. Williams, a Rose of later date than Jean Soupert, it is certainly a wonderful thing that they should be so

similar, and both run in such a distinct and unusual groove ; but, if not actually identical, they are surely "too much alike" to be reckoned as separate by the N.R.S. A trained eye would generally, I think, be able to identify Sir Garnet Wolseley apart from Ferdinand de Lesseps as being less dark, if both are grown to perfection, but I have not heard much fault found with the verdict that these two are too much alike to be exhibited in the same stand.—W. R. RAILLEM.

ROYAL HORTICULTURAL SOCIETY.

SEPTEMBER 5TH.

FLORAL COMMITTEE.—A meeting of this Committee was held in the Gardens at Chiswick on Thursday last, September 5th, when Messrs. W. Marshall, Shirley Hibberd, F. Ross, and Lewis Castle were present. The collections of Heliotropes, Ageratums, Pelargoniums, Asters, and Dahlias were inspected, and awards were made for the following, three marks being equivalent to a first-class certificate, and two indicating an award of merit.

ASTERS.

These constitute a fine display, a large space of ground being occupied with them, the trials of strains and varieties being numerous and thoroughly representative. Certificates were awarded for Hedgehog, Imbricated Pompon, Half Dwarf Pompon, Victoria, New Liliput, Victoria Needle, Cocardeau or Crown, Dwarf Pyramidal, Large flowered Dwarf Queen, and Improved Rose. Awards of merit were granted for Dwarf Chrysanthemum, Dwarf Queen Victoria, Dwarf Bouquet, and New Victoria (Barr), most of those named being grown from seed supplied by Messrs. Putz and Dippe respectively.

AFRICAN MARIGOLDS.

Certificates were awarded for the following :—

Prince of Orange.—A compact growing variety, 2 feet high, large well formed, richly coloured flowers.

Lemon Queen.—Similar height to the above, very even, flowers good shape, soft clear lemon tint.

Dwarf Orange.—About 20 inches high, and would probably be less in an open situation, good habit, flowers, and colour.

Dwarf Golden.—Compact, free, and useful variety.

FRENCH MARIGOLDS.

Electric Light.—Dwarf, free, and good, flowers pale lemon.

Dobbie's French Selected.—Tall, flowers yellow with a few stripes, excellent shape, awarded a certificate for its floral quality.

DAHLIAS.

A large number of Dahlias came under notice, and certificates were awarded for the undermentioned.

Single.—Florrie Fisher (Ware), Chilwell Beauty (Ware), Miss L. Pryor (Ware), Kate (Ware), Paragon (Turner), Amos Perry (Turner), Mr. Kennett (Turner), Fashion (Cheal), Victory (Cheal), Magpie (Cheal), and Mrs. Kennett (Cheal). Awards of merit were adjudged for Duchess of Westminster (Ware), Miss Gordon (Turner), Guardsman (Turner), Hugo (Cheal), Negro (Cheal), and Edith (Cheal).

A certificate was also awarded for Empress of India (Turner), a crimson Cactus Dahlia ; and awards of merit for Professor Baldwin (Ware), a scarlet Cactus Dahlia, and North Light (Turner), a brilliant scarlet Pompon.

HELIOTROPES.

First-class certificates were adjudged for the following :—

Capus (Lemoine).—A remarkable variety with deep purple flowers, large truss, and good habit.

Fleur d'Été (Lemoine).—Light colour, large flowers and truss, dwarf compact habit ; free, and useful.

Victor Durny (Lemoine).—A tall, strong-growing variety, having an enormous truss of purplish flowers. Effective and useful for training against a wall.

ZONAL PELARGONIUMS.

Souvenir de Mirande (Lemoine).—Single, white centre, cerise edge, finely formed flower and truss, very distinct.

Opal (Pearson).—Single, dark salmon, darker centre, fine bold flower, good habit, free.

Charbon Ardent (Lemoine).—Double, brilliant orange scarlet, a dazzling, and distinct shade.

Seedling 137 (Lemoine).—Single, very large truss, of a peculiar rosy tint.

Semis (Lemoine).—Purplish crimson, rich colour, large semi-globular truss, one of the Nosegay type (award of merit).

SCABIOUS.

Half Dwarf Blood Red (Vilmorin).—An excellent strain, of an intensely light yet rich crimson colour. Fine compact habit.

A capital strain of Zinnias (Putz) was also commended.

CALADIUMS.—When these show signs of going to rest water should be gradually withheld until the foliage dies away in an almost natural manner. They should not be placed in a lower temperature than 60°. The tubers frequently rot when the plants are removed to a cool

structure and dried off prematurely. Treat Achimenes that have done flowering in the same way where the tubers are required for yielding plants another year.—N.

NATIONAL CHRYSANTHEMUM SOCIETY.

SEPTEMBER 11TH AND 12TH.

THE above Society's early Show was held in the Royal Aquarium, Westminster, on Wednesday and Thursday, when a large number of exhibitors competed, but chiefly in the Dahlia classes.

For a group of Chrysanthemums in pots arranged in a space of 60 square feet, quality and effect to be the features considered, Messrs. J. Laing & Sons, Forest Hill, were first, showing a tasteful collection similar to that at the Crystal Palace on the previous Friday. Mr. J. Chard, Brunswick Nursery, Stoke Newington, was a close second, a notable variety in his group being a quilled sport from Madame C. Desgrange named Mrs. Chard. Mr. G. Stevens, St. John's Nursery, Putney, was third for a group of taller plants edged with yellow and bronze Pommpons.

In the class for a collection of cut Chrysanthemum blooms Mr. Robert Owen, Maidenhead, secured first honours for over forty bunches of flowers, representing nearly as many varieties. The best were Mrs. Cullingford, white ; Frederick Pelé, red ; Madame Desgrange, white ; G. Wermig, yellow ; Mrs. J. R. Pitcher, white, slight blush tint ; Surprise, small rosy Pompon ; Mr. W. Piercy, bronzy red ; Canari, small yellow Pompon ; and St. Crouts, pink. Messrs. J. Laing & Sons were placed second for a bright and effective collection. Mr. E. F. Such, Maidenhead, was third with smaller bunches and flowers.

Five stands of twelve blooms of Madame C. Desgrange were shown, Mr. J. Blackburne, gardener to J. Scott, jun., Esq., Elmstead Grange, Chislehurst, was first for grand blooms, 6 and 7 inches in diameter, pure and substantial. Mr. J. Hudd, gardener to F. W. Prior, Esq., Gordon House, Blackheath Park, was a good second, and Mr. J. Barker, gardener to G. Taylor, Esq., Burton Closes, Bakewell, was third. Eight exhibits of six bunches of the same variety were entered, Mr. J. Blackburne leading, followed by Messrs. Pratt and Hudd.

A magnificent stand of twelve blooms of G. Wermig won Mr. Blackburne the premier prize in its class, the blooms being equally meritorious with the same exhibitor's Madame Desgrange. Of five stands of six bunches of G. Wermig Mr. H. Neary, gardener to the Rev. R. W. Powell, Holy Innocents, Hornsey, had the best ; Mr. Wright, Middle Temple Gardens, being second ; and Mr. H. Shoemith, gardener to M. Hodgson, Esq., Shirley Cottage, Croydon, third.

With twelve Pommpons Mr. D. B. Crane, 4, Woodview Terrace, Archway Road, Highgate, won first honours for excellent blooms of Lyon, Mrs. Cullingford, Blushing Bride, Précocité, Miss Davis, Alice Butcher, and Piercy's Seedling. Messrs. Neary and G. Stevens were second and third respectively.

For twelve bunches of Chrysanthemums Mr. D. B. Crane was the most successful exhibitor, showing good blooms of Sam Henshaw, G. Wermig, Madame C. Desgrange, Bronze Felicity, and Feu de Bengale. Mr. A. R. Rendell, 26, Northwood Road, Archway Road, Highgate, was second.

The Dahlias were numerous in all the classes, but as the exhibitors and the varieties were practically the same as those at the Crystal Palace in the previous week, it is not necessary to repeat them.

A meeting of the Floral Committee was held in St. Stephen's Hall at 12.30 P.M., Mr. E. Sanderson presiding, when certificates were awarded for several new Dahlias and one Chrysanthemum. At 4 P.M. a conference of Chrysanthemum growers was held in the same hall, papers being contributed by Mr. W. Piercy and Mr. J. Doughty, which we are compelled to reserve until next week.

Mr. T. S. Ware, Tottenham, had an extensive and handsome group of Dahlias, for which a silver-gilt medal was awarded. Messrs. H. Cannell & Sons, Swanley, also showed an admirable group of Dahlias, Begonias, Cockscombs, &c. (silver medal). Messrs. J. Laing & Son contributed a collection of Apples (highly commended). Messrs. J. Peed and Sons, Streatham, also had a collection of Apples (commended). and Mr. W. Gordon, Twickenham, had a group of Lilies (silver medal).

A MEETING of the Committee was held at Anderton's Hotel, Fleet Street, on Monday evening, Mr. R. Dean in the chair, there being a good attendance of members. The minutes of the last meeting having been read, the Hon. Secretary, Mr. W. Holmes, reported that the catalogue Sub-Committee were issuing a supplementary catalogue of eight or nine pages, which would be ready for distribution on Wednesday next at a cost of 3d. That the Sub-committee appointed to make arrangements for the celebration of the Centenary of the Chrysanthemum in

1890 had arranged certain preliminaries, and they were in communication with the authorities of the Royal Aquarium, and would shortly make a definite report. Communications have been received from the Auckland and New Zealand Horticultural Society inquiring for terms of affiliation with the N.C.S., thus proving the interest taken in the work of the Society at the Antipodes, and from Launceston, Tasmania, had been received an order for a dozen catalogues of Chrysanthemums issued by the Society. The Hon. Secretary reported that he had admitted the Penzance, Crediton, and Dalston and Haggerstone Chrysanthemum Societies to affiliation during the recess, and his action was approved by the Committee. Twenty-nine new members were elected, including two one-guinea Fellows, bringing the number of members up to 608.

An offer received from Messrs. Restall & Co., Cheapside, Birmingham, for the manufacture of the medals of the Society was considered, and the Hon. Secretary was instructed to obtain a limited number as samples. The consideration of some other matters of detail brought the proceedings to a close.

AGAVES AND YUCCAS.

ACCORDING to a London daily paper of the 30th ult. "the gardens and hothouses at Hamilton Palace are among the most extensive in the kingdom, and possess some very rare specimens of plants and flowers. The grandfather of the present Duke, as was the custom in Scotland among the great magnates in those days, had agents in all parts of the world who from time to time sent rare and beautiful plants to their employer. Hamilton Palace for many years was the only place where the Dalhousiana Rhododendron blossomed in Scotland, and just now a most beautiful specimen of the Yucca gloriosa variegata is in flower in the hothouse. It is said to blossom only once in a hundred years, and is the second plant that has flowered there. The plant stands 14 feet high, and the spike, bearing flowers of a rich creamy white, with a perfume like fresh coffee, is over 2 feet long."

The above paragraph serves to remind readers that there still clings to certain plants the reputation of having qualities that they do not as a matter of fact possess. The American Agave is one of them. The reputed flowering of this plant under cultivation after having attained the age of a hundred years is a tradition that would be difficult to trace to its origin, and more so to determine the extent it is correctly regarded in public opinion as being simply a floricultural fiction. It would, however, appear to be by no means a restricted belief shared only by an unintelligent class of people, notwithstanding the introduction of the plant to this country dates back to 1640, and the variegated form of it an additional forty years. It seems the Agave is no longer to be invested with the monopoly hitherto attributed, perhaps more widely than may be generally imagined, to its most fantastic feature, this being now claimed for one of its own class and order, and possibly there may be fears that there is no knowing where the implications may end. The Yucca gloriosa variegata may not be as generally well known as its prototype, which it may be remembered, like the Agave, hails from America, having a priority of about four years. In the case of the Agave, it was the variegated form that was first introduced, but not so in that of the Yucca, which, as erroneously remarked above, "blossoms only once in a hundred years." Planted in suitable situations out of doors Yuccas are very picturesque objects, and they have been known to flower three or four times in about a quarter of the space of time mentioned in reference to those at Hamilton Palace. Sometimes they produce colossal spikes with innumerable blooms, pleasing in appearance beyond description, and so impressively attractive that the remembrance of them remains until their flowering time recurs again.—J. E. J.

TREATMENT OF SOILS AND MANURES.

IN reply to Mr. Tonks, under the above heading on page 173, I did not pretend to use precise scientific terms, but hoped to make myself understood by the majority. As to the chemical actions and reactions referred to in my article, I am prepared to substantiate them. That most of the ingredients in artificial manures are in a compound form ready to mix with water and be absorbed by the plants I am aware, but of all the manures I have used or tested I never knew any that did not contain free acids. I could name several that are full of free acids, and that is the foundation of my statement. Carbonic dioxide and carbonic acid are not one, but are the same thing in a different form. Carbonic acid, H_2CO_3 , is a composition of hydrogen, carbon, and oxygen, while carbonic dioxide, CO_2 , is, as the name tells us, as di means two, is composed of carbon and oxygen, of oxygen two parts. Carbonic dioxide is a carbonic anhydrous acid. Whether Sachs and Warrington tell us or not that all the carbon is taken in through the pores of the leaves, I do not admit the statements. Carbonic dioxide is one of the heaviest vapours we have, and can be poured from one glass into another. This is one of the wise provisions of Nature, so that the carbonic dioxide of the atmosphere falls to the ground, there to mix with potash, soda, lime, magnesia, and ammonia, forming potassic carbonates, sodic car-

bonates, &c. It is pure assumption for Mr. Tonks to suppose that carbon is taken into the plant in this form and thrown off without being utilised. Will Mr. Tonks tell me where the other half of carbon comes from that he speaks of, and where the carbon comes from to form carbonates, if not from the manure, and where the carbonic acid from manure goes?

If Mr. Tonks had spent as much time on my article as he would have us believe, he would have discerned that I had stated six organic elements to which phosphorus belongs, as well as four inorganic as taking first place as plant foods. Mr. Tonks tries to show that hundreds of thousands of pounds are spent in phosphorus where nothing is spent in potassium, magnesium, calcium, and iron for manure; but as I understand the matter one or more of those elements are combined with phosphorus that is usually bought in this country. As to the division of the soil, I maintain that I am correct. I thought I was clear enough upon the point of the smallness of the soluble inorganic "active" part, and Mr. Tonks confirms me when he states the undecomposed minerals, which, by the united action of cold, heat, carbonic acid, and oxygen, are first disintegrated and then decomposed. Is not this the same process that I mentioned?

I did not say stable manure was very uncertain. I am so sure of its certainty that I should have no hesitation in growing for a wager against artificial manures under similar conditions. Is artificial manure a separate creation? or is it, as I understand, made from the created, and with well-prepared home manure both crops and land improve? If Mr. Tonks had spent as much time in ascertaining whether I was right as he did to prove me wrong, he would have come to a different conclusion than that 1 cwt. of artificial manure is as good as 2 tons of home manure. Why is it that the London growers do not use more artificials and save wear and tear of horses and carts in bringing manure from London? They know there is more body in natural manures, and that they do not impoverish their land. In most private gardens cow and horse dung can be had when a £10 cheque cannot always be obtained for purchasing something else. Before Mr. Tonks tries to persuade gardeners of the superior advantages of artificial manure he ought to act up to my suggestions and test those manures first that are at the disposal of the gardener. Though I have most of the authorities by me, I am not satisfied to always believe all that others tell us, but like to find something out for myself, and write from my own experience. Mr. Tonks, I think, can do more good by teaching what he considers good practice in good English than by quoting Latin mottoes which have nothing to do with either manures or cultivation.—G. A. BISHOP.

CROTONS.

WHERE small highly coloured Crotons in 3-inch pots are appreciated for furnishing with Mosses, Ferns, and other small plants, cuttings should be rooted at once. Plants from which good heads were removed some time ago have yielded quantities of side growths, well coloured, that are very suitable for this purpose. Only well coloured cuttings should be inserted, and when rooted fully exposed to the sun. All plants that are highly coloured and large enough for the purpose for which they are wanted may be ventilated more liberally, and kept cooler to prevent them starting again into fresh growth. Growth made after this date does not always colour satisfactorily, and therefore it is best to prevent it if possible.—B.

CRYSTAL PALACE FRUIT SHOW.

SEPTEMBER 6TH AND 7TH.

THE annual Exhibition of fruits at Sydenham has become one of the most important metropolitan events of the horticultural year, and a thoroughly representative display is invariably provided. The time at which it is held is a convenient one, and usually permits growers to stage fair samples of their produce, while the prizes are sufficiently liberal to induce exhibitors to travel from a distance, thus making the competition keener and conveying a better general idea of garden fruit culture throughout England. All the classes are open, and the prizes range from £12 to 5s., so there is a chance for competitors to clear their expenses and perhaps allow a margin of profit for the labour incurred. Collections of Grapes, Peaches, Nectarines, Plums, and Melons made the chief features, and to these the greater number of the thirty-two classes were devoted, but there was also provision for Figs, Tomatoes, Apples, and Pears. With regard to the two last the date is too early to expect many exhibits, and the autumn Show to be held at the Crystal Palace on October 10th and 12th will probably be the hardy fruit exhibition of the season in London. Yet the Apples staged were in most cases of admirable size and quality, and the number was larger than was anticipated, the non-competing exhibits adding materially to the display. They were not, it is true, all from trees out of doors, and a good proportion of the finest samples were no doubt gathered in orchard houses, which is somewhat misleading to the general public when the fact is not stated on the exhibits.

The quality of the exhibits generally was exceptionally satisfactory, and the number of entries was also good, the whole of the north nave being occupied with the tables devoted to the fruit classes. As is now customary at the Palace, these are arranged with spaces between, so that visitors can readily inspect the display without having to pass all round in a continuous crowd, as was necessary at one time, and Mr. W. G. Head has within recent years greatly improved the system of arrange-

ment in this and other respects. The introduction of foliage plants in lines on the table or in intermediate groups, together with the cut flowers in competition, and the groups of Chrysanthemums, Tuberous Begonias, increased the variety, brightness, and interest of the Show considerably.

COLLECTIONS OF FRUIT.

Three classes were devoted to these, and they always constitute one of the most interesting portions of the Show. The first was that for not less than twenty dishes, in which it was required that four varieties of Grapes (two white and two black, two bunches of each variety), two Pines, two Melons, two dishes of Peaches, two of Nectarines, and two of Plums be shown, the remainder to be distinct. The prizes were £12, £8, and £4, and for these three exhibitors entered, all staging good specimens, but after a close examination the premier award was granted to Mr. H. W. Ward, gardener to Right Hon. the Earl of Radnor, Salisbury, who had admirable samples of the following fruits:—Grapes, Muscat of Alexandria, very large bunches, medium berries; Alnwick Seedling, good colour, irregular bunches; Foster's Seedling, large bunches, well ripened, but dull dark colour; and Gros Maroc, compact bunches, large berries, good colour. Peaches, Sea Eagle, very large, and deep colour; with Goshawk, medium size. Nectarines, Elruge and Pine Apple, well ripened; fine Moorpark Apricots; Guthrie's Late Gage and Transparent Gage Plums; Citrons, Filberts, Raspberries, Red Robin Gooseberries, Brunswick Figs; medium-sized, well-proportioned Smooth Cayenne and Queen Pine Apples, Green Gem and seedling Melons, Williams' Bon Chrétien Pears, Winter Pearmain Apples, richly coloured; Morello Cherries, fine; well-kept White Dutch Currants; St. Michael Oranges, and Mulberries. Mr. J. H. Goodacre, gardener to the Earl of Harrington, Elvaston Castle, Derby, was second, showing Alnwick Seedling, Madresfield Court, and Muscat of Alexandria Grapes, very fine; Queen and Smooth Cayenne Pines were also excellent; and Violette Hâtive, with Rivers' Orange Nectarine were good. Mr. Goodacre scored well in Grapes, and well deserved his position; but there was a little falling off in some of the other dishes, as there almost invariably is in these large collections. Mr. J. McIndoe, gardener to Sir J. W. Pease, Bart., Hutton Hall, Guisborough, was third, his Grapes being extremely fine, especially Gros Colman and Gros Maroc. Plums also were good, and the collection altogether was a creditable one.

The next class was that for a collection to consist of twelve dishes, comprising one dish of black Grapes and one dish of white Grapes (three bunches each), and two Melons, and one dish each of the other varieties. The three prizes offered were £8, £6, and £4 respectively. The competition was excellent in this class, seven exhibitors entering, and the first prize was secured by Mr. R. Parker, gardener to J. Corbett, Esq., M.P., Impney, Droitwich, with an excellent collection, including the varieties named below:—Grapes, Muscat of Alexandria, large even bunches, beautifully coloured, and Alicante, even, bunches and berries with a fine deep bloom; Williams' Bon Chrétien Pear, Worcester Pearmain Apples, Carter's Blenheim Orange, and a seedling Melon, Morello Cherries, Victoria Nectarine, fine; Royal George Peaches, Black Ischia Figs, Kirke's Plum, and a large handsome Smooth Cayenne Pine. Mr. A. Miller, gardener to W. H. Long, Esq., M.P., Rood Ashton Park, Trowbridge, Wilts, was second with capital Alicante and Muscat of Alexandria Grapes, fine Peaches, Nectarines, Figs, and Plums. Mr. T. Coomber, gardener to J. A. Rolls, Esq., The Hendre, Monmouth, was a close third, having fine Grapes, Peaches, Plums, and Cherries.

Still another class was devoted to collections, this time to consist of eight dishes, distinct, Pines excluded. There were three entries, and the most successful exhibitor was Mr. J. Dawes, gardener to M. Bidulph, Esq., Ledbury Park, Ledbury. His collection comprised Muscat of Alexandria Grapes rather green, but fine; Madresfield Court Grapes, excellent colour and even bunches; Dymond Peaches, Pitmaston Orange Nectarines, both fine; Doyenné Boussoch Pears, Jefferson Plums, Golden Perfection Melon, and Black Ischia Figs. Mr. C. J. Goldsmith, Kelsey Manor Gardens, Beckenham, was second, Golden Eagle Peaches being uncommonly handsome, large, and of a rich golden hue, and Mr. R. Ocock, Romford, was third.

GRAPES.

The Grapes formed an important show in themselves, and as twelve classes were specially allotted to them it can be imagined that the exhibits occupied considerable space, particularly since there were six to nine entries in the classes. The competition has been keener on some previous occasions, but there has rarely been a more strongly marked evenness of quality.

For a collection of ten varieties, two bunches each, six competitors entered, Mr. J. H. Goodacre winning first honours with Madresfield Court, small in bunch and berry, but of good colour; Muscat Hamburg, medium sized, compact bunches; Foster's Seedling, clean, even bunches of bright colour; Lady Downe's, long shoulderless bunches, good bloom; Gros Maroc, solid bunches, large berries, and excellent colour; Alnwick Seedling, even bunches, capital colour; Muscat of Alexandria, clean fine colour, large berries; Alicante, heavy bunches, small berries, dense bloom; Black Hamburg, medium size bunches and berries, but well coloured; Mrs. Pince Muscat, wanting in colour. Mr. James Dawes was accorded second honours for capital bunches of Alicante, Alnwick Seedling, Gros Maroc, Madresfield Court, and Muscat of Alexandria. Mr. H. W. Ward was third with clean, even samples, Golden Queen being notable, the others somewhat small.

With five varieties, two bunches of each, Mr. W. Taylor, gardener to J. Chaffin, Esq., Bath, was adjudged the premier position amongst six competitors. He had capital examples of Madresfield Court, large in

bunch and berry; Alicante, excellent colour; Muscat of Alexandria, very large bunches, and rich colour; Alnwick Seedling, enormous berries; and Gros Maroc, medium size, fine bloom. Mr. C. Warden, gardener to S. T. Bathurst, Esq., Clarendon Park, Salisbury, was second with good bunches, but rather small berries; Alicante and Madresfield Court being the most notable; and Mr. T. Osman, gardener to C. J. Baker, Esq., Ottershaw Park, Chertsey, was third with larger bunches, but rather wanting in colour.

Black Hamburg.—In this as in all the specially named variety classes, three bunches were required. Seven exhibitors entered, all showing fairly good specimens. Mr. J. Bury, gardener to C. Bayer, Esq., Tewkesbury Lodge, Forest Hill, won first honours for handsome bunches, the berries large and even; and Mr. J. Gibson, gardener to Earl Cowley, Draycot, Chippenham, was second, his bunches being large but slightly rubbed. Mr. C. Griffin, gardener to Miss Christy, Coombe Bank, Kingston-on-Thames, was third with compact bunches, a little deficient in colour, but good examples of the variety.

Muscat of Alexandria.—Mr. W. Taylor had the best of those shown by four exhibitors. The bunches were large and of capital colour, the berries fine and clear. Mr. C. J. Goldsmith was second with smaller bunches, and Mr. J. W. Reed, Weybridge, was third for rather green samples, but showing good culture.

Gros Maroc.—Five entered with this variety, Mr. J. Hollingworth, gardener to J. F. Campbell, Esq., Woodseat, Utttoxeter, leading with extremely large bunches and fine berries, having a rich bloom. Mr. W. Allan, gardener to Lord Suffield, Gunton Park, Norwich, was second for much smaller bunches but with large berries. Mr. J. Wallis, gardener to R. Sneyd, Esq., Keele Hall, Newcastle, Staffs, was third for medium-sized bunches of good colour.

Madresfield Court.—There was good competition in these classes, nine showing. Mr. J. Gibson was first with large well shaped bunches, bearing a dense bloom. Mr. J. Taverner, gardener to Sir A. K. Macdonald, Bart., Woolmer, Liphook, Hants, was second, his bunches being of medium size but remarkably coloured and one faulty. Mr. J. Bury was third for large bunches and berries not fully coloured.

Alicante.—This was a fine class, the nine competitors all showing well, and the contest was a close one. Mr. W. Taylor ultimately secured first honours for solid heavy bunches with a dense bloom. Mr. J. Hollingworth was second, the bunches of great size but rather crowded, and the berries smaller but very handsome and with a fine bloom. Mr. C. Griffin and Mr. J. T. Wright were equal thirds for heavy bunches of good colour.

Any other Black Variety.—There were nine competitors in this class, and some excellent bunches were staged. Mr. Hookings, West Moulsey, won chief honours with Gros Colman, fine in bunch and berry, the colour and bloom admirable. Mr. J. Bury, Forest Hill, was second with Alnwick Seedling, bunches and berries very large, and the colour good. The third prize bunches were fine examples of Gros Colman from Mr. McIndoe.

Any other White Variety.—The same number entered in this class as in the preceding. Mr. Allan was first with a variety named Foster's Seedling, but quite distinct from the ordinary type, the berries large, somewhat tapering, firmer in the flesh than Foster's, and of a fine golden colour. Mr. Ward followed with large bunches of Foster's Seedling well ripened, but the berries were somewhat small. The English Fruit Company, Duke Street, Grosvenor Square, W. (Mr. F. Bennett, manager), were third for heavy but unripe bunches of Trebbiano.

Baskets of Grapes.—Two classes were provided for these, the exhibits not to be less than 12 lbs. in weight. Of black Grapes there were eleven exhibitors, Mr. Timms leading with Gros Maroc, followed by Messrs. Bury and Hookings with Black Hamburg and Gros Maroc respectively. For white Grapes Mr. Peter E. Kay, Finchley, won the premier award with Cannon Hall Muscat, Messrs. McIndoe and W. Lane following in the order named.

MISCELLANEOUS FRUITS.

Peaches.—There was a good display of Peaches, Mr. W. H. Divers, gardener to J. T. Hopgood, Esq., Ketton Hall, securing the leading prizes in most of the classes, both for these and Nectarines, with handsome fruits, excellent in size and colour. With four dishes of Peaches Mr. Divers was first, showing Crimson Galande of deep colour, Princess of Wales large and handsome, Prince of Wales rich colour, and Dymond. Mr. McIndoe's second prize collection comprised Stirling Castle, Golden Eagle, Violette Hâtive, and Princess of Wales, all large and beautiful fruits. Mr. C. J. Goldsmith followed with good examples of Crimson Galande, Golden Eagle large and of a fine golden hue, Barrington and Noblesse. The competition was keen in the single dish class, no less than sixteen entering, and Mr. G. Duncan, gardener to C. J. Lucas, Esq., Warnham Court, Horsham, well deserved the first prize he secured for his handsome specimen of Barrington. Mr. Divers followed closely with Crimson Galande in fine condition, and Mr. McIndoe won third.

Nectarines.—In the class for four dishes of Nectarines, Mr. Divers led with Pine Apple, Victoria, Dryden, and Spencer, the three first-named very fine. Mr. McIndoe took the second place for Humboldt, Pitmaston Orange, Elruge, and Darwin, all well ripened, but rather small. Mr. C. J. Goldsmith followed with good fruits of Humboldt, Victoria, Pine Apple, and Albert, the last somewhat green. Mr. Divers also had the best single dish of Nectarines, Pine Apple, followed by Messrs. G. Duncan and W. Howe, gardener to H. Tate, Esq., Streatham.

A class was also provided for six dishes of Peaches and the same number of Nectarines, in which Mr. Divers was successful in winning the first prize for admirable fruits of the following—Peaches: Dymond, Crimson Galande, Princess of Wales, A Bee, Prince of Wales, and Barrington—Nectarines: Goldoni, Pine Apple, Dryden, Spencer, Victoria, and Byron.

Pears.—With three dishes of Pears (ripe). Mr. J. Butler, Sittingbourne, was first, showing *Beurré d'Amanlis*, Williams' *Bon Chrétien*, and *Doyenné Boussoch* in excellent condition. Mr. A. Waterman, gardener to H. A. Brassey, Esq., Aylesford, took the second place for Williams' *Bon Chrétien*, *Beurré d'Amanlis*, and Theodore Eyre. Mr. J. McIndoe was third. For collections of ten varieties, Messrs. Butler, McIndoe, and Goldsmith were the prizetakers in the order named.

Apples.—Mr. A. Waterman had the best three dishes of Apples (ripe), staging *Gravenstein*, *Duchess of Oldenburg*, and *Worcester Pearmain* of good size, clean, and bright. Mr. McIndoe followed, *Yorkshire Beauty* and *Ribston Pippin* being his best dishes, and Mr. J. Butler was third, *Devonshire Quarrenden* being notable amongst his Apples. In the large class for twelve dishes Mr. A. Waterman was the premier exhibitor, and he contributed some extremely fine fruits. Messrs. G. & J. Lane, St. Mary's Cray, were second, and Mr. McIndoe third.

Tomatoes.—The best six dishes of Tomatoes were those from Mr. C. J. Goldsmith, who won first honours in a class of eleven competitors all of whom showed well. The varieties were *Stamfordian*, *Reading Perfection*, *Acme*, *Hackworth Park*, *Mikado*, and *Carter's Perfection*. Messrs. G. Saunders and C. J. Waite were second and third respectively with very few points between them.

Plums.—Several classes were devoted to these, and the exhibits were satisfactory throughout. The principal prizes were secured by Messrs. Goodacre, Ward, Penfold, McIndoe, Waterman, and Chadwick. The varieties best represented were *Kirke's*, *Goliath*, *Prince Englebert*, *Jefferson*, *White and Red Magnum Bonum*, *Washington*, *Pond's Seedling*, and *Victoria*.

In the Melon classes the competition was keen, Messrs. Rodbourn, Miller, and O. Goldsmith taking the prizes amongst twenty exhibitors of scarlet flesh varieties, and Messrs. J. T. Wright, Goldsmith, and Grasettine were correspondingly successful with green flesh Melons amongst the competitors.

CUT FLOWERS.

Gladioli.—In the class for a collection of Gladioli not less than thirty-six varieties Messrs. Burrell & Co., Howe House Nurseries, Cambridge, were deservedly awarded the premier prize for a collection of ninety-six spikes, very fresh and brilliant, the most conspicuous being *Baroness Burdett Coutts*, *Enchantress*, *L'Amitié*, *Horace Vernet*, *Doris*, *Iolanthe*, *Grand Rouge*, and several bright seedlings of great promise. The Rev. H. H. Dombrain, Westwell Vicarage, Ashford, was awarded first honours in the class for eighteen spikes, consisting of *Enchantress*, *Mulatto*, *Grand Rouge*, *Crépuseule*, *Cervantes*, *Baroness Burdett Coutts*, *Meyerbeer*, *Néréide*, *Sceptre de Flore*, *Orphée*, *Dalila*, *L'Africaine*, *Arrière Gards*, *Mabel*, *Caméléon*, *L'Amitié*, *La Vesuve*, and a seedling. This collection contained more variety and colour than the second and third prize, Mr. E. B. Lindsell being placed second, and Mr. Walters third. Mr. Walters gained the first prize for twelve varieties, Mr. W. H. Apthorpe, Albion Brewery, Cambridge, the second, and Mr. W. J. Jones the third, all exhibiting well.

Asters.—Ten collections were staged for twenty-four quilled Asters, and Mr. G. S. Walters, Calne, Wilts; Mr. J. Walker, nurseryman, Thame, Oxon; Mr. W. J. Jones, Dafford Building, Larkhall, Bath, were first, second, and third respectively in the order of their names, the whole of the collections being neat and symmetrical. For twenty-four French Asters Mr. W. J. Jones was awarded first prize for a remarkably even collection, containing a large proportion of striped varieties. Mr. G. S. Walters was placed second; and Messrs. Saltmarsh & Sons third. All exhibited reflexed varieties of great substance. Sixteen collections were staged in this class.

Hollyhocks.—For a collection of twenty-four Messrs. Webb and Brand, Saffron Walden, were awarded the first prize for Walden King, M. Chater, Iris, Joy, Purple Prince, Prince Arthur, Mulberry Jam, Exultum, Cygnet, Fire King, Purity, Delicate, Henry Glasscock, Carus Chater, Constance, Golden Drop, Victor, Alfred Chater, and several seedlings. In the class for twelve Hollyhocks, cut blooms, Mr. Apthorpe; Mr. Thos. Hobbs, St. Mark's Road, Lower Easton, Bristol; and Mr. Jones were placed in the order named.

Chrysanthemums.—For a collection of early flowering *Chrysanthemum indicum* three groups were staged. The whole of them consisted of well flowered examples, Messrs. Laing & Sons, Forest Hill, gaining the premier award for a neatly trained collection, containing the following varieties:—*Fiberta*, *Alice Butcher*, Mrs. Cullingford, *Cassy*, *St. Crouts*, *Blushing Bride*, *Flora*, *Mlle. Léon Lassali*, *Delphine Caboché*, *Frederick Marronet*, *Nanum*, *Precocité*, Mrs. Burrell, *G. Wermig*, *Grace Attick*, *Blanche Colomb*, Mrs. R. Pitcher, *Lyon*, *Canari*, *Madame Jolivart*, *Madame Desgrange*, *Gentilisse*, *Comtesse Fouchre de Cariel*, and M. Picoul. Messrs. Jones & Davis, Camberwell, were placed second, and their collection contained good blooms of *Alice Butcher*, Mrs. J. Pitcher, *Nanum*, *Flora*, *Feu de Bengal*, *Madame Desgrange*, *Simon Delaux*, Mrs. Burrell, *Piercey's Seedling*, *Rose d'Été La Ami*, *Conderehet* and *Golden Fleece*. Mr. W. Piercey, 89, West Road, Forest Hill, was third for good plants, but lacking taste and effect of arrangement.

Mr. G. Osman, South Metropolitan District Schools, was well ahead for six *Coekscombs*. Mr. R. Spink, Victoria Road, Horley, and Mr. R. T.

Haynes, gardener to Mrs. Freeman, South Norwood Hill, shared the second and third honours.

Cut Stove and Greenhouse Plants.—Mr. J. Prewett, Swiss Nurseries, Hammersmith, received the first prize for a large collection, consisting of about fifty varieties, several of them being rare Orchids. Mr. A. Gibson, gardener to F. B. Atkins, Esq., Halstead Place, near Sevenoaks, was a very good second, having grand examples of *Lapagerias alba* and *rosea*, and Mr. T. N. Penfold, gardener to the Rev. Canon Bridges, Beddington, third.

Miscellaneous.—Several handsome collections of miscellaneous produce were staged both in fruit and flowers, and which greatly enhanced the interest of the Exhibition. Messrs. Veitch & Sons, Chelsea, staged 120 dishes of Apples and about 50 dishes of Pears, as well as some pot plants of Figs. Messrs. George Bunyard & Co., Maidstone, set up about 70 dishes of Apples and Pears, collections of *Roses*, *Dahlias*, *Asters*, and *Gladioli*, also a box of *Hydrangea paniculata grandiflora*. Messrs. Peck and Sons had a large collection of *Chrysanthemums*, *Dahlias* in variety, herbaceous plants, *Grapes*, *Plums*, *Pears*, and *Apples*. Messrs. G. Paul and Son an interesting collection of *Shirley Poppies* and choice herbaceous cut blooms and a box of hardy alpine *Cyclamen*; and Mr. E. Such, Rosery Garden, Maidenhead, staged a large collection of annuals and perennials.

Mr. Gordon, Lily and Orchid Nursery, Twickenham, staged a grand group of Lilies, principally *Lilium auratum rubrum vitatum*, which was much admired. Messrs. Cannell and Messrs. Laing both staged handsome groups of brilliant flowers. In Messrs. Cannell's there were as a back row about a dozen specimen plants of *Begonia Octavia* most profusely bloomed. The rest were composed of seedlings sown in February last, the whole being most attractive. Messrs. Laing's were particularly bright and effective. Messrs. Cheal & Sons staged a large collection of Apples, and Mr. John Page, gardener to A. Dixon, Esq., Leatherhead, fruit of the curious *Passiflora lauriflora* and *macrocarpa*, *Citruses*, and *Philodendron pentstemon*.

Certificates were awarded to Messrs. Laing & Co. for *Chrysanthemums*, *Comtesse Fouchre de Cariel*, a bronze Japanese of dwarf habit, and *Grace Attick*, a whorl-like Japanese form, colour white, dwarf and striking, but not of much substance.

BATH HORTICULTURAL SHOW.

SEPTEMBER 4TH AND 5TH.

ALL that is wanted to make every one of the five Shows annually held in Bath a success is fine weather. The exhibits both as regards quantity and quality are always good, but the Committee have of late years been most unfortunate in the date of their fixtures, so many excellent Shows having been marred by bad weather. Fortunately the Exhibition under notice was an exception to the rule, and as a consequence the attendance of visitors on both days was extra large. The total number of exhibitors was 279, the collective entries from these being upwards of 1500, and failures to stage were very few in number. Five large tents were filled with the exhibits, in addition to a long row of tables erected in the open air for vegetables. Altogether it was a highly satisfactory exhibition, the success being fully deserved by the Committee, of which Mr. James Chaffin is Chairman, and Mr. B. Pearson the Secretary.

Fuchsias are invariably one of the chief features at this Show, and these were fully up to the old high standard. The best nine varieties were shown by Mr. G. Tucker, gardener to Major W. P. Clarke, Trowbridge, who had grand pyramids, averaging 10 feet in height, of *C. Richman*, *T. King*, *Charming*, *Marginata*, *Miss Lucy Finnis*, *Harriett Lyc.*, *Bountiful*, *Doel's Favourite*, and *Lye's Favourite*. Mr. G. Snell, gardener to Mrs. Counsell, took the second prize for creditable plants, the veteran Mr. J. Lye, gardener to the Hon. Mrs. Hay, Market Lavington, having third place. In the class for six varieties, from which the foregoing exhibitors were excluded, the first prize was won by Mr. A. Hawkins, gardener to T. Jolly, Esq., Bath, Mr. W. C. Drummond, Bath, being second. A first prize was awarded to Mr. J. Weston, gardener to the Rev. C. C. Layard, for four *Fuchsias*, while the most successful competitors with single specimens were Messrs G. Tucker and G. Snell.

Stove and greenhouse plants were up to their usual excellence, and a step in the right direction was made in offering the principal prizes for a mixed bank of flowering and fine-foliaged plants, the latter serving to show the former off to the best advantage. Mr. J. Cypher was first, his group comprising grand specimen *Palms*, *Crotons*, *Ericas*, *Allamandas*, *Ixoras*, and other plants he so well knows how to grow and stage to the best advantage. Mr. J. Curry, gardener to Col. Pepper, Salisbury, was a fairly good second, and Mr. W. C. Drummond third, an extra prize being awarded to Mr. J. F. Mould, Pewsey. Mr. Curry had a first prize for eight fine-foliaged plants, these including *Croton Countess* and *Thrinax elegans* in good condition. Mr. H. Jones, gardener to Mr. J. Canning Doherty, was second and Mr. Drummond third. The best six flowering plants were staged by Mr. A. Taylor, gardener to C. W. Mackillop, Esq., Bath, who had *Ixora Westi*, *Dipladenia amabilis*, *Erica Eweriana*, *Bougainvillea glabra*, *Clerodendron Balfourianum*, and *Ixora Reginae* in good condition. Mr. G. Tucker was second, *Lapagerias alba* and *rosea* being noteworthy in his group, and a third prize fell to Mr. J. F. Mould. In the class for a single specimen Mr. A. Taylor was first for a grand plant of *Allamanda Hendersoni* fully 7 feet through, this being somewhat yellow in the foliage, but well flowered. Mr. Cypher was most successful with *Ericas*, but was placed

second in the class for six Orchids distinct. With these Mr. G. Pymm, gardener to Mrs. Gouldsmith, Trowbridge, was first, having a fine specimen of *Cattleya Loddigsi*, somewhat past its best, *Cattleya Leopoldi* with three spikes, *Vanda suavis*, *Oncidium flexuosum*, *Lælia Leeana* and *Zygopetalum Mackayi*. Mr. Cypher staged *Cattleya Gaskelliana* with four spikes, *Dendrobium formosum* with three spikes, and other well flowered plants. The first prize for a new or rare plant was awarded to Mr. G. Tucker for a small trained specimen of *Schubertia grandiflora*, carrying twelve of its *Stephanotis*-like trusses of bloom. Mr. Cypher was second with *Cattleya Wallisi*, this having pure white flowers with the exception of an orange yellow throat to the lip.

For twelve varieties of exotic Ferns Mr. G. Tucker was first; Mr. T. Tucker, gardener to T. Carr, Esq., Tiverton, being a creditable second, and Mr. H. Jones third. The best six varieties were shown by Mr. W. Marchant, gardener to Jerome Murchant, Esq., Bath, the second prize going to Mr. J. Hiscox, gardener to E. B. Rodway, Esq., and the third to Mr. Brown, gardener to C. Bailey, Esq., Frome. The first prize group of six varieties of Zonal Pelargoniums staged by Mr. G. Tucker were exceptionally good, and other successful exhibits in the various classes for Pelargoniums were Messrs. H. Jones, A. F. Cray, S. Tottle, and E. B. Tittle. Tuberous Begonias, both double and single, were well represented, the prize lot in each instance, and which were shown by Mr. C. Richman, gardener to Mr. G. H. Palmer, being worthy of special notice. Messrs. G. Cooling & Sons, Bath, were first for well flowered *Lilium auratum*, and were second to Mr. T. Carr for four varieties of *Liliums*.

This year, for the first time at the autumn Show, prizes were offered for groups of miscellaneous plants arranged for effect, space not to exceed 100 square feet, and this attracted three competitors. Mr. J. Cypher was easily first with a very light and tasteful arrangement. The front was irregular in outline, being much the fullest in the centre, and was very prettily finished off. From a groundwork of Maidenhair Fern sprung numerous well grown Crotons, Palms, Dracænas, notably *D. Lindenii*, Orchids, *Liliums*, and other elegant plants. The common error of crowding too many plants together was avoided, yet no unsightly pots were observable. A somewhat similar arrangement gained Mr. Curry the second prize, the third going to Mr. R. B. Cater for a more formal but fine group.

One tent and part of another were devoted to cut flowers, the competition in every class being close. Roses were well shown. With thirty-six varieties Messrs. J. Jefferies & Son, Cirencester, took the lead, the best being Mrs. Jowitt, Alfred Colomb, Duke of Teck, Etienne Levet, Comtesse de Choiseul, Duc de Roban, and Charles Lamb. Mr. J. Mattock, Oxford, was second, and Messrs. Keynes, Williams & Co., Salisbury, third. In the class for twenty-four varieties Mr. J. Mattock was first, his best being Ulrich Brunner, Souvenir d'Elise Vardon, C. Mermet, Duke of Teck, Dupuy Jamain, Auguste Rigotard, Souvenir d'un Ami, and Her Majesty. The second prize was awarded to Mr. A. H. Gray, Bath. His stands comprised Teas only, the best of these being Comtesse Nadailac, Jean Ducher, Marie Van Houtte, Niphetos, Maréchal Niel, Souvenir d'Elise Vardon, and The Bride. Dr. Budd was third. Gladioli made a fine display, the thirty-six varieties shown by Mr. G. S. Walters, Calne, and awarded the first prize, being especially good. In this class Mr. R. H. Poynter, Taunton, was second, while with twelve varieties Mr. S. Tottle, Taunton, was first, Messrs. J. Jefferies and Son second, and Mr. A. A. Walters third. Messrs. Heath & Son, Cheltenham, were first for twenty-four varieties of Dahlias, Mr. G. Humphries, Chippenham, being a close second, and Mr. J. Nation third. For Fancy Dahlias Mr. G. Humphries was first, Messrs. Heath and Son second, and Mr. T. Hobbs, Bristol, third. Asters generally were very good, and with these the principal prizewinners were Messrs. W. J. Jones, G. S. Walters, and Walters Brothers. The first prize for twenty-four varieties of choice cut flowers was won by Mr. R. Richards, the second going to Mr. R. Wait. Messrs. G. Cooling & Sons were first for cut herbaceous flowers, Mr. A. A. Walters being second, while the first prize for annuals went to Mr. A. Hawkins, and the second to Mr. G. Garraway. Mr. C. Winston, Clifton, was well first for a beautiful hand bouquet, and was also first in the class for an epergne.

Fruit filled one good sized tent, and, as usual, came in for a great share of attention. There were six competitors with eight bunches of Grapes in four varieties, but the Judges had no difficulty in awarding the first prize to Mr. W. Taylor, gardener to J. Chaffin, Esq., who had grandly finished Muscat of Alexandria, perfect bunches of Alicante, good Alnwick Seedling, and Madresfield Court. Mr. J. Bury, gardener to C. Bayer, Esq., London, a new exhibitor, was a creditable second, his weak point being Foster's Seedling. He had very fine Black Hamburg, excellent Alnwick Seedling and Madresfield Court, and well coloured but slightly rubbed Alicante. Mr. J. Gibson, gardener to Earl Cowley, Draycot Manor, was a good third, his best being Black Hamburg and Madresfield Court. Mr. J. Bury took the lead in the class for Black Hamburg, having compact bunches with extra large well coloured berries. Mr. Gibson was a good second, and Mr. J. Ellicott, gardener to H. W. Tugwell, Esq., a close third. For any other black variety Mr. W. Taylor was first with Alicante in superior condition. Mr. W. Fisher, gardener to E. G. Peacock, Esq., Bath, being second with good bunches of the same variety. In the Muscat of Alexandria class Mr. W. Taylor was again first, having two handsome bunches; Mr. J. Gibson was second.

The competition with any other white variety was less keen than usual. Mr. W. Askell, gardener to J. B. Brain, Esq., was first for beautifully ripened Foster's Seedling; the second prize going to Mr. W. Carpenter for the same variety in good condition. A class was provided

for local Grape growers, and in this the competition was keen and good. Mr. J. Brimble, gardener to J. Fortt, Esq., was first for fairly good Muscat of Alexandria; the second going to Mr. Carpenter for Alicante. Melons were largely shown, but many of them would not stand the tasting test. In the class for a green-flesh variety Mr. M. Cole was first for a good fruit of Imperial; the second going to Mr. W. Matthews for Eastnor Castle. For a scarlet flesh Melon Mr. W. Allen, gardener to G. P. Hallett, Esq., was first with a well-grown fruit of Scarlet Invincible; Mr. G. Hiscox being second with Blenheim Orange. Peaches and Nectarines are still cut at Bath, but there ought to be no need for this disfiguring process. A good dish of Peach Bellegarde gained Mr. A. Miller, gardener to W. H. Long, Esq., Trowbridge, the first prize; Mr. T. Head being second with Royal George in good colour. Mr. R. H. Taylor had a first prize for Nectarine Pine Apple; and Mr. G. Pymm was second with a much finer dish of the same excellent variety. Plums in great variety, Apples, Pears, Cherries, and Figs were all extensively shown, the quality throughout being superior. Mr. A. Miller was the only exhibitor of a collection of fruit, and fully deserved the award of a first prize. He had fairly good Alicante and Muscat of Alexandria Grapes, Rood Ashton Melon, Bellegarde Peaches, Pine Apple Nectarines, Brunswick Figs, Bon Chrétien Pears, and Jefferson Plums, all in excellent condition.

Vegetables were so numerous and well shown as to merit a fuller notice than can be given them. The best out of several collections of twelve varieties was staged by Mr. G. H. Copp, gardener to W. E. Erle Drax, Esq., Sherborne, who had very fine Cauliflower, Autumn Giant; Carrot, Sutton's Intermediate; Tomato, Perfection; Potato, Sutton's Seedling; Beet, Pragnell's Exhibition; Cucumber, Tender and True; Pea, Telephone; Parsnip, Ellacombe's Improved; Leek, The Lyon; and Celery, Sutton's Giant White. Mr. T. Wilkins, gardener to Lady Theodore Guest, Blandford, was a good second; and Mr. G. Garraway, Bath, third. Mr. Copp was also first for six varieties (the prizes in this class were provided by Messrs. Sutton & Sons, Reading), Mr. Wilkins being second, Mr. A. Spry third, Mr. T. Tilley, Banwell, fourth, and Mr. J. Hall fifth. Messrs. Webb & Sons, Stourbridge, also offered prizes for six varieties of vegetables, and for these the competition was very good. Mr. C. J. Waite, gardener to the Hon. Colonel Talbot, Esher, was first; Mr. G. Garraway second, and Mr. Copp third. Baskets of salad were very large. Messrs. Tylee and Evry being the prizewinners. The best dish of Tomatoes was shown by Mr. Cray, Frome, who had Perfection at its best. Dr. Budd was second. The cottagers also made an excellent display of vegetables.

Non-competitive exhibits were numerous. Noteworthy among these was a fine collection of cut Roses, Gaillardias, Dahlias, and other flowers shown by Messrs. G. Cooling & Son, to whom a certificate of merit was awarded. Messrs. Cooling & Son also had a good collection of named Apples and Pears, gathered from their nursery trees, and which it is to be hoped proved instructive to the numerous gardeners who critically inspected them. A certificate of merit was awarded to Mr. J. Mattock for a fine display of Tea Roses in bunches; and also to Mr. A. H. Gray for several stands of well-grown Teas.

FRUIT FORCING.

VINES.—Houses of Ripe Grapes.—Black Hamburg and other thin-skinned varieties are liable to have the colour taken out of them by hanging under powerful sun. Some netting should be drawn over the lights to prevent it. Black Hamburgs and Foster's Seedling will bear a moderate amount of air moisture, provided it be not stagnant, and it is very necessary for the benefit of the foliage; but Madresfield Court does not endure moisture to the same extent as Black Hamburgs, and must be treated accordingly. It, however, loses colour quite as badly, and must be shielded from the direct rays of the sun. Muscats hanging on Vines with the roots in outside borders will keep a long time, protecting the roots from heavy rains. A covering of dry fern, shutters or tarpaulin, answer, but glazed lights are better, placed in a sloping position for throwing off the wet, as they admit sun heat, and retain it for warming the border. If the foliage is not sufficient for the protection of the tender skins of the berries some light shading will be necessary, particularly where the houses are glazed with large panes of glass. Hexagon netting answers well, and drawn over the ventilators excludes wasps, which have appeared in force when we were congratulating ourselves on their comparative scarcity. The thick-skinned varieties will require, whether the Grapes are to be kept on the Vines or in the Grape-room, liberal ventilation with gentle fire heat for the maintenance of a certain circulation. With the Grapes ripe gradually reduce the strong laterals as the days decline in length, and keep the foliage healthy by means of a moderate supply of moisture on the paths and floors sufficiently early in the day to admit of the atmosphere becoming light and buoyant before nightfall.

Lifting Vines.—Where lifting and relaying the roots of early and

midseason Vines is contemplated, it should be seen to as they are cleared of the crops. The sooner it is done the better. Good loam, with some brick and lime rubbish, and a liberal admixture of charcoal and crushed bones, will meet all requirements in respect of compost. See to the drainage, make it satisfactory, and follow on with turf grass side downwards, or preferably a 3-inch layer of lime rubbish. Keep the roots near to the surface, always bearing in mind that a narrow border well filled with roots is preferable to a large mass of soil at the onset, as the roots can be more easily excited and fed at the proper time. The Grapes, too, in a border well in hand invariably set and colour better. Always choose dry weather for making the border. Cover it when finished with good stable litter, and keep the interior of the house close and moist until the foliage shows signs of fresh root action having set in, then ventilate freely and keep the air dry. In all cases, especially cold wet localities, the Vines should have inside as well as outside borders, as the roots can then be lifted and relaid in either of the borders without injury to the following year's crop.

PINES.—Young Pine plants always present a luxuriant appearance at this season under liberal and proper treatment. Sun heat being now on the wane, greater care will be necessary in the management to prevent the foliage becoming soft, and measures should be taken to consolidate it by a drier atmosphere and artificial heat. Syringing will only be needed occasionally, and it should be done early in the afternoon of bright days. Water must only be given when absolutely necessary, then afford a plentiful supply of weak liquid manure in a tepid state. The bottom heat should be kept steady at 85°, or between 80° and 90°, and pay particular attention to the ventilation, which is important at this time of year. Plants in a luxuriant condition should have air at 80°, above which ventilate liberally, especially on warm sunny days, and close the house for the day at 80°. The night temperature should be maintained at 65°, allowing 70° to 75° by day artificially.

Fruiting Plants.—These should be brought together in a structure suitable for finishing the fruit well. Plants that are intended for starting into fruit early in the year should be selected from those that were started last spring, and be arranged not later than the end of this month where they can rest for six weeks. Those on which the fruit is swelling should be encouraged with liberal heat and moisture, keeping the night temperature from 70° to 75°, and that in the daytime from 80° to 90°, closing the house at 85° with sun heat.

STRAWBERRIES IN POTS.—The plants are making very satisfactory progress. In the earliest plants the crowns are becoming plump, sufficiently so at least for the detection of plants that will not be available for early forcing, and which should be removed at once, even those about which there is a suspicion of being barren, making good the deficiency from the surplus stock. Worms and weeds are troublesome, also runners. Lime water will expel worms, and the weeds and runners can be promptly removed. The pots should be wide enough apart to allow of the sun and air having free access to the foliage. The crowns, which in some are numerous, particularly Vicomtesse Hericart de Thury and Sir Charles Napier, should be reduced to the central or stronger one, not deferring it until they have attained to a considerable size, but as soon as they can be taken hold of with the finger and thumb and lifted out of the socket. This will concentrate all the vigour in the main crown; those will afford strong flower spikes, and then by selecting the largest and best formed flowers a crop of fruit will be insured, large and creditable to the grower. Any late runners may yet be potted, and with good attention they will be serviceable for late work in 5-inch pots, and may afford fine fruit and collectively as full a crop as those in larger pots.

THE BEE-KEEPER

NOTES ON BEES.

TIERED HIVES.

THE word tier is a term improperly used instead of storifying. I have indeed used the expression, but it is incorrect. I have taken up this subject in reply to what "Felix" says at page 167, accidentally discovered by me on searching for some notes amongst accumulated correspondence in the Journal for August 20th, which had never been opened, hence my delay in answering. The text of "Felix's" remarks is the following, which I suppose is taken from an article written by me:—"While tiered hives are undoubtedly the largest producers, still it is a loss to attempt frustrating the swarming mania, and as swarms always work the best we should take them the first opportunity, and make the most of them." I have taken great pains to lay before your readers every phase of bee-keeping, including that which "Felix" says is "one to which many will, in my opinion, take great exception, and therefore in order to prevent what appears to me to be a wrong

impression from being circulated it is necessary to consider the meaning of these words." The causes of swarming are not well understood by the majority of bee-keepers. "Felix" appears to agree with all I have said—in fact, endorses what I say, and yet adds it will cause a "wrong impression," but gives no information whatever to prevent it further than to "manage skilfully." I throw down the gauntlet to "Felix," and now let him tell us all how to manage our bees "skilfully," so that they will not swarm. I say it cannot be done otherwise than by carefully giving more breeding space at the time a young and fertile queen is introduced after the old queen is deposed, and this course is exactly what "Felix" deprecated. My notes made at the Heather bear greatly upon the subject, and have appeared in these pages, for the sole purpose of enlightening bee-keepers generally, and I am glad to say they are being acted upon by many who read my notes; but I shall wait patiently for "Felix's" forthcoming remarks on managing bees "skilfully," how to prevent swarming.

Swarming takes place when more than one queen exists in one hive at the same time, and occurs from March till October. We have had a swarm issue on different occasions, the day after two had been joined in the month of October. Whenever a queen becomes incapacitated from any cause and unable to deposit eggs in the cells prepared for that purpose, queen or royal cells are brought forward, and swarming takes place if the weather is favourable, which nothing but the excising of all but one royal cell will prevent. Extra room will not do it, no matter how or where it is given, and I do not believe that one variety of bee swarms more readily than another. One variety gives more after swarms than another does, but all are actuated by a natural propensity.

AT THE HEATHER.

A very large swarm issued from a Carniolian prime swarm owing to a young queen and part of a swarm being blown on to it. The bees and queen were allowed to remain unmolested for two days, then, owing to the presence of two queens, the swarm issued leaving the queen regnant as she was previously. I know whereof I write, and do so advisably, and am open to conviction when wrong, but unless "Felix" offers stronger proof that I am wrong and misleading I must continue to advise as I have hitherto done.

DRONES.

Drones are sometimes a great drawback to bees when at the Heather. If a few wet days intervene, and no honey is coming in, when a bright day occurs the bees take to killing, or rather hunting out the drones, which are strong, and return again, or enter weaker hives, much to the annoyance of the bees, deterring them from gathering honey even although it be plentiful. The Punic stock was greatly taken the advantage of in this respect, numerous drones took refuge in it, and were perhaps the cause of these bees gathering less honey than the others. It is generally believed that when bees kill their drones it is a sure sign the queen is fertilised. This is far from being the case at the moors; several only a day or two before swarming, and even after it, turned out their drones and drone grubs in a wholesale fashion.

COMPETITION.

As in former years bees are here from different parts of Scotland and from over the border. All owners have their favourite hives. I have no alternative, when I take all there is to contend with, but to adopt the Lanarkshire storifying hive, so well adapted for bee-keeping in all its phases. Its comparatively large internal capacity, combined with its small outside dimensions and construction for safety to bees and co-passengers, warrants its recommendation. Two hives from Carlisle stand a little distance from my own; they measure about 217 cubic measure, certainly out of all proportion to their internal capacity. From appearance these hives cannot weigh less than 1 cwt. each when empty, while the size is sufficient to prevent most people adopting them, practically putting an end to taking bees to the Heather. The bees of one of these

hives worked well, and the hive appears to be heavy, as I had to put my shoulder to it before one side of it could be raised from the ground. My own hives tare run about 30 lbs., so when compared with these bulky ones of the south, and taking the conveyance into consideration, all will perceive my reasons for adopting the lighter form of hive.

After the bees are once placed on their stands there is not so much difference in the ingathering of honey by those in differently formed hives. The advantages are gained by using light ones when convenience and expenses are concerned, and for wintering and spring management, which latter means much and often all in the way of profit. Of course, our form of hive is more suitable for getting filled and finished supers free from colour than are other makes, but the aggregate gathering by any colony at the Heather depends more upon the variety and number of bees in a colony, and its proximity to the Heather, than upon the form of hive. The nearer to the Heather that bees are situated the more honey will they gather and with less loss of bees. This has been fully demonstrated in our friendly competition this year, and we advise all to place their bees as near to the Heather and in as sheltered a situation as possible.

PUNIC BEES.

I wish to thank "A Hallamshire Bee-keeper" for his reply to my query, but he appears to have misunderstood it. It is not the earliness of the day, but at the early age of six days that the young Punic bees began to work. I am glad to observe that he is making investigations as to bees swarming, and hope he will give us the benefit of his discoveries. Like him, I have had a swarm issue from a hive, leaving neither queen nor the means of raising one behind.

FEEDERS.

I observe what "Felix" says about feeders. One, nearly if not a hundred years old, lies before me of the same construction he advises; and, moreover, I never saw a float feeder made otherwise than the way he describes as an improvement.—A LANARKSHIRE BEE-KEEPER.

TRADE CATALOGUE RECEIVED.

T. S. Ware, Tottenham.—*Catalogue of Peonies and A B C Bulb Guide, 1839.*

All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Lichen in Lawn (J. P.).—Your lawn is either wet or poor, or both. Rake out all the moss and lichen you can, drain the ground if necessary, and top-dress with good loam, wood ashes, and lime.

Welshman Plum (R. G.).—We prefer to withhold the publication of our opinion respecting this Plum till we are supplied with

information relative to the origin of the variety. Why not send specimens to the Fruit Committee of the Royal Horticultural Society?

Virginian Creeper (W. B. K.).—Soil and climatal influences affect the colour of the leaves of this, in common with other deciduous plants and trees. Autumn foliage tints last year were not nearly so bright as they were the year previous, and this year they are comparatively dull in many districts, probably in consequence of the cold wet weather that prevailed a few weeks ago. If the roots of your Ampelopsis have not entered a cold clayey subsoil, the leaves will assume their bright red tint when the summers are favourable to its development. We have seen several examples of the leaves changing to purple instead of red.

Muscat Grapes Decaying (G. E. W.).—Undoubtedly, as you say, it is most dispiriting for a gardener to make such a good start, and set such a good crop of Muscats, and then be denied fuel for ripening the fruit. During the cold, wet weather that followed the withholding of fuel the Vines received a severe check, and that was unquestionably the cause of the present unfortunate condition of the Grapes. They have not ripened, and if no artificial heat is provided the probability is that the wood will fail to ripen too, and the Vines may be permanently injured. The fault, however, is not yours. The treatment you describe as having given up to the time the fuel was disallowed was quite correct, and if it had been pursued we doubt not that the enhanced value of the crop would have been considerably greater than the amount that has been saved in fuel. If a gentleman desires to have even fairly good Grapes without artificial heat he must grow other than Muscats.

Compost for Vine Border (A. S.).—We do not advise your adding anything in the form of manure to the ingredients named, but should prefer three or four cartloads of strong loam to the "medium." If the texture of this is what we understand it to be, we are inclined to fear that the border will be too light, and we should not have used more than half the quantity of lime rubbish you state to loam of medium texture. The border will be quite rich enough for some time, and especially as you will no doubt mulch the surface with manure after planting. We should take care the compost is neither too wet nor too dry, then press it down rather firmly, and not make the border the full width at once. Four feet will be ample the first year, and perhaps longer if care be taken that the soil does not get dry, particularly near the outer edge. The best Vines we have seen this year have made two seasons' growth in a rooting space not more than 3 feet wide, but another section will shortly be added to the border. Manurial ingredients can be applied in the form of top-dressings if the condition of the Vines suggest that they require additional support. Your second letter shows conclusively the inadequacy of your first question. The mixture suggested will grow healthy, fruitful Vines under otherwise good management, and without this either that or any other compost will fail to produce the best of Grapes.

Renewing Outside Vine Border (J. G.).—As the inside border was renewed three years ago, and now, as you indicate, contains active roots, you may carry out your proposition; but is it not a little strange that if the roots are plentiful near the surface and the soil good that no improvement in the Vines followed? However, admitting the roots, we should take care the border containing them is thoroughly moist, and should then not hesitate to cut boldly through the roots 8 feet from the house in the outside border, removing the whole of the soil, cutting off all bruised ends smoothly with a knife, notching also some of the larger roots, retaining all of a fibrous nature, keeping the whole of them moist, and place them in fresh good soil containing a large admixture of wood ashes. This we should do as soon as the fruit is cut and before the leaves fall, syringing and shading these if necessary for keeping them fresh for inciting fresh root-action at once. We have known the most satisfactory results follow this method of renovation when conducted by able gardeners, and Vines greatly improved the first season. We suspect you have been overcropping the Vines and possibly overcrowding the foliage, or the Grapes would scarcely shank so "terribly" with "roots near the surface in the inside border." As the site is low and the subsoil clay by all means raise the border and keep the roots in the good soil provided.

Bottom Heat Chamber—Winter Cucumbers (A. A. B.).—A rough and ready, cheap, and long lasting covering for hot-water pipes is found by many persons in clinkers and stones of various sizes, and the larger the better for the bottom, smaller yet open at the top. A few old slates, tiles, or boards as are most readily obtainable are placed on these, then long manure and leaves before placing in the soil. Iron or strong wood supports, with a flooring of slates, are employed when the materials are at hand or can be had cheaply. Individual means and local resources generally determine the matter in such cases as yours. For producing good crops of Cucumbers, and liberating the house in March, plants ought to have been raised more than a month ago. We do not say you will fail by sowing now, as we are unacquainted with your cultural experience, but we have a strong opinion that the longer you delay the less will be your chance of a profitable yield by the time named. We have seen good crops of Tomatoes grown in beds after Cucumbers without removing the soil, but obviously we can give no assurance that you will equally succeed, as much depends on the soil used and general management. If you have not grown Cucumbers in winter you must not expect great profits from the first endeavour, though there is the probability of your making a fair return if the house is suitable and you accord the plants the requisite attention.

Helianthus multiflorus var. Soleil d'Or (W. B. H.).—Please do not send us any more blooms of this variety, for it is no pleasure to open box after box and not find one flower in a fit state for engraving. Had you simply done as we suggested, packed the blooms in some newly cut grass, and we think there is some in Ireland, they would have arrived as fresh and bright as when cut from the plants, but by coiling each in dry paper the moisture was extracted from the petals, and the blooms reached us much nearer black than yellow, besides being crushed out of shape. It is most disappointing to see beautiful flowers spoiled by bad packing, and if all you send out reach those for whom they are intended in the same condition that every one has been received here we have no hesitation in saying that the merits of the variety are by no means fairly represented. The letter you send is not suitable for publication, and we do not require further evidence to satisfy us of the distinctness of your variety from the one usually grown in gardens. Plants of both are now flowering at Chiswick, and the difference is obvious. Indeed there is practically as much difference between the two as between a bad Anemone flowered and a good reflexed Chrysanthemum, and we agree with Mr. Barron in regarding the double perennial Sunflower named Soleil d'Or as an acquisition to tall growing border plants for flowering during late summer and early autumn.

Vines Failing (J. C., Somerset).—We wish all seekers for information would state the circumstances of the cases they bring before us as clearly as you have done. When the leaves, become "very badly" attacked with red spider, the best of soil cannot avail in preventing injury to the Vines and disappointment in the crops of fruit. We do not consider the condition of the Vines by any means entirely due to the insects in question. The leaves have simply languished and changed prematurely through lack of support. You say that on examining the border a few days ago you found it "very dry," that is quite sufficient to account for the state of the Vines, and would render them particularly liable to the attacks of the small but destructive enemy. No matter how good the soil may be its virtues are inert in the absence of moisture. We usually find the best of Grapes when the Vines are in firm soil, yet a little springy to the feet, not hard like a cement floor, nor soft so that each step makes a deep impression. But we should decidedly object to painters tramping on a Vine border, and possibly when the surface was not always dry, and should provide them with boards for use in working, and if they did not use them they would have to work elsewhere. We do not think you can justly blame the men for making the border hard if you did not find them boards to step on; nor are the insects to be blamed for turning the leaves yellow. The great mistake and source of the evil was in allowing the border to become so dry. The remedy is to lose no time in making it thoroughly moist. Point it over carefully, not of necessity deeply, but break the close crust, and pour on water copiously as the work proceeds. As the border is concreted and drains and outfalls provided, do not consider the watering adequate till some escapes into the drain. For effecting this you will probably have to go over the border twice. The first time we should use clear water, the second liquid manure, with a sufficient interval between the applications for the surface to get just dry enough for boards to be used by the workmen without dragging up the soil when they are turned over. We suspect the soil is poor as well as dry. Some pastures contain little or no Vine food. The drainings from manure heaps would do the Vines good; failing this rich liquid, procure some good guano and dissolve it at the rate of an ounce to each gallon of water. Cover the border well with manure instead of reeds, and let the rains wash its virtues into the soil. When Vines are forced, and especially if the soil is strong and very retentive, throwing off the rains of winter is very beneficial; but with your well drained and concreted border, probably porous soil, and light rainfall, also no artificial heat in the house, the practice may easily be more injurious than beneficial. Moisture and enrich the border, keeping it moist during the summer from the base to the surface with the aid of mulchings, and the Vines will improve. Red spider will then be more easily prevented taking possession if a genial atmosphere is maintained, ventilation properly conducted, and the syringe judiciously used.

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (T. S.).—1, Josephine de Malines. 2, Beurré Diel, good. 3, imperfect, perhaps Beurré Bachelier. 4, not recognisable. 5, Cockle Pippin. (W. W.).—1, French Crab. 2, Keswick Codlin. 3, Jolly Beggar. 4, Hambledon Deux Ans. 5, Court of Wick. 6, Nonesuch. Those are the names as nearly as they can be determined from solitary specimens, all of which are not good representative examples. (J. P.).—1 and 6 cannot be identified. They are probably local and of no value. 2, Warner's King. 3, Adam's Pearmain. 4, Dumelow's Seedling. 5, Boston Russet. (R. C. A.).—1, Not a variety of Orleans, probably a wildling. 2, not known and not worth growing. 3, Denyer's Victoria. There is only one Victoria. It is a Sussex Plum, and was known as Cox's Emperor, but obtained and sent out at a high price as a new variety by a Brixton nurseryman named Denyer. The Plum you refer to as an inferior Victoria is either another variety, or its inferiority is due to age of tree, soil, or position. 4, Denbigh or Cox's Emperor, very good in size and quality. 5, Kirke's, a fine fruit of one of the best of purple dessert

Plums. 6, Probably the Nectarine Plum. We cannot answer your last question at present; it is the first of the kind we have received. (A. J. C.).—Warner's King.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (Somerset).—Crataegus glabra is synonymous with Photinia serrulata, the latter being the accepted name. (G. F.).—Passiflora Buonanaparte and Oneidium flexuosum. (A. S.).—We have repeatedly requested that flowers sent for name be not packed in cotton wool. Your flowers were dried almost beyond recognition, but they appear to be Oneidium ornithorhynchum. (J. C.).—1, Saccobolium Blumei; 3, Cattleya gigas; 4, Cattleya crispa. The others were not recognisable, and some small brownish flowers (possibly an Oncidium) were shrivelled up in the cotton wool employed for packing. Please note our request above. (W. F.).—1, Helenium pumilum. 2, Atriplex hortensis. (W., Reading).—A is Cattleya Forbesi. B is a species of Bulbophyllum, which cannot be determined at present, though it has been carefully compared with the specimen of this large and difficult genus preserved in the Kew Herbarium. Possibly it may be yet identified, and if so we will send you the name.

COVENT GARDEN MARKET.—SEPTEMBER 11TH.

No alteration. Market very quiet.

LANDLORDS' FARMING.

MICHAELMAS will soon be here again, bringing in its train much that will cause anxiety to landowners having more farms falling upon their hands, for the cultivation of which capital must be forthcoming out of means already much straitened by what is practically a compulsory reduction of rent; for, whether such reduction has been voluntary or in compliance with the tenants' demands, its cause was beyond the control of either landlord or tenant. To the landlord whose knowledge of farming is of a mere superficial nature the falling in hand of farms must appear a serious disaster, and it is probably owing to some such feeling that the rent upon some estates has been brought down so low as hardly to cover the landlord's liabilities. Anything rather than farms in hand is the feeling to which such an absurd reduction gives expression, but it is undoubtedly as erroneous as it is to suffer land to go out of cultivation. No sympathy have we with any such shirking of responsibility; the situation must be faced boldly, and its difficulties overcome.

Given sufficient capital for the purpose, the chief difficulty consists in reclaiming land out of condition. Well indeed would it be if the clause binding tenant to farm the land in a husband-like manner were more strictly enforced, and tenants made to reform who are found to be "taking it out of the land" by exhaustion of fertility and low cultivation generally. It is unnecessary to dwell upon the folly of a tenant acting in this way, for it is obvious that his interests suffer equally with those of the landlord. If only the land is so porous as to admit of the passage of water through it, if the drainage is sound, the soil clean and tolerably fertile, then, indeed, profitable farming is at once possible; but if the soil is deficient in any of these indispensable conditions to successful cultivation it must be set right at the outset. It is doing this that so frequently renders landlords' farming unprofitable for the first two or three years. Very positive statements are often made that farmed-out land requires at least five years' careful treatment to restore it to a really sound condition. With this dictum we do not agree, for we have proved beyond a doubt that in pure home-mixed chemical manures we have an infallible agent for the speedy restoration of fertility in an economical manner, and which fertility is subsequently sustained by the judicious use of such manures, by the ploughing in of green crops, and by sheep folding.

The selection of the implements and live stock is a preliminary matter to which much thought must be given. To farm profitably under ordinary conditions only from one-third to one-half of the land must be kept constantly under the plough, which means that we can manage perfectly well with half the usual number of horses, less implements, and less men. By a simple calculation we can easily ascertain the quantity of corn required for home consumption for the year by horses, cattle, sheep, and pigs. After the allotment of sufficient land for that purpose we may consider if it is worth while going into the cultivation of corn for sale at present prices. What quantity of corn will the land yield per acre? What will be the cost? What the profit? Compare this with the cost and profit of sheep, pigs, cattle, and dairy farming, allow a safe margin for losses, and there should then be a sound basis for action. What we deplore so much is the blind following of custom, the reckless heedless extravagance which has no guide to action, no plan or purpose, and thus absolutely courts failure.

Be it understood that if less corn is grown, it by no means follows that most of the land is to be laid down to permanent pasture even by landlords. A fair proportion of such pasture there

always must be, with enough long layers and other forage crops to supply home requirements, and for sale if there is a convenient market. Whatever system is followed there must be thorough cultivation of the pasture. It is usually considered that ordinary pasture will not carry more than two or three ewes per acre, but surely it will be granted that pasture may be so much improved, either by sheep folding or an annual dressing of chemical manure, as to carry twice or three times that number. We know that it may—aye, and at a proportionate increase of profit too; but then we avoid the use of farmyard manure, and prefer less costly and more efficient fertilisers for surface dressings. This is a point of especial importance, always to be kept fully in view—*i.e.*, not to enrich or improve the soil at such an extravagant outlay or process of cultivation as to render profit impossible. Judicious economy must be the guiding principle. We must know when and how to spend to advantage, and when and how to save. Where is the good of producing heavy crops if the cost of doing so is so high as to preclude all possibility of profit? It is precisely this blunder which has led to a feeling of prejudice against high farming, but the term is an elastic one, capable of several interpretations.

(To be continued.)

WORK ON THE HOME FARM.

Harvest work is in an advanced state, a few more fine days only being required to enable us to finish the Barley. Spring Beans are the latest crop with us, and though the growth is not nearly so vigorous as that of last year the stalks are well set with full pods. Peas were ready for carting quite as early as winter Oats, and the crop is satisfactory. A stack of Peas near the pig yard is most useful if left unthrashed, and so used not a Pea will be wasted, and the pigs will consume much of the haulm as well. Store pigs are now out upon the stubbles daily, and are driven to water at midday. Plenty of thriving store pigs upon the stubbles is a sign of good management, and when they again come into the yards they may either be finished quickly for the London market, or all or part of them kept for bacon hogs. It is usually found to answer best to sell quickly, as there are other younger pigs to follow, and the sows will consume most of the tail corn later on. As we anticipated, the new Wheat is of good weight, but so far the yield per acre is not satisfactory. We have, however, thrashed so little that a fair estimate can hardly be made. The condition is excellent, and the highest price for the last week in local markets was 3s. per quarter; some Barley realised 36s.

The sowing of green crops for spring is being done as fast as the land can be got ready. *Trifolium incarnatum* sown last month is now up and growing so freely after the recent downpour that the plant will be well established before winter, and will afford some valuable fodder in spring. Rye sown now is of especial value for following the late sown Turnips, and it should not be forgotten that its earliness will depend very much upon the condition of the land, that in fertile soil always being ready for use two or three weeks before other Rye in poor soil. The fact should be clearly understood that early vigorous growth does not depend altogether upon the weather. Much may be done for this crop by a dressing of 1 cwt. per acre of nitrate of soda next February, so that if it is difficult to apply manure now under the pressure of autumn work the nitrate of soda may be depended upon to promote a brisk vigorous growth. Winter Tares and winter Oats will also be sown now before Wheat sowing begins, the Oats often being useful for sheep grazing when spring feed runs short, both the Rye and winter Oats affording a useful crop of grain after the grazing.

METEOROLOGICAL OBSERVATIONS.

1st.—Fair, but almost sunless. REMARKS.
2nd.—Fine, but frequently cloudy; heavy showers, with frequent distant thunder and lightning from 7 P.M. till far into the night.
3rd.—Dull and damp early; very gloomy and dark from 9 A.M. till 11, and gradually clearing; the afternoon fine and generally bright. 5th.—Overcast all day.
4th.—Cloudy early; fine bright day. 6th.—C cloudy early; bright day.
7th.—Dull till 10 A.M., then bright till 1 P.M.; frequent showers in afternoon and evening. Temperature about 3° above the average, the minimum being 8° higher than in the preceding week, while the mean maximum is exactly the average. The thunderstorm on the night of the 2nd, which was very slight in London, was exceptionally violent and destructive in West Essex, and the rainfall at some stations enormous; at two it exceeded 4 inches.—J. J. SYMONS.

SOME time ago a correspondent, I forget who he was or when he wrote (but that is immaterial), said he failed to see how liquid manure given to fruit trees in the winter could be of any benefit, as the roots were then in a dormant state. In the first place they are not in a dormant state after the leaves fall, though they do not imbibe nutriment from the soil to anything like the same extent as in summer; and in the second place they do not imbibe what they need either in summer or at any other time when the food for which they are hungering and thirsting is not in the soil. That is the condition of thousands of trees in summer and winter. They have been planted for years or generations, and manure may or may not have been placed round their stems from time to time. Be that as it may, the roots have deprived the soil of all that was good for the trees, and gone further and deeper in search of more—seeking, but finding not that which is necessary for their sustenance. They have lived but not prospered, and never can prosper until the impoverished food store (the earth) is replenished—supplied with matter which is essential to their health.

Unquestionably this may be given with great advantage in summer if obstacles do not forbid its application then, and in no other way can it be so quickly effective as in a liquid state. At no period are the roots of fruit trees of all kinds, including Vines, so active as now, and at no period can so much nutriment be imbibed from the soil in a given time when the earth is in a fit state for its reception. It is not in a fit state when it is dry, and I have no hesitation in saying that the best of liquid manure that can be procured does immeasurably less good applied in summer, when the soil, in which the roots are situated or trying to move, is dry, than in winter, when it is moist—not waterlogged, but moist enough for absorption, while at the same time permitting of free percolation, for where water passes through the soil air follows, and there can then be no stagnation. The earth, then, to be in the best condition for the reception of liquid manure, must be moist, yet sufficiently drained naturally or artificially.

During the summer months and at the present moment the earth may appear moist, and is moist, it may be, to a foot or so in depth, even under and near long planted, large, yet enfeebled trees; but below the moist layer in which there are few or no roots, we find on digging the earth is as dry as powder, and it is in this dry under stratum that the chief of the roots are established. This should be thoroughly moistened with clean water, then, and not till then, following with liquid manure. But it is often most difficult, and may be impracticable, to make the impoverished soil moist at this season of the year, in which the roots of starving trees are established; and beyond question the autumn rains and winter snows do the important work more effectively and cost nothing. Then is the time to empty cesspools and pour the contents into the ground; of course, when the surface is in a moderately dry state. At that season of the year the liquid can be given of twice the strength it would be safe to apply it when the roots are in an active state; in fact, it is not easy, I suspect, to give it too strong in winter. Some of the virtues may pass away, but the bulk will be retained by the moist soil, and be imbibed by the roots to the certain benefit of the trees.

I have used thousands of gallons of the contents of cesspools that could only be emptied in winter with the most striking benefit

to all kinds of fruit trees and bushes which only needed sustenance to render them bearers of excellent fruit; as I gained courage from experience the liquid was less and less diluted, and the stronger it was the more marked was the effect beneficially on the trees. If the soil is moist now liquid manure may be given with advantage to fruit trees that obviously need support; but the very strong may need to be somewhat diluted. It is worse than useless applying it to dry soil, as it drains down, leaving little of its virtues behind, and may in passing do injury to some of the roots; but apart from that the practice is wasteful, and therefore should be avoided.

When travelling in Lincolnshire in August I had the pleasure of calling on an ardent gardener and Journal reader, a clergyman and son of the late Canon Hodgson of Hythe. I had known the old espalier and other trees in his garden for years. Many of them had the appearance of being worn out, and most persons of an improving turn of mind, with the means of carrying out their ideas, would have destroyed the old trees and planted young. Some were planted but the old were retained and nourished. I was somewhat astonished to see the change they had undergone since last year, thick deep green leaves in place of the pale and thin; stout short jointed, well-fed wood in place of the weak; large fruit in place of the small, clear and rosy in place of the speckled and sickly hued. This rapid renovation had been effected by liquid manure given strong and plentifully in the winter.

I had exactly similar experience in years gone by, and in the same village. Whether the vicar came to hear of this I know not, or whether he remembered something he had read on the subject, or whether it was a question of wasting the sewage or not, and so he ventured to try it on the old trees, not minding much if he cooked them, I am not able to say, but the fact remains he did pour the strong stuff into the ground when it was naturally wet in winter and the trees leafless, then when the spring came and the summer advanced the sturdy shoots and thick dark leaves, the bold buds, and good fruit told plainly that the food in solution given in winter when the trees were resting was not lost, but retained and appropriated. In no other way could the enfeebled trees have been improved so quickly, decidedly, and cheaply.

It is nearly thirty years since some cesspools on the premises of a gentleman could only be emptied in the winter. The contents were applied to old trees in an orchard, completely saturating the ground, and there was no mistaking the effect of the application. It was then used in the garden, being given to trees of various kinds near walls and in the open that appeared to need extra support; also to Gooseberries, Currants, Strawberry beds, and Raspberry plantations, with the most satisfactory results; indeed, for seven years they had no manure beyond the sewage, and this was only given in winter. The owner of the trees and bushes, and all else who knew them, were satisfied that they became much more healthy and grew far better crops of fruit after being thus treated than they had ever done before, and canker wounds healed freely in some apparently worn out Apple trees that were invigorated in the manner described. To be effectual the application must be thorough, surface dribblings being of little use.—J. WRIGHT.

CHINA ASTERS.

For garden decoration, to yield a supply of flowers, as plants in pots, and for exhibition, few annuals can approach these in usefulness and beauty. They come at a season when many other plants in the flower garden are rapidly losing their attractions; the more fragile annuals provided for an early summer display are usually over, especially if the weather has been hot and dry, and where successional sowings have not been made to provide for the later season flowers are becoming scarce. China Asters have many admirers, and at most of the early autumn horticultural shows

classes and prizes are provided that bring a fair number of exhibitors, yet the plants have not the same popularity they had some years ago, notwithstanding the attention paid to them by cultivators and seed growers, who have greatly improved and diversified the strains or varieties. Large quantities of seed are annually saved in the grounds of the continental growers, especially in the German farms, where so many annuals are grown for seed, which ripens readily under a clearer summer sky and in a higher temperature than those distinguishing our insular climate. All our leading seedsmen have special prize strains with which their respective names are identified; elaborate illustrations appear in the catalogues, and still we do not often see either in gardens or at shows anything approaching to an extensive display, or an adequate representation of their cultural value; yet the seed is cheap, the plants are easily grown, and they do not require much space under glass. At Chiswick this year, as noted last week, a large collection has been grown for trial, the beds and lines of differently coloured varieties constituting a brilliant Aster exhibition, which has awakened the admiration of such visitors as find their way to the gardens at this time of year. It also afforded the opportunity of comparing the different types and groups, and even gave some idea of the advance that has been made with these plants, for while there were some flowers of very high quality there were others but little superior to some of the earliest forms obtained. This shows what care is still requisite to maintain the character of varieties or strains, for though it is easy by continued selection to fix these so that a large percentage come true to colour and character, yet a season's neglect is quite sufficient to upset the work of many years. It is not difficult to induce variation in numbers of plants, but the fixture of the characters obtained is quite a different matter, and the most skilful hybridists find more trouble in this than in any other respect.

The plant with its innumerable varieties popularly known as the China Aster is interesting in several ways, both historically and structurally. In the first place all the diverse forms in cultivation at the present time are the produce of one species, *Callistephus chinensis*, also known to the older writers as *Aster chinensis* and *Callistema hortensis*, and it constitutes one of the best examples of specific variation without the aid of intercrossing with other species that can be named. Then it is quite clear that, in China at least, and perhaps too in Japan, this *Callistephus* has been grown for a long period, and it has often occurred to me that the so-called "blue Chrysanthemum" which has been thought to be an imaginary flower may really be a blue Aster, some of the flat forms of which are much like a reflexed Chrysanthemum. That a blue Aster was long known is evident from the fact this was one of the three colours distinguishing the varieties first introduced to Europe. It appears that some of the missionaries sent seed to France, and d'Incarville is credited with having been the original introducer; at all events the plant had not been long grown in Paris gardens before some seeds were sent to Philip Miller at Chelsea, who has recorded that he first received them in 1731. From these plants were raised with red and white flowers, but five years later seed of the blue variety was obtained; they were all single, and it is rather curious that sixteen years elapsed before seeds of the double red and blue varieties were secured, the double white following in the succeeding year (1753) from Dr. Job Baster of Zirkzee. It is not quite clear whether these double varieties were wholly the result of culture in Europe, but it is probable that several consignments of seed were received from China, and it is quite likely these were found in some of the later supplies. In France, however, the China Aster, or "La Reine Marguerite," as it was there termed soon became a favourite, and was largely grown some time before it attained much popularity here. It was grown at Kew in 1789, but Aiton does not mention any varieties. At the beginning of the present century, however, Martyn states that "besides white, blue, purple, and red, both single and double, there is now another with variegated blue and white flowers." In 1826 Sweet enumerated the following varieties:—*cœrulea*, *rubra*, *alba*, *variegata*, *multiplex* (double), and *brachyantha* (bonnet), which seem to be the same as those already mentioned, with botanical names, except the last one, of which I have not found a description. Possibly it refers to a variety of the type with the central and outer florets of different colours; it can scarcely be the quilled variety that was introduced a few years later. M. C. Bailly's "Manuel Complet du Jardinier" was published in Paris in 1829, and in it he divides Les Reines Marguerites into three groups or varieties. 1, Marguerite double, double Asters; 2, Marguerite naine hâtive, dwarf early Asters; and 3, Marguerite à tuyaux ou Anémone, quilled Asters. He does not say when the last named appeared, but it seems that they were of French origin, though now it is common to style the quilled varieties German and those with flat florets French Asters. This was a very important break; the earliest introduced forms had the usual so-called single blooms of

wild members of the Compositæ family—namely, small central tubular yellow florets and flat outer or ray florets. In the process of "doubling" under cultivation the ray florets were increased at the expense of the central florets, so that the perfect double bloom of the florist consisted entirely of flat florets more or less symmetrically arranged in an imbricated manner. The reverse had taken place in the production of the quilled varieties, the tubular florets being much more largely developed, becoming variously coloured, and either excluding all the other forms of florets or leaving only an outer marginal row termed "guard petals." This change was so great from the other type that it must have taken a considerable time to effect, but as the China Aster had been grown in France for at least a hundred years when this quilled variety was announced by Bailly it is quite likely to have been obtained by a long course of selection. This variety was soon introduced to England, for Phillips in 1829 records the appearance of one "consisting entirely of quilled florets."

From this time onwards increasing attention was paid to raising these Asters from seed on the Continent, and there is no doubt that most of the distinct types and numerous bright, soft, and beautiful colours are due to the efforts of French and German seed growers, and from them we still obtain the bulk of the seed used in this country. Attempts have, however, been made to raise seed on a large scale here, and one of these experiments, which for a long period proved exceptionally successful, and resulted in a wonderful improvement of the beautiful quilled varieties, was that conducted by Mr. Betteridge at the Aster Nurseries, Chipping Norton. For over thirty years Asters were largely grown there, the commencement being made in the spring of 1845, when a pinch of seed was purchased of Butler & McCulloch in Covent Garden, and from the plants then raised the best were selected, the process being repeated year after year, but for ten years Mr. Betteridge has said little progress was made. After that time results became more satisfactory, and in the next twenty years upwards of fifty distinct and good varieties were raised, a large proportion being certificated at the Crystal Palace and provincial shows. Special attention was paid to the quilled type, and some charming forms were secured in the group remarkable alike for their high quality as viewed from a florist's standpoint and for the diversity of colours. In 1873 four excellent varieties were sent out by Messrs. Sutton & Sons of Reading, and in the following year Messrs. J. Carter & Co., High Holborn, purchased the whole of the seed of the current year. In the four succeeding years many other improved varieties were certificated and sent out, then several unfavourable seasons occurred for harvesting seed, and one of the last of this strain that was brought into prominent notice was Fair Rosamond, a beautiful variety with pure white central florets and dark purple guard florets, which appeared in 1881. At one time as many as 120,000 plants were grown at Chipping Norton for seed, and the effect produced by long beds 4 feet wide planted with differently coloured varieties can be imagined, but the uncertainty of our climate renders seed-saving somewhat precarious, particularly when it cannot be harvested before autumn, and this no doubt ultimately rendered Aster culture unprofitable.

It is a curious fact that amongst the many hundreds of plants for which the Floral Committee of the Royal Horticultural Society have awarded certificates since 1859 only two China Asters have been honoured—namely, Unique (Gilkes, 1876) and Dark Scarlet (Benary, 1886), until the meeting at Chiswick on September 5th of this year, when the certificates adjudged for varieties tried in the gardens may be considered as of more comparative than absolute value, though regard is paid in such selections to the individual merit of the varieties distinguished. This was the third Aster trial at Chiswick, for in 1877 an extensive comparison of varieties and strains took place when seed was received from Messrs. Carter & Co., E. G. Henderson, Wheeler & Son, Vilmorin et Cie, Dippe Bros., Haage and Schmidt, R. Dean, and Benary. Thirty-two types were tested, and in the result the following groups and characters, slightly modified to agree with present types, were adopted under which they were arranged, several of these being in twelve distinct shades of colour.

Chrysanthemum-flowered Asters.—Flowers mostly large, often exceeding 4 inches in diameter. Florets broad, flat, sometimes recurved, so as to raise the centre. Plants of compact growth, 9 to 12 inches high, slightly branching; blooms on erect strong stems.

Victoria Asters.—Taller forms of the above type.

Emperor Asters.—Blooms large, florets broad, flat, and resembling the Chrysanthemum section. Plants seldom branching, a single bloom being borne on each stem. Robust growth.

Pæony-flowered Asters.—Blooms large and full, florets broad and incurved, forming in the best examples globular blooms 3 to 4 inches in diameter. Plants 18 to 24 inches high, slightly branched and free.

Globe Asters.—Intermediate between the Chrysanthemum and

Pæony-flowered; blooms large, but often rough and rather drooping. Plants 15 to 18 inches high.

Pompon Asters.—Blooms of medium size, neat, and close; the outer florets flat, the inner quilled. Plants compact, branching, habit free; height 12 to 15 inches.

Bouquet Asters.—Blooms of medium size, 2 to 2½ inches in diameter. Plants small, compact, 6 to 7 inches high; free.

Shakespeare Asters.—Blooms small, early. Plants dwarf, 4 to 6 inches high.

Honeycomb Asters.—Blooms large, flat; florets tubular at the base, but flat at the top. Plants of medium growth.

Needle or Hedgehog Asters.—Blooms large, flat; florets tubular and close pointed. Plants of medium growth, 15 to 18 inches; free.

Quilled Asters.—Blooms drooping, somewhat globular, even, and regular, 2 to 3 inches in diameter. Central florets regularly quilled, with an even five-lobed limb; outer florets flat. Plants tall, straggling, 2 to 2½ feet high. Late. Useful for cutting.

In 1888 a trial of Asters was undertaken at Chiswick, when Messrs. Benary, Vilmorin, Dobbie & Co., and others contributed seed. The varieties were grouped under seventeen classes, including most of the preceding with a few others. The very distinct variety Comet was grown on this occasion; it is one of the Chrysanthemum-flowered type, with flat florets, white edged with rose.

Under some of the preceding most of the new varieties now grown can be readily grouped, but at the trial this season a few fresh types have been introduced. Some of the best of these are as follows:—

Imbricated Pompons, with regularly formed blooms, the florets imbricated, dwarf, and compact, not exceeding 12 inches in height; the colours varied, rich, and distinct. **New Liliput.**—Blooms of good shape, quilled, some with light guard florets, and rose centre; others with crimson centre or white; plants dwarf, 9 to 12 inches high, free, and useful for pot culture. **Victoria Needle.**—Blooms closely quilled, the tubular florets narrow, even, forming a fine semi-globular head, crimson, and purple shades good. **Coeur-deau or Crown.**—This is not a new type, but an excellent strain was grown, the blooms variously coloured with white centres. Height 20 inches. **Dwarf Pyramidal.**—Blooms varied in colour, of good shape, compact, free, and even in habit; 12 inches high. It may be added that some of the very dwarf varieties are most unsatisfactory, usually irregular in habit, and with blooms of little substance. The best blooms are produced by the tall or medium height varieties, and for cutting purposes these are useful. The so-called bouquet Asters are not so good as the others, the blooms coming in a bunched form, and losing their individual characters. Most of the strains are offered by seedsmen in distinct colours, but the mixed strains are now so carefully selected and so reliable that all the best shades are obtained from a packet of mixed seed.

In the culture of China Asters the most important point is to ensure having sturdy plants for placing out of doors, as weaklings will never give satisfactory returns. The seed is often sown in heat; at one time this was the general practice, but a better plan is to sow the seed in pans of light soil, and place these in cold frames about the first or second week in April. Mr. Betteridge used to sow the seed in drills in cold frames, subsequently pricking out the young plants a foot apart in similar frames. The seedlings are usually large enough for transferring to other frames or beds in a fortnight or three weeks from sowing, and they can be transferred to the beds out of doors as soon as they have made good progress and the weather is favourable. They require a rich well-dug soil and frequent supplies of water in dry weather; but in their early stages when under glass care must be exercised in watering, as in common with many other plants they are very liable to damp off in a young state. In the beds a foot to 18 inches between the plants and rows is sufficient, the small-growing sorts requiring less space. Exhibitors usually shade their blooms with some light material, and thin them to about half a dozen to each plant. For pots plants can be grown in the same way, lifting and transferring them to pots early in September, as if well shaded and watered they suffer but little if care be taken to preserve the roots. These plants are useful in conservatories and greenhouses during October, and often indeed until the November-flowering Chrysanthemums are at their best when Asters are no longer required.—L. CASTLE.

TREATMENT OF SOILS AND MANURES.

As Mr. Bishop's second article, page 173, on the above subject is more confused, if possible, than the first, many of the sentences being unintelligible, I shall limit myself to a reply to his last communication, page 229. I am sorry to have offended him by quoting an old Latin adage, which certainly does not directly refer to manures or cultivation, but nevertheless gives, metaphorically, very good advice to anyone, however skilled he may be in his own

business, who attempts to advise others on subjects as to which he is unable to measure his own ignorance. I translate the adage for the benefit of Mr. Bishop, "Let not the cobbler go beyond his last."

It is difficult to discuss a question with Mr. Bishop because he repudiates all authorities, and sets his own experience against that of the scientific world. Although I have cultivated plants for about sixty years, during fifty of which I used only stable manure, yet I think it possible that others who have made the study of plants and their food the business of their life may have something to teach me, and acknowledge their authority, consider myself quite justified in quoting them even when they are antagonistic to one so experienced as Mr. Bishop.

Mr. Bishop denies that carbonic acid and carbon dioxide are the same, and asserts that the formula of the former is H_2CO_3 , and of the latter CO_2 . He must be a phenomenal genius if he evolved out of his own experience the formula H_2CO_3 for carbonic acid; but as this is scarcely credible I must assume that in this case he condescended to consult some books on chemistry. It was reasonable to believe, as he was addressing gardeners "who were not scientific," that he would use terms according to their popular acceptance. "Chambers' Encyclopædia," a popular authority, states that carbonic acid is a substance occurring free as a gas in the atmosphere, &c., with the formula CO_2 , and nothing whatever of the hypothetical carbonic acid with the formula H_2CO_3 , while Watts in the "Dictionary of Chemistry," a scientific authority, states, "Two oxides of carbon are known, the protoxide CO and the dioxide CO_2 , commonly called carbonic acid;" but in another paragraph, that water in which gaseous carbonic anhydride (CO_2) is dissolved possesses acid properties, from which it may be inferred that it contains an acid of the composition H_2CO_3 , but this acid cannot be isolated, and as a definite compound cannot be said to be known. Mr. Bishop must have very minutely searched the authorities, notwithstanding his want of faith in them, to have discovered this mysterious H_2CO_3 , which very few have heard of, and no one has caught. I must have others to decide which of the two, Sachs or Mr. Bishop, is the more trustworthy authority as to the source of carbon in plants. If the latter had known anything of the law of the diffusion of gases, familiar to every tyro in chemistry, he would not have committed himself to the nonsense of asserting that by the wise provision of Nature the carbon dioxide falls to the ground because of its greater weight. If it were so animal life could not exist on the surface of the earth, as the stratum of air then would consist mainly or entirely of carbonic acid. I recommend to him the very simple test of filling two jars with carbon dioxide and air respectively, and then superimposing mouth to mouth, the jar containing the air upon that filled with carbon dioxide, he will find that in a short time the heavier gas in the lower vessel ascends and displaces the lighter air in the upper vessel, while the lighter air descends into the lower vessel until the two gases are evenly distributed in both.

Mr. Bishop states it to be pure assumption on my part "to suppose that carbon is taken into the plant in this form (what form?) and thrown off without being utilised." The sentence is unintelligible, and certainly does not express anything written by me. I suppose he refers to my quotation from Sachs; if so, the assumption is not mine, and, further, he misreads Sachs, who states that "the enormous quantity of carbon, about half of the whole substance of the dried plant, is derived from the carbon dioxide of the air." Where have I stated that the carbon was "thrown off without being utilised?" What more real utilisation could there be than for the assimilation of the carbon by the plant? As the whole of the carbon of the plant was accounted for by Sachs, the "other half" exists only in the imagination of Mr. Bishop. I pointed out the absence in Mr. Bishop's original communication of phosphorus from "his four principal elements necessary for plant growth," he now informs us that "he had stated six organic elements to which phosphorus belongs," from which it may be observed that in his opinion phosphorus, carbon, nitrogen, sulphur, oxygen, and hydrogen are organic elements. What does he mean by this term? An organic element is something unknown to me; perhaps he will enlighten my ignorance, which supposed the usual division of the elements to be into metallic and non-metallic, or into metals and metalloids.

I have again to complain of Mr. Bishop's misquotation. I did not say that "hundreds of thousands of pounds are spent on phosphorus when nothing is spent on potassium, magnesium, calcium, and iron for manure." The latter half of the sentence should read "comparatively little on magnesium and iron." It would have been absurd to say that nothing was spent on potassium when very large sums are annually expended on kainit, potassic sulphate, chloride, and nitrate, &c.

Mr. Bishop denies that he said stable manure was very uncertain. His actual words are, "There is ten times more nitrogen

in manure that has been properly prepared than when neglected. If left long exposed most of the more valuable elements escape, and removing such manure to the land is like taking your purse to the bank with no money in it. How many think of this? Is not this an admission that stable manure as usually applied to the land is very uncertain?

I am well aware of the great value of stable manure and of its abundance and cheapness in London, which may explain why so little artificial is used in proximity to the metropolis; but the country generally has not a supply either so abundant or cheap, consequently there artificial manure is much more economical, for it is far from exaggeration to assert that 1 cwt. of a properly compounded artificial manure is more than equivalent to 2 tons of the best stable manure; it produces as good or better crops and does not impoverish the land. The vulgar error as to impoverishment originated from the improper use of nitrogenous manures, such as sulphate of ammonia and nitrate of soda by themselves; even when so used they impoverish the soil only in the sense that they enable what is in it to be taken out in a shorter time. No land can be cropped continually without impoverishment if the phosphorus, potash, &c., taken away in the crops be not restored to it. If phosphorus, potash, &c., had been added to the nitrogenous manures there would have been no complaint of impoverishment.—EDMUND TONKS.

THE ORCHID ALBUM.

THE eighth volume of Mr. B. S. Williams' Orchid Album is just completed, and contains forty-eight excellent coloured plates of even more varied character than the preceding volumes. Twenty-seven genera are represented, some of the largest having several plates each; thus there are four *Cattleyas*, six *Cypripediums*, four *Laelias*, six *Odontoglossums* and four *Oncidium*s. The illustration of *Odontoglossum Harryanum* is a good one, but that in which *Odontoglossum eugenes* is depicted is exceptionally beautiful. The colouring in all has been very carefully done and the plants are faithfully represented. The descriptive and cultural notes are full, practical, and useful.

DENDROBIUMS.

As these complete their growth it is important more light and air be admitted to the plants to barden and ripen their pseudo-bulbs. Frequently they are kept after they have lengthened out their growths in too close and too moist an atmosphere, which has the effect of starting them again into growth. This is not all, for the foliage often commences dying towards the tips prematurely. This is unnatural, and should be prevented. Plants that lose their foliage in the manner indicated seldom mature their pseudo-bulbs as thoroughly as they ought to do. Retain the leaves upon the plants until they assume a ripened hue, and then turn yellow and die away naturally. Evergreen species are often seriously disfigured by half of their foliage dying away through being grown in an atmosphere that is overshadowed and nearly at the point of saturation. The moist atmosphere and liberal supplies of water that these plants need during active growth have in many cases led to excess. In all cases where growth is complete and ripening has commenced do not withhold water suddenly so as to check them, let the supply be gradually diminished, and the same care should be taken in giving them a lower temperature. Plants of *D. crassinode* that have been grown in a moderately light dry structure have made thick firm growths 18 inches to 2 feet long, and are now being fully exposed to the sun in a cool house where air is admitted abundantly during the day. *D. Wardianum* we are exposing in vineries for the present, where the foliage is thin and light can penetrate freely to the plants. *D. nobile* and its forms are standing on a moisture-holding base in the greenhouse fully exposed—that is, all that have completed their growth.

Such species as *D. moschatum*, *D. Calceolus*, and other strong growers require thorough ripening, and in order to accomplish this they must be freely exposed as early in the season as possible—directly, in fact, that they have lengthened out their growths and attain a little solidity. The free-growing *D. chrysanthum* is charming when well and profusely flowered, but when subject, as is too frequently the case, to stove treatment the whole year through, the flowers are few in number in comparison with plants that are given distinct seasons of growth and rest. When kept in the stove

this plant is almost a perpetual grower, and increases rapidly, but its growths soon become thin and puny. There are two distinct forms of this plant, the one having longer and thicker pseudo-bulbs than the other, and flowers for 18 inches or more of its length. The flowers are the same. The stronger grower is deciduous, while the other under the same treatment retains a portion of its foliage. The one shows its flowers as soon as the growth attains a fair amount of solidity, the other not until it is ripened and has lost its foliage. Where growth is completed give the plants the same treatment as *D. Wardianum*, and prepare them for a thorough season of rest.—ORCHID GROWER.

IN THE MIDLANDS.

SMITHS' OF WORCESTER.

So familiar is the above designation of a famous nursery, and so naturally does it come to the lips and the pen, that the "precisely proper" may stand aside for once, and the popularly expressive take its place for the purpose of this brief description. No one, presumably, who is interested in horticulture, and having an hour to spare in the historic city, would fail to run down by tram or otherwise to the great and diversified nurseries of Messrs. Richard Smith & Co. at St. John's. Those who have been before will be ready to go again and be gratified, while those who have not yet had the privilege of seeing what is to be seen there may make up their minds to be astonished. It is not too much to say that "Smiths' of Worcester" is one of the great nurseries of the world, and its owners rank amongst the most enterprising; indeed, it is a combination of enterprise with excellence that has made the business what it is to-day.

On intimating to a leading gardener in the Midlands my intention of calling at Worcester, he at once said, "Certainly you should not leave the county without seeing Smiths'; it is a splendid nursery, as much like a gentleman's garden and pleasure ground as a trade establishment, in respect to its cleanliness, order, and the high culture displayed everywhere." I found the description correct. Under glass and outside, in the plant, evergreen, deciduous tree, and shrub departments; in the extensive acreage devoted to fruit trees, Roses, and Dahlias, all was alike satisfying, from whatever point of view regarded.

"I suppose you do not want to go all over the nursery," observed the courteous attendant, quickly adding, "you can if you like, you know; but I fear you would find it fatiguing." No doubt he was right. The central walk flanked with borders of choice evergreens is, I think, more than a mile and a half long, and there are dozens of parallel paths, and dozens more of cross sectional alleys for passing between the trees, making in the aggregate forty-two miles of walks that traverse the 200 acres of the enclosure.

And yet within the present century the foundation of the gigantic business was laid in a plot of four or five acres. Now about the same extent of ground is occupied with low pits and frames, in which small choice evergreens are raised and established in pots in scores of thousands—Ivies, *Euonymuses*, *Elæagnuses*, *Hollies*, *Aucubas*, rare *Conifers*, *Acacias*, *Libonias*, *Choisyas*, *Rhododendrons*, *Azaleas*, *Clematisses*, and various others, all "sized," so to say, and attractive by their freshness and uniformity. Then there are the houses, thirty of them, one being nearly 400 feet long, and one or other of them containing plants of every description in demand in gardens. It is evidently a great plant-manufactory, reminding in some respects of the Belgian establishments, but far larger, and in every way better than the great majority of them. A glance suffices to show the superiority of the *Azaleas* and *Camellias* to the pampered and fed-for-sale continental plants, which can scarcely be kept alive after the first season, while the home-raised and differently grown, with fair treatment, go on improving, and are decidedly the cheaper in the end. This purchasers appear to be finding out, for the demand is ever increasing.

Amongst other plants which catch the eye in passing are some hundreds if not thousands of *Pimelca spectabilis rosea*—models in health and symmetry, a houseful of that not easy to raise plant *Phenocoma prolifera Barnesi*, a great block of *Libonia Penrhosiensis* which places the more familiar *L. floribunda* quite in the background, a similar bank of *Statice Butcheri*, decidedly one of the best of the genus and of greenhouse plants; a houseful of seedling *Lapagerias*, several distinctly meritorious; numbers of the bright yellow *Cassia corymbosa*, flowering in 5-inch pots; and in contrast a splendid collection of Ferns, including a houseful of *Adiantum farleyense*, but not a houseful of the recently certificated *Pteris tremula Smithiana*, with its crested fronds, which we may be sure will be increased as rapidly as possible, and no doubt wanted as fast as it can be provided; a number of plants of the free and elegant *Asparagus comorensis*, an advance on *A. plumosus nanus*. Such are some of the plants that arrest attention under glass, but not less so perhaps than the 6000 Vines in pots that will soon be ready for distribution.

But large as are the stocks of different kinds of plants in pots that are in chief demand, the chiefest are the *Clematisses*. Surely this must be the great emporium of these handsomest of hardy climbers. The majority are plunged over the rims of the pots in the open quarters, sturdy, hardy, ready for delivery and planting. Whence such numbers go every year is a marvel, but they do go. Thousands are already sold, and only await the condition and time when they can best be despatched to the purchasers. Numbers smaller are coming on, and amongst those

under glass is a variety regarded with extraordinary solicitude—a real genuine white form of *C. Jackmanni*, exactly similar to the type in character, and equal to it in freedom of growth and floriferousness—a true and good companion long sought for of the old favourite, and not hitherto found as possessing the coveted characteristics. Plants in small 48-size pots were bearing from fifteen to seventeen blooms, and budding at every joint produced. The new variety is not yet named, and it is hopeless for anyone to expect plants at present. Many thousands will doubtless be raised before one is sold, for offering it until the stock is very large could only end in disappointment. There are plenty of others, however, of all the best varieties in commerce, the stock amounting to 100,000 plants.

Now we pass quickly down the nursery, and find something of interest on every hand. Here are Tea Roses in pots flowering freely and in great variety, and there are twenty acres of all sorts planted out. Now we come to bright rows of golden Lilac, and next to bluish silvery masses of *Pinus nobilis glauca*; then acres of the sombre Austrian Pine, of which they "cannot get too many," relieved with *Cedrus atlantica glauca*, a particularly fine form, for they vary, and thrifty young trees of *C. Deodara alba spica*, distinct in hue from all other varieties of this elegant Conifer. Next we came to large "breaks" of Laurels, the *colchica* variety being in great demand, since "rabbits eat all others but leave this alone"—a hint for persons who are planting evergreens where these voracious animals abound. And so we may go on picking up hints and admiring scores of things till the memory becomes overlaid; but a golden mass of *Hypericum* cannot be forgotten, including the densely flowered *H. prolificum*, and the free flowering and red fruiting *H. cypripedium* and *H. elatum*, which are so effective for mounds and rockeries.

The nursery is particularly rich in ornamental trees, some remarkable for their enormous green leaves, such as the Balsam Poplars, others for their striking colours—the purple *Prunus Pissardi*, and the bright golden heads of *Ulmus Dampieri aurea*, the dark bold leaved *Acer Schwedleri*, one of the finest of trees, with the upright growing *Populus Bolleni*, nearly as close as a Lombardy, and the under sides of the leaves silvery white; while gold and silver Sycamores are not excelled in clearness and marking by any tropical plants that are grown in stoves. Judiciously arranged, such trees as those mentioned, and many more, are capable of imparting beauty to, that is now absent from, many pleasure grounds and home plantations.

There yet remain the fruit trees, 74 acres of them, that will bear inspection, and are worthy of it. The popular varieties have to be provided in great numbers to meet the yearly demand, and nowhere can we better learn which are the most popular than in a nursery like this. Taking Apples, we find on inquiry that Ecklinville Seedling has come quite to the front, now equalling Lord Suffield with a sale of 6000, while Worcestershire Pearmain, Cox's Orange Pippin, Stirling Castle, Golden Winter Pearmain (the correct name of the variety known as King of the Pippins), Warner's King, and Blenheim Orange are only each 1000 less; Keswick Codlin, Irish Peach, and Dumelow's Seedling next following with 2000 to 3000 each. Victoria heads the poll amongst Plums with between 4000 and 5000, the next most in demand being the Early Prolific, Czar, Kirke's, Pond's Seedling, Cox's Emperor, Jefferson's, Prince Englebert, and White Magnum Bonum with 2000 to 3000 each. The same number of the following Pears are required—namely, Williams' Bon Chrétien, Souvenir du Congrès, Jargonelle, Louise Bonne of Jersey, Marie Louise, Pitmaston Duchess, and Winter Nelis. There is an equal demand for May Duke, Morello, Bigarreau, Black Heart, and Governor Wood Cherries. Amongst bush fruits it is remarkable the distinct lead Woburn's Industry has taken amongst Gooseberries, the annual sale being 50,000; Crown Bob, Lancashire Lad, Whitesmith, and Ashton Red not exceeding 4000 each, the same numbers being required of the Champion, Naples, and Lee's Prolific Black Currants; also of Red Grape and Victoria, the White Grape also being in great demand. It is satisfactory to find the fruit-growing public judging so well in the selection of varieties, and it can only be a question of time, and not a very long time either, when the supply of home-grown fruit must be greatly improved.

A feature of interest to many must be noted amongst the fruit trees. In a quarter of young Apples seeds of Mistletoe had been attached to the base of the branches; how and when I cannot say, and my guide "could not tell me," and I did not expect he would if he could, as perhaps he might if he had tried. It was his business not to try, and it is mine to record that Mistletoe trees will soon be plentiful, for hundreds of seeds were germinating freely, and healthy growths were extending, some of them with a pair or two of leaves, others more. Last year a standard Mistletoe bush was figured in the Journal as grown by Mr. Van Geert at Antwerp on the Thorn. Similar trees, but on taller stems of Apples, are in fair progress at Worcester, and when ready for removal there is not the least doubt there will be plenty of people ready and even anxious to possess them. The culture of the interesting parasite in the nursery bids fair to be very successful.

Time flies and space vanishes, and it can only be said that 5 acres of ground are devoted to herbaceous plants, and apparently about the same to Dahlias. They were in splendid bloom and great variety, brightening as no other flowers can gardens and pleasure grounds in the autumn months. Yes, a little more can be said, has been said, and may be said again in better terms than I could choose. A *ci-devant* correspondent of the Journal once visited Worcester—the learned and genial "Wiltshire Rector," who after saying what he had to say on gardening, devoted his attention to pigeons and birds. May they long afford him

pleasure and be delight to others. His concluding words in describing his visit shall be the concluding words here, for they are good and true—"St. John's Nursery is an indirect proof of the prosperity and refinement of the English people of this day. In war and in rude times men had no leisure or care, or even thought, for ornamenting their parks, shrubberies, and gardens. There might be an exception here and there, as in John Evelyn, but there are hundreds of John Evelyns now—men, aye! and women in abundance, who delight in the beautiful in tree and shrub, and who lovingly regard the form and colour of leaf and flower. Gardening best prospers in quiet times, as now in England. Long may they last. I can only say that St. John's nursery is, as I had been informed, 'a marvellous place,' and as seeing is believing, now I believe, and must add, far from being over-praised, it was the opposite." There is the justification for my foregoing remarks, and my last words are words of acknowledgment, justly due to principal and officials for making the short time a pleasant time as spent in the famous establishment.—W.

ATHANASIA ANNUA.

SEVERAL shrubby evergreen species of the genus *Athanasia*, natives of South Africa, are known, and occasionally but rarely they are seen

FIG. 32.—ATHANASIA ANNUA.

in greenhouses where collections of scarce or interesting plants are grown. One *Athanasia*, however—that named above—is of annual duration only, and was at one time a rather familiar occupant of English gardens. It is a native of North Africa, chiefly in Barbary, and succeeds out of doors in this climate during the spring and summer months. The whole plant is rather fleshy in structure, like many other members of the Compositæ. The leaves are pinnatifid, and the florets tubular in close fleshy heads, these again being clustered in dense corymbs suggestive of some of *Achilleas*, especially *A. aegyptiaca*, but the individual heads are more prominent, and the corymbs are consequently not so flat. When cut the flower heads last for a great time in water, and even when

cut and placed in a cool position they remain fresh for more than a week out of water. The plant succeeds in any light well drained soil, and is raised from seed sown in early spring.

RHUBARB.

BEFORE the growing season closes I think I had better work off my remaining notes on Rhubarb. In April I had something to say about a few varieties of Rhubarb, and chiefly of early Rhubarb, and my dissatisfaction at the apparent confusion there was in the nomenclature of those early Rhubarbs. By the kindness of the Editor I was made the happy possessor of "Handy Andy's" variety, Tokolsk, and, later on, of the true early Chiswick Red from Mr. A. F. Barron of the Royal Horticultural Society's Gardens. In the course of the summer I had also a variety of Early Red sent to me by Mr. Lister of Darnall, who grows Rhubarb largely for the Sheffield market. Just lately I have introduced into my garden the Vicar of Yaxley's early Rhubarb; so that, by comparing these varieties one with another, as they are growing together all in one garden in relative positions in our central midland neighbourhood, and that if we are spared over one or two or three seasons, I ought to be able to get a little light on the much-vexed questions, as (first) which is the earliest variety grown? and (second) what is the correct name of that variety? with other kindred matters.

If I could I might turn my place largely into a trial ground for Rhubarbs, for those of my neighbours, some near and some distant, who have been raising seedling Rhubarbs, now and in the past, are anxious that I should have specimens of their best that I may compare them with other varieties. As my space is limited and my garden demands heavy and continuous, I am obliged to decline their very kind offers. What I say to them in part, in reply to their generous offers, I think I ought to say here, because I consider it is whatever Rhubarb raiser and grower ought to study closely. In these, or like words, I say, "As nearly every quality desired in Rhubarbs is in some one or other of present day varieties, especially size, colour, substance, and flavour, the attention of all Rhubarb raisers should now be given to the very important point of earliness." The raiser who produces a variety which will add a week, or a day even, to the production of natural Rhubarb will do good to his profession, the people at large, and, let us hope, bring a substantial recompense to himself. Earliness then, combined with present good qualities is the great desideratum.

In my notes in the *Journal of Horticulture* of April 4th, page 270, I mentioned a variety of Rhubarb much like Hawkes's Champagne, which had been submitted to me for trial by Mr. Lister of Darnall, and which he calls Cherry Red. I said that I should watch it closely and report on it. I have done so, and I can honestly say that as a private establishment Rhubarb it has the finest points, notably the one of flavour, which a Rhubarb can have. Here they are:—1, Earliness; about the earliness of Hawkes's Champagne. 2, Size; medium; greatness of size not desired by good cooks. 3, Substance; crisp and sweet. 4, Colour; brilliant cherry red, and all through. 5, Flavour; none to touch it. With respect to that last and most essential quality for a gentleman's household Rhubarb, I may say that I sent some of it into the kitchen one day when Rhubarb was ordered for stewing, with the request that they would try it, and send me word what they thought of it. The reply next day was, "It was very good; the highest flavoured Rhubarb we have had in; it has rather a lemony flavour." I need not add anything to that, except that a certain housewife who shall be nameless here, though she is the chiefest amongst women, says to her "housebond" one day, "I wish you would let me have some of that Rhubarb which you sent me in the last time, I like the flavour so much." That Rhubarb was Cherry Red. These testimonies settle the matter as to flavour.

Concerning this Rhubarb its raiser, Mr. Lister, has given me a very interesting note on its history, which I will give in his own words. In a letter to me dated May, 1889, he says, "A few years ago I submitted a sample of my seedling Rhubarb to one of the partners of a firm of nurserymen, and after he had tried its quality and pronounced it 'very good' he wished to have a root or two. I sent four roots, so that they might force one or two and grow the others. When the firm had tested its growing qualities they asked me if would sell them a hundred roots, and as I thought it was better adapted for private than for market purposes, and thinking it would introduce it amongst gentlemen's gardeners, I let them have a hundred roots. They wanted a name, and at that time I gave them, what I thought would describe it well, 'Best of All.' The following year, however, they advertised it in their catalogue (as you will see in the copy for 1887, which I send you) at 2s. 6d. per root, under the name of 'Prima Donna, the finest flavoured

variety in cultivation.' I mention this to you, so that if you meet with a Rhubarb called Prima Donna you will know that it is my Best of All, or what I now call Cherry Red."

I will leave until next season, for further consideration, the question of Rhubarb.—N. H. P.

CENTENARY CONFERENCE AND EXHIBITION.

THE programme and schedule have just been issued of the Royal Horticultural Society's Chrysanthemum Conference and Exhibition at Chiswick on November 5th and 6th next, to celebrate the centenary of the introduction of the Chrysanthemum into Europe. It is stated that "the object of the Conference is to get together as large and as representative a collection of Chrysanthemums of all descriptions as possible; to form an exhibition of all subjects pertaining to the Chrysanthemum, whether in its botanical, its horticultural, its literary, or its artistic aspects; and to bring together for the purposes of reciprocal information and fellowship all those interested in the Chrysanthemum and its culture. To carry out these ends the assistance of all lovers of the Chrysanthemum is invited."

A Committee of fifty-four members has been formed, T. B. Haywood, Esq., being the Chairman, and Mr. E. Molyneux the Secretary; the Executive Committee comprising Messrs. A. F. Barron, L. Castle, N. Davis, J. Douglas, Shirley Hibberd, W. Holmes, R. F. Jameson, J. Laing, W. Mease, C. E. Pearson, R. Parker, G. Paul, H. J. Veitch, E. Wills, J. Wright, W. Wildsmith, and Rev. W. Wilks.

The schedule comprises twelve classes for plants, trained specimens, conservatory plants, and groups, the remainder of the thirty-six classes being devoted to cut flowers, new varieties, and appliances for growing and showing Chrysanthemums. The programme of the Conference is as follows, the proceedings to commence each day at 1.30 P.M. First day, Tuesday, November 5th:—1, Opening Address by the Chairman, T. B. Haywood, Esq. 2, Summarised History, by Mr. H. Payne. 3, New Varieties, by Mr. E. Molyneux. 4, Judging Chrysanthemums, by Mr. J. Wright. 5, Progress in Chrysanthemums, by Mr. Shirley Hibberd. Second day, Wednesday, November 6th:—1, Chrysanthemum Seed and Seedlings, by Mr. F. W. Burbidge. 2, Dwarfing and Grouping Chrysanthemums, by Mr. C. Orchard. 3, Market Chrysanthemums, by Mr. C. Pearson. 4, Summer and Early Autumn Chrysanthemums, by Mr. W. Piercy. Schedules can be had on application to the Rev. W. Wilks, 117, Victoria Street, W., or to Mr. E. Molyneux, Swanmore Park Gardens, Bishops Waltham. Forms are also furnished for statistical returns, to be subsequently classified and embodied in the Journal of the Society.

THE NATIONAL CHRYSANTHEMUM SOCIETY.

THE Conference held at St. Stephen's Hall, Westminster, September 11th, and to which we could only allude in a few words last week, was a satisfactory gathering, the papers read and the discussion evoked bringing out many interesting and important facts. Some sixty persons were present, amongst them being Mr. E. Sanderson, Mr. W. Holmes, Mr. W. Piercy, Mr. G. Gordon, Mr. L. Castle, Mr. H. Cannell, Mr. Falconer Jameson, Mr. Harland (Hull), Mr. E. Beckett, Mr. H. Shoemsmith, and Mr. A. Dean.

In the absence of the Chairman and Vice-Chairman of Committees Mr. W. Holmes was requested to take the chair, and he opened the proceedings with a few appropriate words, calling upon Mr. Piercy for the first paper on "Early Flowering Chrysanthemums." This was followed by a communication from Mr. T. Turton, Maiden Erleigh Gardens, Reading, read by Mr. A. Dean, who had seen the collection of early Chrysanthemums in the garden named at the end of August, and had been much impressed by the fine display they afforded. Mr. G. Gordon next contributed a few remarks upon Mr. Piercy's paper, in the course of which he suggested as a means of obtaining brighter-coloured varieties that crosses and seed might be procured between the latest of the late-flowering varieties and the earliest of the early ones. These could probably without much difficulty be had in flower together, and at a time of year when it would be most likely that seed could be procured. He further observed that for seed-bearing purposes it would be advisable to grow the plants in poor soil, so that they might be in a somewhat starved condition. Mr. Cannell remarked that the usefulness of the early Chrysanthemums was not fully recognised yet, and he thought considerable progress would be made in increasing their diversity. He also thought Conferences of this nature afforded an admirable way of bringing together those specially interested in a particular subject, who by discussion could throw light on many difficult points. Several others took part in the discussion, and the Chairman then called upon Mr. J. Doughty, Angley Park Gardens, to read his paper on "The treatment of plants grown for the production of fine blooms a short time previous to the exhibition season." This was followed by some discussion, and

the meeting closed with the usual votes of thanks to the readers of the papers and the chairman.

EARLY-FLOWERING CHRYSANTHEMUMS.

[By W. Piercy, Forest Hill, S.E. Read at the National Chrysanthemum Society's Conference, September 11th, 1889.]

FOR some years before 1876 I was growing Chrysanthemums in the open garden, and I found that very generally just as they were coming into bloom the frost came and spoilt the flowers, often in a single night. I observed that one plant bloomed in October. This was the old sort *Drin Drin*, which set me thinking if it was not possible to have a race of early sorts. I found that very little was known of varieties blooming before November, but in the *Gardeners' Magazine* of November 11th, 1876, a letter appeared from the Rev. F. Freeman, now of Wickersley Rectory, Rotherham, Yorkshire, from which it was evident that he was on the same track as myself. In the issue of the same paper for December 2nd, 1876, there was a communication from the late Henry Taylor, giving a list of thirteen sorts blooming before the end of October. These two communications made me sure that it was possible in England to have Chrysanthemums in bloom in the open before the frost came, and the hunt began. I soon found that Mr. Watson, then of the Marlborough Nursery, Islington, London, grew these plants in large quantities in small pots for trade purposes, but that he had few if any sorts beyond those in Mr. H. Taylor's list, which did not include *Nanum* (the *Sistou* of the French). This came to me in 1877 from the Pine Apple Nursery in the Edgware Road, London, with the name *Nanum*. In 1877, also, I procured *Madame Picol*, or *Piccol*, sometimes spelt *Pecoul*, I do not know which is right. I mention these, not because they were the only varieties, but that they are still two of the best in their respective lines of colour. *Madame Piccol* has since produced a red sport, which is called *Mr. Piercy*, because it first sported at my place. I do not know who raised either of them, but that they came from France there can be little doubt. Some were probably known and grown as early as 1817, for the London Horticultural Society offered a medal for early-flowering Chrysanthemums in that year, but I do not know with what results. Mr. Broome's little book, published in 1858, mentions thirteen sorts. Among these were *Scarlet Gem*, since called *Little Bob*, its proper name being *Dr. Bois Duval*, and *Frédéric Pelé*, which seems to have preserved its French name all through until now. These two are still grown, and *F. Pelé* is even now the best in its line for many purposes, but *Dr. Bois Duval*, although a fine colour and doing well in some places, is a very weak plant and difficult to keep in winter. Mr. Salter, in his book published in 1865, gives a list of fifteen sorts, but I do not know whether *Illustration* was in either of those lists. This was one of the best old sorts, being hardy, robust, of good habit, dwarf, and free-flowering. It has had many names and several sports, and for a considerable time was the principal variety grown. Its proper name is *Marie Longarre*, as I imported it from France so-called. It is still grown by some and is good for rough culture and common flowers. The first I know about it is that it was procured by Mr. Watson of Islington from a churchyard at the West End of London in 1869, and it was the first sort he had. *Précocité* is another old sort still grown for large quantities of cheap yellow cut flowers, and holds its position because it is robust in the open ground, and owing to a slight incurve of the flowers packs and stands carriage well in large bunches. I knew nothing of this before 1877. A few years previous to this most people seemed to know nothing about early-flowering Chrysanthemums; others said they were quite common, but some of the latter were such that if you were to show them a bit of the North Pole would say they had seen plenty of that before.

Early in 1878 the late Mr. Helman of Croutes, Guernsey, sent me some cuttings without name, which he did not know, and could not find out, so I named it after that place, *Saint Croutes*. It turned out to be identical with the one found by the Rev. F. Freeman at Saddington Rectory, Leicestershire, hence called by him *Saddington*, but found afterwards by importation from France to be *Pollion*. It is still the best in its line, not in its original colour, pink, but white, to which it sported a few years after at Tooting, Surrey.

It must ever be borne in mind that the qualities desirable, and stamping many of these sorts as good and best, are quite different from those of the late sorts and those to win prizes at shows, with the exception of such as *Madame C. Desgrange* and *Léoni Lassali*. They are not fit for the long stick with a flower or two at the top sort of plant, or those monstrosities which look like a kind of illustrated *loo table*, both of which shapes no Chrysanthemum, either early or late, ever grow in naturally.

The most striking point to advance in general estimation these early sorts, and to silence objectors and stir up indifference, was the discovery in the summer of 1879 of *Madame Castex Desgrange* by Mr. Robert Parker, at that time of the Exotic Nursery, Tooting, Surrey. This was found by him in a lady's garden in Wales. On March 15th, 1880, he gave me two little plants of it, and from those two little plants and his stock the bulk of those now in cultivation have come. As is customary, as soon as this variety became known we had the cry common in such cases that it was known before. Old French catalogues were found in which there was the name, but no one had seen the plant. Others said they had it, but I did not find they had the stock. It was in the lists of M. Lemoine and M. Crousse of Nancy, France, of March, 1881, but I expect they had it from England the year before, or raked it up from some place in France, for we had heard nothing of it from them before March, 1881. Lemoine says it was raised by Bou-

charlat. Crousse spells it *Desgranges*. However, it was then, and is now, the very best early Japanese, either in its white and yellow colour, and its primrose sport called *Mrs. Burrell*. It was a curious thing that the very next summer that we heard of the first yellow sport of *Madame C. Desgrange* I found it had sported in six places the same colour. This is one of the curious aspects of sports that after a plant has been grown a number of years from the seed, it sometimes the same year or year after sports in a second or more places, just in the same way that we have three sports of *Mdlle. Lacroix* in three places in 1888; other sorts never sport at all, as in the case of *Nanum*, although it is now old. I have known it since 1877, and it has been grown in all sorts of places and in large quantities for cut flowers, never varying in the least, but being neither better nor worse than the first year grown.

At the end of 1881 we received from M. Lemoine, of Nancy, France, *Lyon*, which is one of the best Pompons of the early kinds we have ever had or have. Its faults are its delicacy in winter and sparseness of cuttings, but in all other respects it is first-class. I have counted 434 florets in a bloom. It is now to a great extent superseded by its red sport, *Alice Butcher*, which is in every respect the same except colour, and reds are much more scarce, also much more liked by the ladies, who are great factors in the cut flower trade; besides, the original colour much resembles *Blushing Bride*. At the end of 1881, too, we received also from M. Lemoine, *Mdlle. Jolivart*. This is still one of the most beautiful and useful Pompons we have. I have not found anything to surpass it in all its good qualities. It has never sported, being white as at first. It was in 1881 that we also received for the first time *La Vierge*, a white October bloomer. I denominate all that bloom up to the end of September early, and those that bloom in October semi-early, which terms are about equal to the French *Précoce* and *Hâtive*.

In 1883 we first discovered the merits of a new sort imported from France by Mr. Ware, of the Hale Farm Nurseries, Tottenham, London. It was called *Late Flora*, but why it was so designated we know not, for it is very early, and the best yellow Pompon in its line. It is a reflexed yellow flower, and blooms for months together, commencing in August. We have dropped the *Late*, and now call it *Flora*, but there are two more *Floras*, late ones.

It was not till 1885 that we found the one we named *Blushing Bride*. It was among a lot of wrongly named old sorts and rubbish imported from France by Mr. Davis, of the Lilford Road, Camberwell, London, and is believed to have been raised by some amateur. This is still the very best in its line, and will bloom twice in one season. In 1886 Mr. T. S. Ware imported from M. Pertuzes, of Toulouse, the raiser, *Leoni Lassali*, which was of an entirely new type among the early sorts, being a large ivory-white flower of a semi-incurved character. It is very beautiful in many respects, not so profuse a bloomer as some, but that is made up for by the beauty and size of the flowers. It blooms in August, and stands alone, being a large-flowered sort, not Japanese.

Grace Attick is the last grand new sort entirely distinct that we have received. I believe it was raised in New York by Mr. John Thorpe, and imported by Mr. Cannell, of Swanley, Kent, in 1887. It is a quite new type of Japanese, a white large flower on a dwarf plant. The very earliest of all Chrysanthemums blooming a month earlier than *Nanum*, and coming out at the very beginning of May, under glass, of course. I believe that this plant will be largely grown, and should we be able to seed it in England, or in some other climate, it will probably be the origin of an entirely new branch of the early blooming sorts. It is very dwarf and bushy, a good grower in summer, but weak and very liable to mould off in propagating in spring, with a disposition to bloom itself to death in summer.

The great uses of these plants are to decorate gardens in the open, even in the north of Britain, where the late kinds would be destroyed by the frost, and to fill the gap in the season between the summer flowers and the November Chrysanthemums. Their dwarf and bushy habit fits them very much for pot plants for decoration and sale as such, while their capacity to supply cut flowers is unbounded. Considering the labour and expense, as well as their durability in a cut state in water, they are perhaps the cheapest and most effective flowers grown. Besides, there is one great point more in their favour, they will grow and flourish in the smoky and dirty air of towns and suburbs, where few plants will flourish, and where no *Rose* will live and bloom.

As to the progress in future the aspects are most promising. Years ago I began to grow seedlings. My first grew very well, and when flowering time came they were still growing into plants of vast size, but no sign of bloom appeared. I then heard, "Oh, they do not bloom the first season." So I saved them till the next year, when their size was magnificent; but the bloom, when it came, was such that we threw them all away at once. Subsequent seedlings were no better. These were all from foreign trade seed. I then began to look around, and on the railway slopes at the back of my ground saw the wild English Chrysanthemum *leucanthemum*, the *Ox-eye* or *Dog Daisy*, in bloom in May; so I thought to double that, but it was no good—all the seedlings came exactly like the parent, in every way so very different in that respect from the seedlings of the other Chrysanthemums, which I then attributed to the foreign seed being from mixed plants. I could get 10 seed from the really early sorts till Mr. John Thorpe sent me a small packet of early seed from New York in 1885, from which I raised over 100 plants, among which there was only one really good early variety, which I named *Piercy's Seedling*. This was my first real success in raising new kinds, for it is really good; but I wished to raise my own seed, so that I should know what I was doing. I tried in vain. I sent plants to Mr. Laxton, the seed grower of Bedford, on hot sandy soil

and to Mr. Elliott of Jersey, with no better results. The seeds, under a strong glass, were seen to be infertile. I then proposed to send the early sorts to the south of France and Algeria, and the Rev. F. Freeman sent some to Ohio, U.S.A. In the meantime I was on the look out for some early single sort. This, through the craze for single flowers, I procured by the kindness of Mr. W. H. Cullingford, who grew a lot of seedlings from seed he had from Mr. Hartland of Cork, Ireland, and named Hartland's Marguerite. It was a great, tall, profuse blooming, nearly single, white Pompon, and I had plenty of seed from it the first season. From this seed the next year I selected two dwarf plants of the best character, and from the seed of these I have now some real beauties. I still have one of these, which I call Seedbearer, which even in last year's bad season perfected good seed.

When I first grew the seed of Hartland's Marguerite it was with immense surprise I saw that instead of the plants being all alike they were nearly all different from the parent, though there was a family likeness in some of them. Last season I again grew the seed of these two selected plants separate, and have as their descendants Goldsmith, a fine early yellow Pompon, which will bloom twice in one season; Clara, good early white Pompon; Miss P. Broughton, late white Pompon; White Lady, lovely early white Pompon; Dod's pretty little yellow dwarf Pompon, and others. Besides these, the year before last I had good seed from Salter's Early Blush, from which I have raised an advance on it I have named Jacintha. We have also from the seed of these two seedlings, among the plants grown at Mr. Ware's nursery last season, a very beautiful dwarf white Pompon named Duchess of Fife; it is about a foot high, and was in bloom August 12th. The flowers resemble Mdle. Marthe. It is entirely different from all others. We had also from this same lot of seedlings grown at Mr. Ware's the most beautiful early yellow Pompon in cultivation. We have named this Golden Shah. The colour is the very finest deep yellow, very bright; the flowers are 2½ inches across, deep, full, and reflexed. The plant grows 2 feet high, with slender but strong habit; the foliage very spare indeed, and each flower has a good long stalk, so that every bloom can come out, which renders it very good for cutting purposes, besides giving the plant a very elegant appearance. It is a very rapid grower. Thus two plants raised from cuttings in March 24th were in full bloom by July 25th, and two more struck on May 24th were in full bloom July 29th. It stands rain wonderfully well for so delicate a flower, and it is certainly the very finest early English seedling up to this time, as well as being the best early Pompon, English or foreign. It is remarkable also as being raised from seed saved at Forest Hill, and only two generations from the poor white Hartland's Marguerite, which was nearly single. All this is not only good as regards Chrysanthemums, but very wonderful as an illustration of vegetable physiology. I regard it as a revelation in itself worth having, apart from the gain of such a plant.

The greatest and earliest friends and helpers in what I may call the modern history of these sorts, which began in England about 1868, are Mr. Shirley Hibberd; Mr. Watson, sen., now of Bowes Park, Wood Green, Middlesex; Mr. N. Davis of Camberwell; Mr. W. H. Head of the Crystal Palace; and the Rev. F. Freeman. I have to thank all these gentlemen and many others for their friendly help, and also the members of the horticultural press, not forgetting Mr. Libby of New York.

We now want a few more enthusiastic amateurs, and any spare money we can get, for these are the things to help on the progress of these early varieties, which appear capable of boundless extension.

[By Mr. T. Turton, Maiden Eridge Gardens, Reading. Read at the Chrysanthemum Conference, St. Stephens' Hall, Westminster, September 11th, 1889.]

HAVING been successful now for several seasons past in obtaining a good display outdoors with the early Chrysanthemum, and complying with a request from Mr. A. Dean, I send a few notes respecting our method of growing them. This, however, is so simple that a very few words will suffice to explain it.

First, as to raising the plants, let me say it is solely to the generous treatment given the cuttings that I attribute our success. But here I must explain that we force a great quantity of Asparagus through the spring in frames on hotbeds. It is there we raise our plants, by dibbling in the cuttings early in February among the Asparagus. The moist atmosphere from the dung keeps the cuttings fresh until they emit roots, which does not take more than a fortnight. They are then placed into small sixty sized pots, and returned to the frame. There they quickly take to the new soil, and are soon growing apace. We stop the plants once only, which is done at this stage, and as soon as they have started they are hardened, and in due time are shifted into forty-eight sized pots. In these they make strong plants, and are placed out in the first favourable weather we have in May.

Respecting the names of the varieties we grow, I should like to class them in three sections.

Section I. comprises those which are in flower with us from the beginning of July. They are Mr. W. Piercy, colour brick-red; Précoceité, yellow; St. Mary, white; Madame Jolivet, blush-white; Nanum, creamy-white; Madeline Davis, yellow; St. Croutes, pink; and White Croutes, white. Anastasio, a light purple, we have had good only once or twice, and as it is not flowering at all this season it will now be discarded.

Section II. includes Madame C. Desgranges and its sport G. Wermig. These two varieties are the most useful of all. They are in flower from the beginning of August until cut down by frost. It has long been my

wish to see varieties introduced into this section of bright colour, and possessing the good qualities of the Desgranges type, when, I think, it would be difficult to imagine anything more beautiful through the months of August and September than a wide border, the front planted with varieties of this section, backed with Dahlias of the Cactus and single flowering varieties.

Section III. contains La Vierge, pure white; Lyon (hybrid Pompon), bright rosy purple; Inimitable (Pompon), amber; Pomponium (Pompon), light orange, Alexander Dufour (Jap.), bright purple; and Roi de Précoces (Jap.), bright crimson, a splendid variety. These flower through October.

I would add, as explanatory of my growing these early blooming Chrysanthemums in such considerable quantities, that having to supply flowers largely during the fishing and grouse-shooting season in the summer and autumn in Scotland, I find none to travel a long journey so well as do the Chrysanthemums. Flowers cut here at midday and despatched per rail at 2 P.M. from Earley, reach their destination in Scotland during the following afternoon, a period of some twenty-six hours, often during warm weather: yet do the Chrysanthemums invariably arrive fresh and beautiful. That capacity to endure long journeys packed I attribute to their being well-matured by outdoor exposure and the hardness of the stems, whilst those of more tender flowers being more sappy wither the sooner. To be able to send flowers fresh and sweet so long a journey is, in these days, a matter for congratulation, and shows how much gardeners owe to the introduction of the early blooming Chrysanthemum.

DEVIZES CHRYSANTHEMUM SHOW.

THIS will take place this year on Tuesday, Nov. 12th; unfortunately, in some respects, on the same day as the great Show of the National Chrysanthemum Society at the Royal Aquarium. Some excellent plants and cut flowers are always seen at Devizes, and the townspeople support the Exhibition by attending in large numbers. The Show forms a part of the programme of the Devizes Benevolent Society, which holds a Flower Show and Bazaar in aid of its funds in combination. The amount realised by the Bazaar and Flower Show is expended by the benevolent district visitors in various ways for the benefit of the deserving poor. Prizes are also offered for Primulas in pots, and some of the best specimens we have ever seen are grown in the neighbourhood. The manager and superintendent of the Show is Mr. Thomas King, Castle Gardens, Devizes.

"SETTING" VERSUS "TAKING THE BUD."

I QUITE agree with Mr. Baker, page 183, that the term "taking the bud" is a misleading one. I remember some years ago having a rather disagreeable demonstration of this fact. After, as I thought, duly explaining the method to one of my assistants, I sent him to take all that were forward enough. Fortunately, however, I visited him soon after, for I found he was really "taking" the buds. Yes, he was carefully nipping out the flower buds, and leaving the wood buds. He was sure I told him to "take the buds," and how could I call leaving them on the plants "taking them?" This may be considered an extreme case, but it sufficiently shows the importance of using positive instead of negative terms. A tyro, on being told to take the buds, would not think of leaving them on the plants unless especial instruction was given him to that effect. Almost all that I have explained the method of "taking the bud" to for the first time, have declared the practice directly contrary to their preconceived notions of it.

The term "setting the bud," as suggested by Mr. Baker, would be far more descriptive of the actual practice, and would be readily understood by the younger members of the craft.—J. H. W.

NOTES AT READING.

TRAVELLERS to or through Reading by the Great Western line have probably observed the broad stretches of flowers on the lefthand side just before the town is entered. They present a bright picture of floral beauty on a cheerful autumn day, and remind the visitor that the pleasant Berkshire town which has been for so many years famed for its biscuit-manufacturing industry can boast another of hardly less magnitude—that of the culture and distribution of garden and farm seeds. Messrs. Suttons' great establishment there is a world-famed one, and the huge blocks of buildings bearing their name are conspicuous even in close proximity to the extensive and lofty manufactories of the biscuit trade. There is little time to take note of them before the station is reached, but those who think well to spend an hour or two in inspecting what Messrs. Sutton have to show them will be well advised. The great seed establishment is easily found, and courteous attention is paid to any visitor interested in horticulture who may call. Gardeners generally will perhaps not find it of special interest to wander over every floor of the huge warehouses, but at the trial and seed-saving grounds, to which they will be directed on inquiry, they will find abundant material for admiration and reflection. The grounds are situated in London Road, Reading. The outdoor portion is devoted to special trials of various crops, the glass—of which there are extensive ranges—to the culture for seed of the choice florists' flowers for which the firm is so much noted. It may be said at once that no department of the enormous seed business reflects higher credit on the firm than this. Begonias, Primulas, Cyclamens, and other flowers are grown in surprising numbers, and the strains—the work of many years' careful selection

and hybridisation—are of the highest merit. The plants are splendidly cultivated. Nowhere in the kingdom can the flowers named and numerous others be found in finer condition. One or two present features of the nursery are referred to.

BEGONIAS.

What Begonias were ten or fifteen years ago most gardeners know well, but there have been great changes. The Begonia of that date was a loose straggling plant, not too well furnished with bloom, and with a limited range of colour. What it is now a visit to any of the shows where one of the great growers is exhibiting strongly will explain far more eloquently than words. Messrs. Sutton have had a large share in the work of improvement, and their strain embraces all the points required in a first class Begonia—namely, dwarf, compact habit, free blooming, and large flowers of clear, decided, and well varied colours. The Begonia houses at Reading are a most striking sight just now. The plants, it should be borne in mind, are cultivated for seed, and they are grown in large blocks of distinct colours. For instance, there are scarlet, white, rose, crimson, blush, and yellow, all exhibiting the same qualities of large flowers, full of colour, free blooming, and good habit. Those who have purchased Begonia seed by the packet, and received a quantity which a breath would dissipate, will be able to realise the demand for seed when it is said that many ounces are saved and distributed yearly. The plants now flowering are not much more than six months old, the seed having been sown in February. It is curious to note how the Pearcei blood shows itself amongst them. That useful old Begonia was the parent of the beautiful varieties seen to-day. In some flowers the rich colouring is so intensely concentrated that it has suffused the stigma, as though unable to find development in the petals. Here is a singular fact. A cross was effected between *B. semperflorens gigantea carminea rosea* and *B. metallica*, and the result of the union of these two fibrous-rooted varieties has been the production in one year of a tuberous-rooted form.

CYCLAMENS AND PRIMULAS.

It would not be easy to derive more pleasure from a batch of plants out of bloom than is gained by inspecting Messrs. Sutton's Cyclamens, which are now in free growth. There are thousands of plants growing in such vigorous health that one could imagine this one of the easiest plants to cultivate; but Cyclamens have their peculiarities, which bring many persons to grief. Undoubtedly one common cause of failure, or of only partial success, is the necessity for growing the plants in a mixed house. They have likes and dislikes of their own, especially regarding moisture, which cannot be so carefully studied when other plants are grown in association with them as when they are cultivated alone, and unfortunately the difficulty is usually unavoidable. There are three well marked periods in the development of these beautiful plants. First there is that of root formation, secondly that of leaf growth, thirdly that of blooming. As the flowering period lasts several months no one will question the importance of building up a thoroughly vigorous and healthy plant to support it. Free healthy root action, followed by a steady unchecked development of sturdy leaf growth, are the forerunners of abundant blooming. Messrs. Sutton secure them all by a course of treatment based on long and careful study of the requirements and peculiarities of the plants. At the present time they are in the perfection of health and strength, well clothed with stout foliage, having a spread in one batch of nearly a foot, and with abundance of bloom buds clustering at the base. They are saturated with moisture, and revel in it at this period of the year, and the atmosphere of the house is of that genial, pleasant humidity so agreeable both to men and plants. The seed was sown in November. Primulas are making healthy growth in pits. Nothing could look more thriving and comfortable than they.

GESNERA ZEBRINA DISCOLOR.

This useful plant well deserves a note. It is valuable from its blooming in late autumn. Plants at Reading are just coming into flower, but will not be at their best for some time yet. The attractiveness of the plant consists in its large, handsome, velvety, heart-shaped leaves as much as in the flowers, pleasing though the latter are. They are borne well above the foliage, and are vermilion or bright scarlet in colour, the throat dotted with white. This *Gesnera* is of easy culture. It may be readily raised from seed. Messrs. Sutton sow in February, and the plants come into bloom the following year. They are growing in 6-inch pots, and such handsome specimens are of much value for decoration in the dull season.

CLIANTHUS DAMPIERI.

I refer to this plant to note a curious instance of its capricious character. Some seeds were sown in heat in February, and the plants put out on a sunny border in May. Though the plant had repeatedly caused disappointment before, it now grew vigorously and rapidly, one developing into a grand specimen a yard or more through, well furnished with flower spikes. With a large number of its rich red flowers, conspicuously centred with black, open at once, it was an undeniably fine and striking object. But more curious still, a little seed was sown out of doors on the same border in May; the plants grew freely, and are now blooming profusely, although they have not, of course, attained anything like the dimensions of the fine specimen referred to. Many have failed to grow and flower this plant well after devoting the utmost care to it. Here is an example of what it will do when practically left

to itself. It is probable that the extremely hot and dry weather in early summer suited it.

It is not possible in a few hasty notes taken when other work was waiting to be done to exhaust the features of interest in Messrs. Sutton's admirably managed seed grounds; but it may be added that another extensive trial of Tomatoes is being conducted, and the quarter devoted to them is a marvellous sight. The plants are grown about 9 inches apart, and trained to strong stakes $3\frac{1}{2}$ feet high. The fruit commenced colouring on August 7th, and the plants are now loaded with ripe and ripening fruit. Among a large number of varieties Earliest of All and Perfection are conspicuously excellent. There is also a trial of Melons, and if a better variety than Hero of Lockinge is found there will be something to be proud of. About an acre of Asters are being grown in separate blocks of some hundred plants each, producing a very fine and diversified effect. They range from 6 inches to $1\frac{1}{2}$ foot in height. The seed was sown out of doors at the end of April. Phloxes and many other attractive flowers are also largely grown, indeed both indoors and out this seed-saving establishment is full of interest and beauty.—W. P. W.

EVENTS OF THE WEEK.—The Manchester Royal Botanical and Horticultural Society will hold an Exhibition of fruit and flowers on Friday and Saturday, September 20th and 21st. The Royal Horticultural Society's Vegetable Conference will be held in the gardens at Chiswick on Tuesday, Wednesday, and Thursday, September 24th, 25th, and 26th, the Fruit and Floral Committees meeting on the first day at 11 A.M. A gardeners' dinner will be held at the Cannon Street Hotel on the evening of September 24th, at 6 P.M., Mr. H. J. Veitch in the chair. Tickets can be had from Mr. A. F. Barron.

— **THE WEATHER.**—A period of clear bright weather has rendered the past week most agreeable, but it has led to what many expected—an early frost, which, on the morning of Tuesday last blackened the Dahlias in numerous gardens. Mr. E. Mawley recorded 6° on the grass at Berkhamstead, and this would almost seem to corroborate one statement that 9° had been registered at Slough, though that appeared incredibly severe. Mr. John Doughty, The Gardens, Angley Park, Cranbrook, Kent, writes:—"We had a very severe frost on September 17th; ice thicker than a penny was found in the greenhouse gutter. Chrysanthemum leaves were frozen to each other; they were syringed, and thin pieces of paper laid over the buds until thawed, but I fear it has done them great damage." Mr. T. Laxton also writes from Bedford, "A sharp frost here last night (September 16th), the first of the season. Cucumbers much cut, Marrows slightly; Dahlias, Runner Beans, and Tomatoes do not appear to have suffered." In the neighbourhood of London Vegetable Marrows, Beans, Tomatoes, and Dahlias have been injured or destroyed in many gardens.

— **NATIONAL VEGETABLE CONFERENCE AND EXHIBITION, CHISWICK, SEPTEMBER 24TH, 25TH, AND 26TH.**—This promises to be a specially interesting meeting, entries of exhibits having been received from all parts of the country. Scotland and Wales will be well represented. We also learn that M. Vilmorin of Paris will be present with a large number of exhibits, and consignments from America are also expected. We may remind our readers that the entries close on the 21st, and that those who have not given notice should do so at once.

— **WE** are desired to state that the **COLLECTION OF ORCHIDS** formed by the late Hon. and Rev. J. T. Boscawen, at Lamorran, Cornwall, will be sold by auction on the premises on October 3rd.

— **RATS IN GARDENS.**—"L. K." would be very glad to know if there is any way of getting rid of rats that infest a garden, and are to be seen in broad daylight eating the Peas, &c. Poison has been tried, phosphoric paste, and other things. Though the poison disappears, the rats are just as numerous. They will not go into any traps.

— **THE Kew Bulletin** for September contains articles on "The Flowers of *Calligonum polygonoides* as an Article of Food in N.W. India." Coca, Buaze fibre (*Securidaca longipedunculata*), vegetable productions from Central China, Vine cultivation in the Gironde, and *Phylloloxera* in South Africa are also treated upon in several letters and notes.

— **EARLY ASCOT PEACH.**—A correspondent, "R. R." asks if any of our readers who have grown this Peach will oblige by stating their experience of its cropping qualities and the flavour of the fruit.

— WE are informed that MESSRS. KELWAY & SON, LANGPORT, provided a display of cut Gladioli, Pyrethrums, Gaillardias, Dahlias, and Globe Quilled Asters at the Paris Exhibition from September 6th to 11th, and the Jury awarded them a premier prize in addition to the awards granted earlier in the season.

— I SAW in a recent issue of the Journal, page 229, an interesting paragraph on Yuccas. We have one plant here of *YUCCA ALOIFOLIA VARIEGATA*, 8 feet high, which is in bloom, though past its best. The spike of flowers is a little over 2 feet high, and colour similar to the one your correspondent describes at Hamilton Palace. It is a noble plant, and splendid spike of flowers. It has been a great source of attraction to the visitors to the park, thousands coming to see it. Do any of your readers know of one of this variety that is in flower in England?—MICHAEL LANDER, *Manager, Horton Park, Bradford, Yorkshire.*

— THE following is the award of the arbitrators appointed in the case of HAWKINS & BENNETT v. WARE, which was fully summarised on page 215:—"We do award and certify that the plaintiffs' and defendant's Chrysanthemums, the subject of this action, are identical. That the plaintiffs are not entitled to any damages for the user of the name, title, or description 'Mrs. Hawkins' as applied to a Chrysanthemum plant, for which the plaintiffs were awarded two first-class certificates of merit in September, 1888, and we award that the plaintiffs pay the whole of the cost of the action up to the date of the Order of Reference, the 22nd day of August, 1889; and we further award that the whole of the costs of the arbitration and award be borne in equal moieties by the said plaintiffs and defendant respectively."

— "GARDEN ALLOTMENTS; THEIR ADVANTAGES AND UTILISATION."—Mr. J. Wright's lecture on the above subject, delivered at Nottingham, and which subsequently appeared in this Journal, is, in response to requests from clergymen, land proprietors, and gardeners, old and young, issued in the form of a neat pamphlet of thirty-two pages. We quote from the preface:—"In order that the greatest number to whom it may be suggestive can obtain a copy, it is circulated at a low price—3d., by post 3½d. Private gentlemen, clergymen, and others who desire copies for distribution will be supplied in parcels of fifty and upwards at the rate of £1 per 100, carriage free. Co-operation is requested with the object of improving cottage garden and small allotment cultivation in various parts of the country." It is published at the office of this Journal.

— **SHOW OF ASTERS AND MARIGOLDS AT KELSO.**—Encouraged by the general success which has attended their former competitions, Messrs. Stuart & Mein, the enterprising firm of nurserymen and seedsmen at Kelso, offered some time ago four prizes each for Marigolds and Asters to be grown from seed supplied directly from them, and accordingly a Show took place within the premises in Wood Market occupied by the firm on Friday last. No fewer than 840 blooms were staged, and the competition represented a very wide area, the following being a few of the counties from which blooms were sent:—Forfarshire and Aberdeenshire in Scotland; Staffordshire, Shropshire, Wiltshire, Buckinghamshire, Warwickshire, and Cornwall in England; and also from a few of the counties of Ireland. In point of quality the Show was exceedingly fine, and in the course of the afternoon it was largely patronised, the arrangements being similar to those at former competitions.—(*Kelso Chronicle.*)

— ONE of the most tasteful and effective RIBBON BORDERS we have seen this season is in Mrs. Treadwell's garden, Leigham Court, Streatham Hill. It is on the lefthand side of the carriage drive leading from the main road to the house, and is about 2 feet in width. The groundwork is a dense dark green carpet of *Herniaria glabra* margined on the side next to the drive by a neatly clipped low hedge of *Euonymus radicans variegata*, upon the other side by *Kleinia repens*. Upon the *Herniaria* at short intervals are elliptical panels of *Alternanthera amoena* and *A. paronychioides aurea* alternately, both being capitally coloured, and between these are plants of *Chamaepeuce diacantha* and *easa-bonae*, with a few taller plants of *Pachyphyton*. It is unpretentious yet very effective and excellent in all respects. The garden generally at Leigham Court is a model of good keeping, and shows the skill and care of the gardener, Mr. E. Butts, in every department.

— **FRUIT GROWING IN ENGLAND.**—During the past few months the Fruiterers' Company have received several valuable suggestions as to the encouragement of fruit culture in England from the Lord Mayor, Mr. Henry Chaplin, M.P., the President of the Board of Agriculture, and many other gentlemen, have passed the following resolution:—Resolved, that the Fruiterers' Company feel strongly the great importance of the question of fruit farming in England, and view with much concern the want of attention paid to the production of Apples, Pears, Plums, and other hardy fruits of fine quality, and deplore the frequently neglected state of many of the existing orchards. The Committee therefore desire to encourage the development of the profitable culture of fruits of high quality in England for the advantage of the grower and consumer, and for the better utilisation of agricultural land. With this object the Company propose to establish a fund of not less than £5000 (towards which they are willing to contribute £500), from the income whereof they intend annually to offer prizes for the best managed fruit farms, plantations, or orchards. The Lord Mayor has undertaken to receive at the Mansion House subscriptions to the fund, and they can also be sent to the Clerk of the Company, Mr. O. C. T. Eagleton, 40, Chancery Lane, London.

— **NOTTS HORTICULTURAL AND BOTANICAL SOCIETY.**—The monthly meeting of the Notts Horticultural and Botanical Society was held on Wednesday evening, September 11th, at the Arboretum Rooms and was well attended. There was a good show of plants, cut flowers, fruits, and Ferns, a speciality being the exhibition of *Gladiolus* blooms, of which several new specimens were shown. Plants, flowers, and vegetables were sent for exhibition by Mr. J. Robinson (gardener, Mr. J. Plumb), Mr. W. H. Farmer (gardener, W. Attenborough), Mr. C. J. Cox (gardener, J. Meadows), Mr. J. Fearfield (gardener, J. Underwood), Mr. T. Hallam (gardener, W. Newton), Messrs. J. R. Pearson and Sons, Chilwell; Mr. E. Massey (gardener, W. Bateman), Mr. T. B. Hallam, Corporation Road; Messrs. James Booth, J. Baker (Basford), and J. W. Turner. The exhibits were of a choice description, and amongst them were splendid specimens of hothouse Grapes and Tomatoes. The feature of the evening, however, was Mr. A. H. Pearson's paper on "A Visit to the Bulb Farms of Holland." Mr. Pearson, who is a member of the well-known firm of Messrs. J. R. Pearson and Sons of Chilwell, has recently paid a visit to the Netherlands—as he says the country is properly called—and has given his friends, who are interested in horticulture, the benefit of his impressions on bulb growing in Holland. We have been obliged with the paper referred to, and it will be published in an early issue of this Journal.

DOGMERSFIELD PARK, WINCHFIELD.

THE owner of the beautiful gardens and grounds of Dogmersfield Park, Sir Henry St. John Mildmay, Bart., is generous enough to throw them open to the public two days in each year, a privilege which is much appreciated in the neighbourhood. On the 2nd of this month, I, in company with many others, wended my way thither in response to one of these annual invitations, and it occurred to me that a few notes taken on the spot might prove interesting to your numerous readers. We entered by what are called the "golden gates." These are massive ornamental iron gates, with the shield and arms of the family in burnished brass, and they open on the

FLOWER GARDEN.

Vases containing choice specimens of Ivy-leaf *Pelargoniums*, *Fuchsias*, &c., stand on each side of the gates and at approximate angles all over the gardens. Inside the gates, on each side of the walk a plateau of Ivy with its rich green leaves forms a good background to what is one of the chief attractions to all visitors. The carpet bedding is a feature here. The beds were arranged in pairs crosswise, say a pair of oblong beds filled in with Zonal *Pelargoniums*—the crimson would be opposite the scarlet, and *vice versa*, thus avoiding formality and giving a pleasing distribution of colour. A large number of oblong and round beds filled in with every conceivable mathematical design worked out in flowers or foliage plants showed exquisite care and skill in the exactness of outline, arrangement and blending of colours, and extreme neatness combined with endless variety. Mr. G. Trinder is the head gardener, and what struck me year by year is the way in which he uses the simplest plants he has at hand to produce the most marked results. All the circular beds were raised a foot from the ground, with bevelled edges of *Herniaria glabra*, and this avoided the look of flatness that we often see in carpet bedding, and which is an objection.

Here are a few specimens of the plants used in some of them. Two round beds. No. 1.—Central plant a variegated Yew, surrounded with *Abutilon vexillarium variegatum*; panels, *Oxalis tropaeolioides*; marginal lines, *Leucophytum Browni* and variegated Thyme; groundwork, *Herniaria glabra*. Round beds, No. 2.—Centre, *Alternanthera versicolor*; panels, *Mesembryanthemum cordifolium variegatum*; marginal lines, *Leucophytum Browni*; groundwork, *Sedum acre elegans*. Round beds,

No. 3.—Centre, *Alternanthera paronychioides* major; panels, *Alternanthera amena*; marginal lines, *Spergula pilifera* aurea; groundwork, *Antennaria tomentosa*. Round beds, No. 4.—Centre plant of *Grevillea robusta*, surrounded with *Iresine Herbsti*, *Iresine Lindenii*, and *Iresine Wallsi* in circles; panels, *Iresine Lindenii* and *Alternanthera paronychioides* major; marginal lines, variegated Thyme; groundwork, *Sedum aere elegans*. Round beds, No. 5.—Centre, *Alternanthera versicolor* and *amena*; panels, *Alternanthera magnifica*; marginal lines, *Leucophytum Brownii*; groundwork, green *Spergula pilifera*.

Several oblong beds showed also pretty designs, and those filled with Zonal Pelargoniums Mrs. John Gibbons and Henry Jacoby were very brilliant in colour, to which their borders of *Ageratum Perle Bleu* gave a pretty relief. I observed that the several designs were much studied and commented on by the visitors, even the children evincing great interest. In these days of "schools of art" gardeners must look well to their laurels in this department. A diamond inside a square for the centre of a circular bed was much remarked. Four large statuary vases of the *Fuchsia Charming* presented a mass of bright blossom that

the graceful branches of a Tree Fern or Palm distributed here and there among the flowers.

The fernery comes next, and its walls are covered with a variety of Ferns on a groundwork of *Selaginella Kraussiana*, and it contains some very fine pots of various Maidenhair Ferns, such as *Adiantum formosum*, *Pacotti*, and *gracillimum*. Outside I noticed some large beds of Marie Louise Violets, from which the gardener told me he had been cutting the last six or seven weeks, and still there were plenty.

The border walk is made up on each side with *Heliotrope Duchess of Edinburgh*, Zonal Pelargoniums Titian and Master Christine scalloped out with the Ivy-leaf Madame Crousse and *Sedum spectabile*. In the walk leading from the gardener's house to the kitchen gardens are some pretty lozenge beds alternated in variety with gold and silver *Retinospora*, and these show up well from a groundwork of *Herniaria glabra* used instead of grass. Here we see again those wonderfully cut walls of Holy and Yew that excite the admiration of all visitors to Dogmersfield.

In other borders may be seen in profusion all the ordinary border

FIG. 33.—DOGMERSFIELD—THE FLOWER GARDEN.

justified its name, and these were surrounded with the Ivy-leaf Pelargonium Fürstin von Hohenzollern.

This garden is flanked on the left by a very high wall covered with Tea Roses and some fine old Magnolias now in bloom, under which runs a border of *Sedum spectabile*. On the right is a grassy slope flanked by a solid wall of closely cut Yew, and on each side are pleasant alcoves wherein to sit and contemplate the beauty of the scene.

THE CONSERVATORY.

No space is lost at Dogmersfield. A border of yellow Marguerites, *Heliotrope*, and *Begonia Princess Beatriee* runs the whole length of the conservatory, which we now enter. Here are fine specimens of such plants as *Lilium auratum*, Orchids, *Cypripedium insigne*, *Begonias* in all colours, *Chrysanthemums* Madame Desgrange and G. Wernig, &c., *Coleuses* in different varieties, and Ivy-leaf Pelargoniums, including *Souvenir de Charles Turner*, *Galilee*, *Alice Crousse* &c., with remarkably fine blossoms. These were also used in the hanging baskets, their lovely drooping branches filling the upper space. On the walls were *Lapagerias* red and white, covered with their pretty waxen bell-shaped flowers; also a trained *Heliotrope*, which blooms all the year round. *Fuchsias* of different sorts add to the brightness, which is relieved by

and shrubby plants, Dahlias, single, double, and Cactus; Zinnias of all shades; Marguerites, white and yellow Everlastings; edgings of the blue Lobelia, &c. Nor must we omit to mention the old-fashioned garden which contains old-fashioned flowers and sweet-swalling herbs. This is a favourite spot, and at the end of it is an ancient Apple tree with a cosy seat. Clematis arches covered with masses of rich purple blossom span the different walks in the kitchen garden and leading to it, and these are every year a great source of admiration.

The small plant house is filled with a very healthy stock of various plants for winter flowering, among them Poinsettias, Euphorbias, Eucharises, Gardenias, Cypripediums, and various other Orchids.

FRUIT

After lingering a long time in this pleasant region of flowers I passed on to one equally tempting—that of fruit. Grapes in the early vineries had all been cut, but of late Grapes there was a fine show of superb bunches, which, alternating in black and white and surrounded by healthy looking foliage, formed a most refreshing and pleasing picture. Alicante, Gros Colman, Muscat of Alexandria appeared to be the sorts principally grown.

In the Fig house a large second crop of fine Figs are now ripening,

and here I was shown a Maréchal Niel Rose, budded last summer, which has thrown out a number of large shoots from 12 to 16 feet long, and is still growing, apparently quite free from blight, and very healthy looking.

The Peach house was empty, the first crop having come to an end, but in the open some heavy crops of fine luscious fruit were seen on the walls. Such sorts as Noblesse, Barrington, Grosse Mignonne, and Princess of Wales did honour to their names, both as to quantity and quality.

Pears are a special feature at Dogmersfield, and some very fine fruit is grown, Williams' Bon Chrétien, Jargonelle, Madame Treve, and others. Those for exhibition are chosen from Pitmaston Duchess, Beurré Diel, Beurré Clairgeau, Beurré Bachelier, and King Edward.

Strawberries are grown in quantities averaging over a thousand plants, and there is still some fruit in the open. Vicomtesse Hericart de Thury, Keens' Seedling, President, and Sir Joseph Paxton are the favourite sorts, and they answer well here.

Tomatoes are showing plenty of fruit indoors and out.

The fruit room is beginning to receive its autumn stores, a quantity of fine Pears and Peaches being already on its shelves.

The kitchen garden shows an abundance of vegetables of all sorts, with salads and culinary fruits.

Sir Henry St. John Mildmay is fond of his garden, and takes a great interest in it, and he is fortunate in having a gardener who knows how to make the most of the resources entrusted to him, Mr. Trinder having almost if not quite solved the problem, "How to have plenty of flowers, fruit, and vegetables from January to December."—H. A.

ROYAL HORTICULTURAL SOCIETY.

SEPTEMBER 17TH.

THIS meeting was not a largely attended one, either by exhibitors or visitors, but there were sufficient Dahlias and miscellaneous exhibits with fruit to occupy the Committees for an hour or two. The weather was extremely fine, but the sharp frost in the morning had injured some outdoor plants and flowers.

FRUIT COMMITTEE.—Present: R. D. Blackmore, Esq., in the chair, and Messrs. Philip Crowley, J. Cheal, W. Bates, J. Willard, G. Bunyard, A. J. Pearson, T. J. Saltmarsh, G. Wythes, J. Hudson, H. Balderson, F. Q. Lane, Harrison Weir, G. Cummins, C. Haycock, J. Wright, and Dr. Hogg. Mr. Ross, Welford, sent a seedling Pear from Calebasse Grosse, a handsome-looking fruit, resembling Doyenné Boussoch, and, like it, decaying at the core. Quality not superior (passed). Mr. Brutton, Yeovil, sent fruits of Brutton's Perfection Melon, smooth, yellow, slightly netted, medium-sized fruits of moderate quality (passed). Mr. F. Taylor, Swindon Gardens, Cheltenham, sent a scarlet-flesh Melon named Swindon Hall Perfection, deep fleshed, rich in quality, but somewhat destitute in aroma. A good Melon, and only lost a certificate by two votes. Mr. G. Hawkins, Ewenny Priory, Bridgend, sent a ribbed Melon of fairly good quality, but appeared as if it had been cut too long for being presented in the best condition (passed).

Fruits of the so-called Melon Pear, *Solanum guatemalense*, bearing a general resemblance to those of the Egg Plant, were sent from Chiswick. They were grown in the same way as Tomatoes, and in quality reminded of a bad Melon with a suspicion of Cucumber flavour, a bitter-sweet mixture of essences that few if any palates could enjoy. It was generally considered useless for dessert purposes.

W. Roupell, Esq., Roupell Park, S.W., exhibited an interesting collection of eighteen varieties of Grapes grown in the same house, several of them (Frontignans) not often seen nowadays, though, if naturally small, very delicious. The following comprised the collection—Muscat Hungary, Canon Hall Muscat, very good; Mill Hill Hamburg, good; Purple Constantia, superior to Black Frontignan; Grizzly Frontignan, very good; Chasselas Musqué of Herr Horvath, inferior as compared with the Chasselas Musqué of Rivers; Dr. Hogg, excellent; Old Black Frontignan, Ascot Frontignan, Diamant Traube (certificated); Primavis Frontignan, Trovère Muscat, Trebbiano, Muscat Hamburg, Foster's Seedling, July Frontignan, and American Strawberry. A silver medal was unanimously recommended for this collection, and a first-class certificate was awarded for *Diamant Traube*. This is a nearly round white Grape of refreshing quality, with good sized berries but not large bunches. It is not new, but Mr. Barron says, in his "Vines and Vine Culture," was received from M. Leroy of Angers many years ago, but lost sight of for a time. It ripened in an unheated house at Chiswick. The Committee were of opinion that the variety was capable of development by good culture, and might form a valuable companion to the Black Hamburg. In berry it is superior to either Foster's Seedling or Buckland Sweetwater—to the former in size, and the latter in quality—and it will be suitable for growing with little artificial heat.

Messrs. William Paul & Son, Waltham Cross, exhibited an extensive collection of Apples, nearly all the varieties, upwards of seventy, being represented in admirable condition. Messrs. Paul also staged a number of good Pears (silver medal). Messrs. John Laing & Sons exhibited nearly forty very fine dishes of Apples (bronze medal). Mr. Charles Edwards, Newton House, Brickley, exhibited two dishes of Apples, Ecklinville Seedling and Lord Suffield, for which a cultural commendation was awarded.

FLORAL COMMITTEE.—Present: W. Marshall, Esq., in the chair; Messrs. R. Dean, W. Holmes, B. Wynne, Lewis Castle, T. W. Girdlestone,

J. Walker, W. C. Leach, C. Noble, E. Mawley, W. Goldring, George Paul, Shirley Hibberd, J. Douglas, and Dr. Masters.

Mr. C. Ross, Pendell Court Gardens, Bletchingley, exhibited five flower heads of *Aphelandra cristata* with long tubular scarlet florets—large elliptical leaves. It is a fine old plant rarely seen in good condition, and a cultural commendation was awarded. The specimens were gathered from a plant 4 feet high, planted out in a stove and bearing thirty large heads. From the same exhibitor came flowering shoots of *Hibiscus pedunculatus*, a cool greenhouse shrubby plant with soft pale green leaves and large deep pink flowers (vote of thanks).

Messrs. J. Veitch & Sons, Chelsea, had a large collection of greenhouse *Rhododendrons* in many colours and choice varieties, a group of *Hydrangea paniculata grandiflora*, *Berberis vulgaris* loaded with its coral red fruits, *Eucalyptus coccifera* shoots, *Ceanothus azureus albidus*, *Gloire de Versailles*, *grandiflorum* (blue), and the pink *Marie Simon*. Specimens of *Daphniphyllum glaucescens* were also shown.

Messrs. Dobbie & Co., Rothesay, exhibited excellent blooms of double yellow, striped and crimson, and single Marigolds, the strain being commended. Mr. R. Dean, Ealing, had blooms of African and French Marigolds, an award of merit being granted for a double white *Dianthus Heddewigi* named Snowflake. Mr. G. Stevens, Putney, sent blooms of Japanese *Chrysanthemum* Sam Henshaw, purplish upper surface to the florets, silvery reverse; and Annie Stevens, with narrow twisted florets, white, sulphur centre, a good early variety (award of merit). Messrs. J. Laing & Co., Forest Hill, had a group of early flowering *Chrysanthemums* (vote of thanks).

Messrs. Wm. Paul & Son, Waltham Cross, contributed six boxes of Roses, remarkably fresh and grand for the time of year (bronze medal). Messrs. Dickson & Co., Edinburgh, sent two border Carnations named Maggie Lauder, soft pink; and W. M. Welsh, dark scarlet.

Dahlias afforded a brilliant display, and it is probable that they are the last that will be exhibited this season, as some were evidently damaged by the frost on the morning of the day they were cut. Messrs. Paul & Son, Cheshunt, had an extensive and beautiful display (silver medal). Messrs. Laing & Son, Forest Hill; Messrs. Rawlings & Sons, Romford; and Mr. J. T. West, Brentwood, also exhibited well, bronze medals being awarded to all. Mr. C. Turner, Slough, showed several stands of good blooms, and T. W. Girdlestone, Esq., Sunningdale, Berks, had a stand of graceful single Dahlias, mostly varieties he has raised himself. An award of merit was granted for Hester Dorothea, deep maroon, very rich colour, and neat flower.

ORCHID COMMITTEE.—Present: Dr. M. T. Masters in the chair, and Messrs. J. Douglas, C. Pilcher, J. O'Brien, and J. Dominy. There were few exhibits before this Committee, but botanical certificates were awarded for *Disperis Fannina* from A. H. Smee, Esq., Wallington, a peculiar little plant with white hooded flowers in a spike like a small Monkshood. From the same garden came *Masdevallia vespertilio*, with small flowers, buff coloured, with crimson dots, and a similar award was granted for it.

CERTIFICATED PLANTS.

First class certificates were awarded for—

Cattleya Miss Harris (Miss Harris, The Grange, Lamberhurst).—A cross between C. Schilleriana and C. Mossiae, partaking largely of the floral form of the first named species, with a rich crimson lip, and lighter crimson sepals and petals, the colour apparently chiefly derived from C. Mossiae.

Miltonia vexillaria Leopoldi (Baron Schröder).—Flowers of moderate size, pale rose, with a central triangular blotch of deep maroon.

Watsonia iridifolia (J. O'Brien).—Flowers of good size and shape, pure white, ten in a spike, the leaves 2 feet long and more, narrow and Iris-like, said to be the only pure white Irid known.

AWARDS OF MERIT.

Coleus Cleopatra (Hewitt & Co., Solihull).—Leaves of great size, green centre, crimson towards the margin, and yellow or green crenated edge.

Dahlia Conquest (G. S. P. Harris, Orpington).—A peculiar pale purplish mauve, the bloom deep, well proportioned, and even.

Dahlia Marmion (C. Turner).—A fine bloom with yellowish ground colour, striped with crimson.

Dahlia Centenary (Mr. J. T. West).—A Cactus variety, very large flower, of a brilliant crimson scarlet colour, well formed and effective.

Dahlia Gulielma (J. Cheal & Son).—A single variety, with white florets bordered with orange, very distinct.

Dianthus Heddewigi Snowflake (Dean), *Chrysanthemum Annie Stevens* (Stevens), and *Dahlia Hester Dorothea* (Girdlestone), are described in the preceding notes.

STRAWBERRY GROWING.

MR. EASTY's article under the above heading was interesting, as his writings always are, and his expressed opinions will tend to strengthen reports previously given on the merits of Laxton's Noble Strawberry. I have not yet had the privilege of proving its qualities myself, but hope to do so next season. One good variety has not been mentioned by Mr. Easty which deserves notice, and that is Loxford Hall Seedling. This variety has long since been recognised as being above average merit, and those who intend extending their plantations in variety should not fail to give it a

trial. It is of moderate growth, consequently does not require so much space as most sorts, an advantage with those having gardens of moderate dimensions. I obtained my stock from Mr. J. Gibson, Draycot Gardens, Chippenham, who is, by the way, an excellent private grower of Strawberries. With him all varieties, with the exception of the latter, are planted a yard apart between the rows, and 18 inches only from plant to plant. This method is found more economical than the one more generally adopted with private growers—2 feet each way, as more space is allowed for walking between for gathering and attending them; 18 inches provides ample room between the rows, and 15 inches proves sufficient space for dividing the plants of the Loxford Hall variety.

Mr. Easty remarks that his crops were the heaviest he ever had, and attributes the success chiefly to the use of artificial manures. In every instance in which I have directed inquiry as to the Strawberry crops I have learned that they have been the heaviest ever remembered—some attributing the cause to the treatment bestowed, others believing that climatic conditions accounted more chiefly for the heavy crops produced. One individual laid much stress on a close cropping of the leaves at midwinter, in providing him with an abundant supply from a bed which had hitherto proved unprofitable.

Mr. Iggulden has recently enlarged upon a system of growing them as annuals, and I have had proof of their adaptability for such a method in the Marston Gardens, but in the gardens in which I have hitherto had charge the crop have never proved a full one until the second year.

Like Mr. Easty I have good faith in the use of fish manures, but I believe constant moisture is necessary in bringing out its fertilising properties for the use of plant growth. If applied very early in the spring, and followed up with an early mulching, they would prove sustaining; but if used late, and when dry weather prevails, they do not then prove of much assistance to the plants until late summer or autumn rains carried it down to within reach of the roots. Of course, when artificial watering can be resorted to the above remarks do not hold good, but in many gardens unfortunately water is not forthcoming for deluging extensive Strawberry beds. Dr. Hogg and Cockscomb are two excellent varieties, but the latter is not very frequently grown. I believe these two are among the sweetest kinds for dessert procurable. Excepting Noble Sir Joseph Paxton is the most useful and popular Strawberry grown, and were I restricted to one sort only it would certainly be this one.—W. S.

HORTICULTURAL SHOWS.

ANCIENT SOCIETY OF YORK FLORISTS.

THIS Society closed its series of Shows for the summer months on the 11th inst. with an excellent floral display, Dahlias being shown in capital form, Mr. W. Boston, Carthorpe, Bedale, taking chief honours in the Show and Fancy classes, his blooms being superbly finished in form and colour. Besides his competing trays he staged seventy-two blooms, noticeable amongst which was a really good new yellow variety named Miss Hannah Boston; Messrs. J. W. Hutchinson, G. Kirken, and T. Smith being principal prizewinners in other classes of Dahlias. Asters and Marigolds were numerous shown, and very meritorious. Gladiolus were almost a failure, doubtless owing to the fine season having hastened them, so that they are now past their best. The annuals shown were in high perfection, each variety being made up into what may be termed hand bouquets. Of hand bouquets there was a smart competition in the two classes—viz., cultivated and wild flowers, which possessed great merit, and were much admired. Classes were introduced for early flowering Chrysanthemums, but these were not well represented.

The series of five shows held this summer have been much in advance generally of any previous year, and being free to the public have been much appreciated. The Society, it may be said, has extended its area of usefulness much during late years. Much interest surrounds it, doubtless through its origin being so antiquated, dating as it does from the year 1768. The operations of the present year close with the Chrysanthemum Show to be held on the 20th, 21st, and 22nd of November, which now ranks as one of the best in the country.

A plant bearing a fine flower spike of *Aerides Rohaniana* was exhibited by Mr. T. M. Weddall, J.P., for which a certificate of merit was granted.

ROYAL CALEDONIAN.

THIS was held on the 11th and 12th inst., in the Edinburgh Waverley Market, and proved to be one of the largest autumn exhibitions ever held by this Society. Fruit is, as a rule, the predominating feature, and, though it cannot be said to have been an exception to the rule this year, yet the quality of the Grapes, which is generally so fine at this Show, was somewhat below the average. The Newcastle Exhibition, held on the same days, had doubtless something to do with this. Apples, on the other hand, were exceptionally fine, the border counties contributing fine fruit; and, of course, Plums were represented in great numbers, 1000 dishes being staged for Congress purposes alone. Vegetables have never been finer, Leeks, Celery, Onions, Tomatoes, &c., being present in large numbers and of grand quality; but flowers were pretty

well shown, and the plant classes were generally better filled than usual.

In the classes devoted to trade growers the chief exhibits were the tables of plants, 40 feet by 10 feet, arranged for effect. Two firms staged, Messrs. R. B. Laird & Sons being first, and Messrs. Ireland and Thomson second, the competition being rather close. The first-mentioned also led with Palms, table plants, and for twelve plants Chrysanthemums, while the latter were first for a collection of Conifers and hardy shrubs very effectively arranged. Messrs. Dickson & Sons were second for a very good collection. In the cut flower section Messrs. Cocker & Sons, Aberdeen, were first for thirty-six Roses, also for eighteen, and Messrs. D. & W. Croll, Dundee, first for twelve Roses. Most noteworthy were Mrs. J. Laing, Maid of the Mist, A. K. Williams, and Francisca Kruger. Mr. Campbell, Gourrock, had the best thirty Gladiolus. Mr. Forbes, Hawick, had the best Hollyhocks; Messrs. R. B. Laird & Sons the best single Dahlias and cut Chrysanthemums, Messrs. Cocker the finest Show Dahlias, and Mr. Campbell, Auchinraith, the best Fancy Dahlias.

In the gardeners' section the chief prizes were offered for a table of plants 20 feet by 5 feet arranged for effect, there being four competitors. The Judges awarded first place to Mr. Fraser, gardener to J. White, Esq., Ardarroch; second to Mr. Grossart, gardener to J. Buchanan, Esq.; and third to Mr. McIntyre, gardener to Mrs. Pease, Woodside, Darlington. The general opinion was, however, that the first ought to have had the third place, the Judges having been most evidently biased by the Orchids employed, though it was less effectively arranged, the second group being the most artistic of the three, while that of Mr. McIntyre was very bright with Crotons of grand colour. Mr. John Patterson, Millbank, had first for six stove or greenhouse, two Ericas, a fine Eucharis, and *Lapageria alba* being his chief plants. Orchids were good for the season. Mr. Curror, Eskbank, was first for four species, *Cattleya Dowiana* and *Miltonia spectabilis* being the more noteworthy plants. Mr. Fraser had the best two Orchids, and Mr. Curror with a plant of *Cattleya Gaskelliana* took first prize for one Orchid. Foliage plants were very numerous, but no prize ticket could be found on the first exhibit, the second going to Mr. Grossart. Mr. Napier with fine plants had first for *Adiantums*, Mr. Grossart for six exotic species, and Mr. Patterson for three *Gleichenias*. Mr. Grossart had the best *Dracaenas*, tall, strong, well coloured plants, while the best Crotons were furnished by Mr. Brotherston, gardener to the Earl of Haddington, Tynninghame. Mr. Patterson had the finest Cape Heaths, not large, but healthy well-bloomed plants. Mr. J. Pearson, Beechwood Gardens, staged six fine specimens of Chrysanthemums for first prize, while of Fuchsias, Pelargoniums, and Begonias there was a very satisfactory display.

In the fruit section there were six exhibitors with twelve dishes of fruit, of whom Mr. McKinnon, Melville Castle Gardens, Lasswade, was successful in obtaining first place. Of Grapes there were magnificent Alicante and Gros Maroc, good Black Hamburg, beautiful Golden Hamburg, and fair Muscat of Alexandria. Peaches were good, Pitmaston Duchess Pears fine, the other dishes being Lord Strathmore Melons, Marseilles Fig, Pitmaston Orange Nectarine, Queen Apples, Jefferson Plum, and Moorpark Apricots. Mr. McIndoe, Guisborough Hall Gardens, second with good Gros Maroc, Gros Colman, and Black Hamburg Grapes, grand Pitmaston Duchess Pears, and very fine Exquisite Peaches. Mr. McKelvie, Broxmouth Park, Dunbar, third.

For eight dishes of fruit Mr. McIndoe was placed first, some of the Grapes being rather deficient, though the exquisite Peaches, Doyenné Boussoch Pears, and Washington Apples were fine; Mr. Murray, Culzean, Ayr, second with better-looking fruits, and Mr. Morrison, Archerfield, Drem, third. Mr. Fairgrieve, Dunkeld, had the best collection of hardy fruit, and Mr. McIndoe the best collection of orchard house fruit. For six bunches of Grapes Mr. McKinnon was easily first with magnificent Alicante, Gros Maroc, Mrs. Pince, fine Black Hamburg, and well-coloured Muscat of Alexandria; Mr. Boyd, Callander House, Falkirk, second with all black Grapes, small in berry and of fine finish; and Mr. Murray, Polmont, whose splendid Muscat of Alexandria and Alicante would, with some judges, have given him a higher place. Mr. Boyd had first prize for four bunches; Mr. McHattie, Newbattle Abbey, the two best Muscat of Alexandria with splendidly coloured large clusters. Mr. Boyd had the two finest bunches of Black Hamburg, splendidly finished; Mr. Morrison had the best single cluster of Muscat of Alexandria; Mr. John Caldwell the best Alicante, a fine example; Mr. McKinnon the finest Gros Maroc; Mr. Murray grand Gros Colman; and Mr. Caldwell a fine cluster of Duke of Buccleuch, the best white of any other sort not named in the schedule. Mr. McIntyre, The Glen, had the two best Pine Apples and a single Smooth Cayenne; and Mr. Muir, Margam, the best Queen. Peaches were rather poor, Nectarines not large, and of Plums there was a fair display. Apples were very largely shown, Mr. Murray, Culzean, having the best collection of twelve sorts. Duchess of Oldenburgh, Stirling Castle, Irish Peach, Warner's King, Keswick Codlin, Ecklinville Seedling, Alfriston, were among the best of the Apples shown in large quantities. The best Pears in single dishes were Souvenir du Congrès, Doyenné Boussoch, Jargonelle, Marie Louise, Louise Bonne, and Beurré d'Amanlis. The best six varieties of Pears were shown by Mr. Cairns, The Hirsell, Coldstream.

Cut flowers were not very numerous; Gladiolus were in fair numbers, but not of the highest quality. Roses from Mr. Parlange, Helensburgh, very good. Mr. Pearson showed fine examples of Dahlias. Mr. Rushton, Corstorphine, showed twelve magnificent blooms of Madame Desgranges and G. Wermig Chrysanthemums.

The collections of vegetables were numerous, and the quality all

through good. For the Veitch Memorial medal and £7 the competition was very close, Mr. Tender being placed first, and Mr. Cairns, Mounteviot, Jedburgh, second. The Celery, Onions, Tomatoes, Cucumbers, Cauliflowers, and Leeks being especially fine in both collections. The Lyon Leeks shown by Mr. Cairns being considered among the finest examples ever shown. For the prizes offered by Messrs. Sutton and Sons, Reading, Mr. Bigham, Edgerton, was first, and Mr. McBean, Johnstone, second. The best collection of salads was staged by Mr. Milne, Sunnybank. In the singledishes of vegetables, Celery, Leeks, Onions, and Tomatoes were especially fine.

Of miscellaneous exhibits there was a large and excellent display. Among the more noteworthy was a fine collection of 120 varieties of Apples from Messrs. J. Veitch & Sons, Chelsea, about sixty dishes of Pears from the same firm, as also some beautiful Nephentes and cut herbaceous flowers. A table of over 400 varieties of Ferns from Messrs. Sale, Birkenhead, excited much interest as much on account of the healthy appearance of the plants as by the rarity and beauty of many of them. Messrs. J. Laing & Sons contributed examples of their fine Begonias. Local firms were represented by Messrs. Dickson & Co., Waterloo Place, who with plants staged an interesting series of Apples and many florist flowers. Messrs. J. Methven & Sons, Princes Street, had a beautiful assortment of decorative stove and greenhouse plants, while Mr. John Downie, Princes Street, had a large table of good Begonias; Munro & Ferguson showing cut herbaceous flowers. Messrs. Laing & Mather, Kelso, had many border and Clove Carnations and Gladioli; Mr. Campbell, High Blantyre, Carnations and Picotees; and Mr. Forbes, Hawick, a representative of collection of Hollyhocks, Dahlias, Antirrhinums, Pentstemons, &c. Mr. Devereil showed examples of Onions of great size, which attracted very much attention; and to Mr. Murray, Culzean, a first-class certificate was awarded for a large red seedling Onion named "Black Douglas." The Exhibition was attended by many thousands of people during the two days it was open, the weather being dull but fine.

EDINBURGH PLUM CONGRESS, 1889.

THE best varieties of Plums exhibited in the various collections were, taking the collections in the order in which they were staged, Gordon Castle, October Green Gage, Webster's Seedling, Aurora, and some others of his numerous collection of unnamed seedlings were the best in the lot exhibited by Mr. Webster, Gordon Castle Gardens, Morayshire; Mr. Forrest, Haddo House, Aberdeen, had Goliath, Jefferson, Washington, and Nectarine (very fine); Mr. Crosbie, Buchanan Castle, Stirlingshire, Jefferson, Kirke's, Magnum Bonum, and Victoria; Mr. Sutherland, Langwell, Caithness, Nectarine, and Victoria (very good for so far north); Mr. Smith, Cullen House, Banff, Lawson's Golden Gage, and Emperor; Mr. McLeod, Harvieston, Clackmannanshire, Washington, Coe's Golden Drop, and Magnum Bonum; Mr. Whitton, Glamis Castle, Forfarshire, Transparent Gage, Pond's Seedling, and Victoria; Mr. McIntosh, Paxton House, Berwick-on-Tweed, Magnum Bonum and Pond's Seedling, very fine; Mr. McKelvie, Broxmouth, Dunbar, Kirke's, Magnum Bonum, Transparent Gage, and Jefferson; Messrs. Dicksons and Co., nurserymen, Edinburgh, Grand Duke, Goliath, Webster's Golden Gage, Victoria, Cox's Emperor, Lawson's Golden Gage, Nectarine, Reine Claude de Bavay, and Transparent Gage; Mr. Dunn, Dalkeith, Transparent Gage, Jefferson, Kirke's, Coe's Golden Drop, Reine Claude de Bavay, Goliath, Belgian Purple, Pond's Seedling, and Prune Damson, Mr. McHattie, Newbattle Abbey, Victoria, Jefferson, Washington, and Lawson's Golden Gage, very fine; Mr. McKinnon, Melville Castle, Belle de Louvain, Pond's Seedling, Victoria, and Washington; Mr. Bowman, Pittendreich, Lasswade, Lawson's Golden Gage, extra fine; Jefferson, Pond's Seedling, Magnum Bonum, and Victoria; Mr. Taylor, Inveresk House, Musselburgh, Washington and Oullins Golden; Mr. Morrison, Jefferson, Victoria, Goliath, and Magnum Bonum (very fine); Mr. Williamson, Tarvit, Cupar Fife, Jefferson, Magnum Bonum, Washington, Pond's Seedling, and Goliath; Mr. Elliott, Blackadder, Berwickshire, Belgian Purple, Magnum Bonum, Lawson's Golden Gage, and Jefferson; Mr. Milne, Minto House, Roxburghshire, Goliath and Victoria; Mr. Watt, Priorwood, Melrose, Jefferson, Magnum Bonum, Goliath, Kirke's, and Transparent Gage; Mr. Thomson, Eildon Hall, Newtown, St. Boswell's, Green Gage, Jefferson, Magnum Bonum, and Lawson's Golden Gage (very fine); Mr. Gunnison, Kingsmuir, Peebles, Kirke's, Jefferson, and Coe's Golden Drop.

Mr. Thomson, Garvald House, Peebles, Goliath and Victoria; Mr. McKinlay, Blackwood, Lanarkshire, Goliath and Cox's Emperor; Mr. Angus, Dalzell, Motherwell, Kirke's, Jefferson, and Goliath; Mr. Brown, Abercainey, Perthshire, Coe's Golden Drop, Kirke's, Magnum Bonum, Victoria, Goliath, and Prince of Wales; Mr. Whitton, Methven Castle, Perth, Guthrie's Topaz (very fine), and Washington; Mr. Harper, Tullibelt, Perthshire, Coe's Golden Drop, Kirke's, and Cox's Emperor; Mr. Fairgrieve, Dunkeld, Caledonian, Pond's Seedling, Cox's Emperor, Victoria, Kirke's, Magnum Bonum, and Jefferson (all very fine); Mr. King, Blairdrummond, Doune, Perthshire, Cox's Emperor, Jefferson, and Magnum Bonum; Mr. McKinnon, Scone Palace, Perth, Brahy's Green Gage, Diamond, Pond's Seedling, and Kirke's (very fine); Mr. Reid, Solsgirth, Dollar, Goliath and Victoria; and Mr. McLennon, Castlewigg, Wigtonshire, Jefferson, Kirke's, and Coe's Golden Drop.

Among the collections sent from England the finest varieties were from Mr. Harris, Alnwick Castle, Northumberland, Kirke's, Victoria, Lawson's Golden Gage, Cox's Emperor, Prince Englebert, and Pond's Seedling; Mr. Clarke, Lowther Castle, Penrith, Magnum Bonum, Goliath, Kirke's, and Lawson's Golden Gage; Mr. Christie, The Castle,

Warwick, Jefferson, Belgian Purple, Pond's Seedling, Reine Claude de Bavay, and Magnum Bonum; Mr. Watkins, Pomona Farm, Hereford, Diamond, Magnum Bonum, Peach Plum, Pond's Seedling, Oullins Golden, Green Gage, Prince Englebert, and Cox's Emperor (all very fine); Messrs. R. Smith & Co., St. John's Nurseries, Worcester, Goliath, Coe's Golden Drop, Cox's Emperor, Diamond, Reine Claude de Bavay, and Magnum Bonum (large and fine); Mr. Smith, Mentmore Gardens, Bucks, Green Gage, Transparent Gage, Grand Duke (extra fine), Sultan, Mitchelston, Jefferson, Kirke's, Cox's Emperor, and Reine Claude de Bavay, with fine samples of the following Damsons—Shropshire, Worcester, Farleigh, Prune, and Mussel.

Mr. Alexander, Warley Place, Great Warley, Essex, had very fine Magnum Bonum, Goliath, and Jefferson; Messrs. Lane & Son, nurserymen, Berkhamstead, Herts, Jefferson, Prince Englebert, Sultan, Prince of Wales, Diamond, Pond's Seedling, Cox's Emperor, and Grand Duke, all large and very fine; Messrs. Veitch & Sons, Royal Exotic Nursery, Chelsea, Transparent Gage, Reine Claude Violette, Brahy's Green Gage, Reine Claude de Bavay, Lawson's Golden Gage, Frogmore Late Gage, Jefferson, Magnum Bonum, Prince Englebert, Pond's Seedling, Boulouf, and Decaisne, all extra fine, the last named two being little known varieties of great promise; Mr. Barron, Royal Hort. Society's Gardens, Chiswick, Belle de Septembre, and Poupard, extra fine, with interesting samples of the French Prune Plum, D'Agén, the true Prune Damson, the White Damson, Coe's Late Red Plum, Winesour Plum, and Royal Bullace; Messrs. G. Bunyard & Co., nurserymen, Maidstone, Kent, a very interesting lot of bearing branches of Plums and Damsons, including King of the Damsons (large and fine), the Old Sweet Damson (small, but sweet and pleasant), Crittenden Damson (very heavily with fruit), Reine Claude de Bavay, and Magnum Bonum; Mr. Rust, Eridge Castle Gardens, Sussex, Guthrie's Green Gage, Transparent Gage, Diamond, Pond's Seedling, Washington, and Grand Duke, all excellent, and grown at an altitude of 400 feet above sea level.

From Ireland were sent about half a dozen fine collections, containing many samples of considerable excellence, the most notable of which were from Mr. Warwick, Shanes Castle; Co. Antrim, Jefferson, Transparent Gage, and Magnum Bonum; Mr. Cumming, St. Helen's, Co. Dublin, Magnum Bonum, Goliath, and Victoria; Mr. Whytock, Coolatin, Shille agh, Co. Wicklow, Belle de Septembre, Prince Englebert, Coe's Golden Drop, Pond's Seedling, and Diamond; Mr. Cobban, Garbally, Ballinasloe, Co. Galway, Kirke's, Coe's Golden Drop, Goliath, Pond's Seedling, Jefferson, and Magnum Bonum; Mr. Richard Hartland, The Lough Nurseries, Cork, Reine Claude de Bavay, Decaisne (extra), Magnum Bonum, Archduke, and Kirke's.

BRIGHTON SHOW.—SEPT. 11TH AND 12TH.

SUSSEX is one of England's favoured counties as regards climate, and it is only fitting that horticulture should be represented in its best form, both in gardens and shows. For a considerable time the Brighton Exhibitions have been regarded as admirable examples of what provincial shows should really be—namely, displays of the local garden produce in competition, together with sufficient exhibits from a distance to prevent competitors becoming too restricted in their ideas of perfection. Of moderate extent, it has avoided the defects which frequently characterise the larger exhibitions, the most conspicuous being the admission of much inferior produce, simply with the object of filling classes and tent space. A carefully arranged schedule, fairly liberal prizes, and good competition have rendered the Show notable amongst those in the southern counties; but unfortunately in several years the attendance of visitors has not been proportionate to the merits of the display provided, consequently financial difficulties have occurred that have embarrassed the managers. The Secretary, Mr. Carpenter, has succeeded almost single-handed in reviving the Show more than once when it seemed that very unlikely another would be held, and he had the satisfaction last Wednesday and Thursday of seeing one of the best yet held in the rooms and ground of the Royal Pavilion. The weather also was most favourable, and we should be glad to hear that the receipts at the gates were sufficient to ensure a substantial balance.

Plants.—The two principal collections of specimen plants were from J. Warren, Esq., Handcross Park, Crawley (gardener Mr. Offer), who was first with twelve fine-foliage and eight stove and greenhouse plants, all well-known exhibition specimens, the Palms, Ferns, and Crotons of great size, and occupying much space in the lofty apartments of the Pavilion. Following in the same class were Col. Pepper, Milford Hall, Salisbury (gardener, Mr. J. Currey); and Mrs. Armstrong, Woodslea (gardener, Mr. Meahin), both of whom had well-grown plants. Sir A. Lamb, Beaufort, Battle (gardener, Mr. Portnell) exhibited capital examples of Ericas, gaining the chief award. *E. cinerithoides coronata* and *E. Aitoniana Turnbullii* being remarkable for their good training and abundance of flowers.

Groups are usually an important feature at Brighton, and on this occasion they also provided a considerable attraction, but there was a little falling off in the general quality as regards the groups of miscellaneous plants. Mr. J. Currey was adjudged the premier award for a fairly light arrangement of Crotons, Palms, Lilies, and Chrysanthemums, but a number of small and inferior plants had also been employed which greatly lowered the value of the group, so much indeed that many thought it was scarcely entitled to the position accorded it. In classes for groups of this character it is sometimes very difficult to distinguish between the respective merits of contending groups; and though it is advisable to encourage a light style of arrangement it is equally undesirable that a loose or careless style should be mistaken for

taste. Informality and naturalness are required, but not slovenliness, and exhibitors occasionally seem unable to distinguish between these extremes. Some also start well; they get the framework of the group worked out capably, but when it comes to the filling in all is spoiled; other perhaps give their greatest attention to the front or the back and the other portion having quite a distinct appearance and looking as if the plants had been huddled together in a hurry, which is usually the case if the time to be occupied is not carefully considered before starting and the work arranged accordingly. Examples of all these defects have quite recently come under notice, all from good exhibitors, who with a little more forethought might have readily avoided them. Then, too, when classes are provided for groups in which quality and effect have both to be considered, exhibitors are sometimes puzzled and rely too much upon the excellence of the plants they employ, neglecting the arrangement proportionately. The fact is, that anything approaching to what are termed "specimen plants" can seldom be employed with good effect in a group of moderate size, and even in the largest they usually have a heavy and disturbing appearance. At the same time weakly or insect-infested plants with discoloured foliage or with few, poor, or fading flowers should never be placed in a group for effect, even to "fill up;" they are certain to be noticed by any careful judges, and should reduce the chances of the exhibitor's success. In the class at Brighton noted above the second prize was awarded to Mrs. Armstrong, who had a group of which *Crotons*, *Lilium lancifolium*, *Palms*, *Ferns*, *Acalyphas*, and *Asparagus plumosus* were the leading features; and though some of the plants were rather large they were well and effectively arranged. Mr. G. Miles, Victoria Nursery, Dyke Road, was third, also for a good style of group, white *Lilies* and *Ferns* predominating, but a little more colour would have improved it.

The groups of *Ferns* always constitute a charming feature at this Show, and we have frequently commended the class and exhibits as worthy the attention of other societies. In so many gardens *Ferns* are now extensively grown for cutting purposes that it is not difficult to obtain sufficient for a group of fair size, and with comparatively few plants a most pleasing effect can be produced, particularly where some of the bolder looking broad fronded sorts are employed. Mr. Offer had the best exhibit, a diversified and fresh group with *Tree Ferns* at the back, a groundwork of *Adiantums*, and prominent raised corners of *Neottopteris* with rich green substantial fronds, and a few other distinct *Ferns* were scattered through the group. Mr. W. Miles, West Brighton Nursery, was a close second, having a large central specimen of *Nephrolepis davallioides* furcans, with smaller plants of *Adiantum* grouped around it. Mrs. Duddell, Queen's Park (gardener, Mr. Spottiswood) was third for a collection of *Adiantum cuneatum*.

Cut flowers have numerous classes devoted to them, and the exhibits produced an admirable display, proving how valuable these classes are in late summer and early autumn shows. With twenty-four bunches of stove and greenhouse plants Mrs. Gibson, Hill House, Saffron Walden (gardener, Mr. W. Archer), was awarded premier honours for excellent fresh and bright flowers of *Rondeletia major*, *Dipladenias*, *Ixoras*, *Allamandas*, *Lapagerias*, *Anthuriums*, *Statice*s, and *Tuberose*s. Messrs. Knight & Co. were second, also with good specimens. *Dahlias*, *Roses*, *Asters*, *Gladioli*, and hardy flowers were all good, Messrs. Paul & Son, Cheal & Son, Piper, Balchin, and R. Miller being the leading exhibitors. For three stands of flowers Mr. Rupert Miller, Shoreham, won the first prize for far the best contribution of the kind in the Show. A tall central stand was lightly filled with white *Anemones*, *Coreopsis*, white *Sultans*, tall *Grasses* and *Ferns*, the base consisting of yellow and white *Sultans*, white and scarlet *Cactus Dahlias*, *Coreopsis*, and foliage. The side stands were much smaller, chiefly containing *Lilium lancifolium* and yellow *Sultans*. Mr. G. Miles and Mrs. J. Lewis, Preston Park Avenue, followed. Messrs. Perkins & Son, Coventry, were the chief exhibitors of wreaths and bouquets, showing their usual tasteful productions.

Fruit was well represented in numerous classes, and though some of it was probably seen at the Crystal Palace Show recently, and consequently had a slightly "travel stained" appearance, there was abundance of fresh exhibits. Some of the most successful exhibitors were Dr. Withers Moore (gardener, Mr. Godby), Mr. C. J. Goldsmith, Beckenham, Mr. Spottiswood, Mr. Osman, and Mr. Duncan. Messrs. Sutton & Sons, Reading, offered prizes for vegetables, which induced good competition, and there were also numerous non-competing exhibits of plants.

NEWCASTLE-ON-TYNE.—SEPTEMBER 11TH, 12TH AND 13TH.

THE Durham, Northumberland, and Newcastle-upon-Tyne Botanical and Horticultural Society held their autumn Exhibition on the above dates in the Leazes Park, Newcastle. The Show was held nearly two months later this year in order to take place during the meeting of the British Association, and the latter behaved most handsomely to the Society by offering £100 for special prizes, which made a most substantial schedule. The officers of the Society were most hopeful of securing excellent weather, as September in the north up to the very morning of the Show was all that could be desired, but then rain came down in torrents nearly all day, to the disappointment of the Committee, exhibitors, and general public alike. The Committee and the Secretary, Mr. J. J. Gillespie, who is hard-working, painstaking, and courteous to all whom he comes in contact with, were much sympathised with. The weather improved before the close of the Exhibition, but was dull and threatening on Friday, and the Society are stated to have lost upwards of £200.

The Show was held in four large tents placed together and the sides taken out, so that visitors could see all over the Exhibition upon entering it. At night it was illuminated with the electric light, which was much admired, and the foliage plants, especially the magnificent *Dracanas* and *Crotons* of Messrs. Little & Ballantyne, were seen to the best advantage. The excellence of the staging arrangements as regards the flowering and foliage plants added greatly to the effect of the Exhibition, and the staging Committee, Messrs. Balfour, Wilson, and Gascoigne, who were indefatigable in the discharge of their duties, deserve much credit. Referring to the cultural excellence of the exhibits, it may be safely said that the Society has never held an Exhibition of a more satisfactory character; in fact, so far as it went it was one of the best in the country. Cut flowers of all kinds, embracing *Dahlias*, *Gladioli*, *Asters*, *Carnations*, herbaceous flowers, bouquets, and epergnes, were a grand display. *Hollyhocks* also were shown in great quantities, and many were pleased to see these old favourites again prominent on the exhibition table.

Specimen stove and greenhouse plants were better than they are now seen at most southern shows, although far behind the giants which were exhibited a few years ago by Messrs. Mould, Legg, Pewsey, Ciper, and others. The fact is, huge exhibition plants are losing popularity, and perhaps the time is not far distant when they will cease to be an important feature of horticultural exhibitions. They are giving place to bright, free, and tasteful grouping of ordinary indoor stock; and though there is less to astonish the inexperienced in the new order of things there is more to please, to interest, and to instruct. It is a great defect in the Newcastle schedule that there is no class for groups. They are looked for now both by cultivators and by the public, not only at urban, but at country exhibitions, and if Newcastle is to be considered the centre of north-English horticulture it must weigh these facts before another Exhibition comes round. Fruit was admirably shown; indeed, culturally considered, it was the best portion of the Show. Very liberal prizes were offered for collections, and close competition on the part of nearly all the best northern growers produced a display of great extent and of very high quality; indeed, with recollections of the fine display at the Crystal Palace on a recent occasion fresh in the mind, the gardeners of the north appeared thoroughly capable of holding their own with their confrères in the south had it been possible to meet in competition. Grapes were magnificently shown. They were as well, if not so extensively, staged as at the Crystal Palace, and were greatly admired. There was, however, some unpleasantness caused by the decision of the Judges in one or two classes.

There were no classes for vegetables, though a horticultural show can hardly be considered complete without them.

PLANTS.

For eight plants in bloom, £20 in cash and the Royal Horticultural Society's silver Banksian medal were offered. The latter went with the first prize of £8 to Mr. F. Nicholas, gardener to the Earl of Zetland, Upleatham, for good, well-balanced plants, not large, but healthy, clean, and profuse in bloom. They included *Ericas* *Marnockiana*, *emula-austriaca*, and *grandiflora*, *Stephanotis*, *Bougainvillea glabra*, and *Dipladenia amabilis*, the latter shown in excellent colour and extremely fresh. Mr. Nicholas is a new exhibitor, and has made a most creditable and encouraging beginning. There is no doubt that at no distant date he will make a name in the horticultural world. Mr. T. Suffield, gardener to Mrs. Kitching, Elmfield Gardens, Darlington, was second with fresh good plants, including capital specimens of *Allamanda Hendersoni*, *Lapageria rosea alba*, *Ixora Williamsi* (very good), *Clerodendron Balfourianum*, *Oncidium flexuosum* (very fine indeed), *Dipladenia amabilis*, and *Erica Marnockiana*. Mr. J. Morris, Park Road, Felling, was third, his best plant being a very fine *Vallota purpurea*. For eight foliage plants the Society offered prizes of £6, £4, £2, and £1 respectively, but they only brought three competitors, Mr. E. H. Letts, gardener to the Earl of Zetland, Aske Hall, being placed first with his well-known *Palms*, *Encephalartos Vroomi*, *Kentia australis*, *Cycas circinalis*, and *C. revoluta*, *Croton Johannis* (very good in colour), *Gleichenia rupestris glaucescens* and others. Mr. J. McIntyre, gardener to Mrs. Gurney Pease, Woodside, Darlington, was second with *Croton interruptus angustifolius*, *Kentia Belmorcana*, a grand *Cycas revoluta*, and *Croton Sinitzianus*. Mr. Suffield was third. For six *Ferns* Mr. F. Nicholas was first with *Dicksonia antarctica leucostezia*, *Pteris scaberula*, *Lomaria zamiaefolia*, and *Gleichenia rupestris*; Messrs. McIntyre and Suffield following. *Ericas* were rather weak this year, Mr. E. H. Letts was first. *Liliums* and *Tuberous-rooted Begonias* were shown best by Messrs. Watson and Garret.

TABLE DECORATIONS.

Large plants were as usual an interesting display, and brought forth six competitors, Messrs. Suffield, McIntyre, and Johnston receiving the awards. Many *Palms* and *Dracanas* were shown in small pots, all effectively draped with *Lycopods*. Six competed with a vase or epergne for drawing rooms, and as epergnes always form a strong feature at the autumn exhibition, great interest was evinced in those staged. Mr. Jos. Turton, gardener to Thos. Hodgkin, Esq., Benwell Dene, was first with a neat arrangement of a Marsh stand, the top tiers arranged with *Centaurea Cyanus*, *Lilium Harrisii*, *Ixora*, &c. The next tier *Eucharis amazonica*, and the bottom *Allamandas* and *Ixoras*, all effectively arranged, and margined with *Adiantum gracillimum*, *Davallia Mooreana*, &c. This was really a very good epergne, the base, if anything, rather heavy for the light way the higher tiers of flowers were arranged. The second prize was given to Messrs. Webster, Sunderland,

for a well arranged epergne containing some choice flowers. Mrs. Oliphant, The Green Market, Newcastle, was third. For a basket of cut flowers Messrs. Perkins & Son, Coventry, were placed first. The handle was effectively covered with *Asparagus plumosus*, and the basket contained choice Orchids, such as *Cattleya Mendelli*, *Odontoglossum Alexandre* and *Caladium argyrites* used with much effect. *Maréchal Niel* Roses and white variegated *Acers* also told well. Baskets are almost a new feature at Newcastle, but they form a pleasing way of exhibiting flowers. Nine were shown, all tastefully arranged.

There were eight bridal bouquets, Miss E. Armstrong Bennett, a young local lady, was placed first, defeating Messrs. Perkins & Son, Coventry, an achievement of which she may be proud. She had *Dendrobium Dearth*, white *Asters*, *Stephanotis*, *Tuberoses*, *Pancratiums*, *Gardenias*, white *Lapageria*, *Rose Niphetos*, and *Eucharis amazonica*. This was a beautiful bouquet, well arranged, and the Fern evenly disposed all over it. Messrs. Perkins was also a charming bouquet, but rather too heavy with Fern. There seems to be a growing taste for increasing the size of bouquets; those at Newcastle were more than 18 inches high and 18 inches in diameter; these are too ponderous, and would be a heavy load for a bridesmaid to carry to church. In the class for hand bouquets there were nine entries. Messrs. Perkins & Son regaining their usual position of first with a beautiful bouquet, containing *Cattleya Mossiae*, *Pancratiums*, *Oncidium flexuosum*, *Lapagerias*, and *Tuberoses*. Miss E. Armstrong was second with a very good bouquet, evincing much skill and taste; and Mr. J. Jennings third. The ladies' sprays, also only recently shown at Newcastle, brought out fifteen competitors, Miss E. Armstrong being again first; she used *Odontoglossum Alexandre* and *O. flexuosum*, with *Adiantum gracillimum*. Mrs. Oliphant was second with *Tuberose*, *Zygopetalum Mackayi*, *Erica Marnockiana*, &c. Messrs. Perkins were third with *Odontoglossum Alexandre*, *Maréchal Niel* Rose, *Rhododendron Princess Royal*, and *Bouvardia*.

CUT FLOWERS.

For the buttonhole prizes there were thirty entries, the first falling to Mr. J. Battensby, Swallow, who used *Dendrobium thyrsiflorum*; *Bouvardia*; and a *Rose*, *Madame Falcot* type; and *Adiantum gracillimum*. Of twenty-four Dahlias, distinct, Fancies excluded, six lots were produced, the first prize going to Messrs. Clark & Son for a good stand of *Queen of the Belgians*, *William Keith*, *Rev. J. Camm*, *Ethel Britton*, *Harrison Weir*, *George Barnes*, *George Rawlings*, *Goldfinder*, and *Earl of Ravensworth* as their best blooms. Mr. R. Walker, Low Fell, Gateshead, was second with a very fine stand, including *Harry Keith*, *James Cocker*, *W. Stark*, *R. T. Rawlings*, *Clara*, and *Henry Walton*. Mr. J. Spoor, Swallow, was third. For twelve Dahlias, Fancy, the veteran exhibitor, Mr. Walker, was a good first, the best blooms being *Grand Sultan*, *Peacock*, and *Mrs. Saunders*. Messrs. H. Clark & Son were second with *Mrs. Saunders*, *Geo. Barnes*, *Hugh Austin*, *Lotty Eckford* (beautifully marked) as their best. For twenty-four Hollyhocks the Society offered £10 in prizes. Seven excellent collections were staged, Mr. Geo. Finlay, East Layton Hall, Darlington, being first with full grown, good centred, and large flowers, the best varieties being *L. Godin*, *Favourite*, *W. E. Gladstone*, *Lord Warkworth*, *Queen of Yellows*, *Peri*, and *Lord Dalkeith*. Mr. Geo. Rogerson, North Middleton, Morpeth, was second, with good flowers of *Cremorne*, *Leviathan*, *Maggie Bain*, and *Hercules*. *Gladioli* were shown extremely well. Mr. Alex. G. Campbell, Cove Gardens, Gourock, N.B., was first with splendid spikes, some containing sixteen flowers each, of *Le Phare*, *Crépuscule*, *Atlas*, *Conquerant*, and *Camille* amongst others. Messrs. Harkness & Son, Bedale, were second also with very good spikes. With twenty-four Roses, not less than twelve varieties, Messrs. J. Cocker and Sons, Aberdeen, were first, having very good fresh blooms for the time of year; *Madame Eugene Verdier*, *J. S. Mill*, *La France*, *Etienne Levet*, *Souvenir de Berthe*, and *Maréchal Niel*, were amongst the best. Messrs. Harkness & Son were second, and Messrs. Perkins & Sons third. Bunches of hardy herbaceous border flowers were in themselves a magnificent display. They have always been well shown at Newcastle, but on the present occasion they surpassed all previous displays, and received the admiration of every visitor, many of whom were astonished that so many fine flowers could be grown out of doors. Messrs. Harkness were first here with a fair collection, including large bunches of *Gaillardia grandiflora*, *Lilium Harrisii*, *Delphinium Mont Blanc*, *Helianthus maximus plenus*, *Harpalum rigidum* (very fine), *Papaver nudicaule*, *Anemone Honorine Jobert*, the ever charming *Senecio pulcher*, *Rudbeckia Newmanii*, *Coreopsis lanceolata*, *Chrysanthemum Madame Desgranges*, *Triteleia aurea*, *Erigeron speciosa*. Some splendid *Phloxes* named *Madame Desgranges*, a charming white, *Tritonia aurea*, and last two single *Pyrethrums*, marvellous for their colour, named *John Holborn* and *Hamlet*, the latter a lovely purple flower. This stand rivetted the attention of every lover of flowers. Mr. J. Short, Darlington, was second with a very good stand, in fact, no bad stand was exhibited. *Globe* and *Feathered Asters* were a very beautiful display, the flowers being large, finely formed, and of good colour. Mr. Wm. Sanderson, a veteran grower, was first in each class with splendid flowers. For twelve Carnations, also six Carnations (self or Clove), Mr. J. Dixon, senior, was first, and Mr. D. Owbridge won with *Picotees*. Mr. J. Garret won with *Zonal Pelargoniums*, having very fine trusses of *Lord Tredegar*, *Grand Duke*, *Princess of Wales*, and *Lizzie Brooks*. *Marigolds* and *Pansies* were also strongly competed for, Mr. Battensby winning with *Fancy Pansies*, and Mr. Geo. Davison with *Shows*, Messrs. A. Kerr & Son winning with *Marigolds*. For twelve bunches of cut flowers Mr. H. Johnston was first with *Ixora Williamsii*, *Eucharis*

amazonica, *Lapageria alba*, *Erica Marnockiana*, *Celosia*, and *Odontoglossum grande*, very good. Three lots were shown.

FRUIT.

We now come to the most important feature—fruit, of which, as before stated, there was a splendid display. For twelve dishes £17 was given by the British Association. There were four competitors. Mr. J. McIndoe, Hutton Hall, was deservedly placed first for a very meritorious collection. He had *Golden Champion* and *Gros Colman* Grapes finely finished, berries large, especially the latter, a *Queen Pine*, about 4 lbs. in weight; *Prince of Wales* Nectarines, *Pitmaston* Duchess Pears, *Scarlet Premier* Melon, *Ribston Pippin* Apples, *Magnum Bonum* Plums, and *Negro Largo* Figs. Mr. J. H. Goodacre, gardener to Lord Harrington, Elvaston Castle, Derby, was second, with *Muscat of Alexandria* and *Black* *Hamburgh* Grapes, *Queen Pine*, *Barrington* Peaches, *Hero of Lockinge* Melon, and *Garibaldi* Strawberry as his best; Mr. J. Hinks, Lambton Castle, being third with *Canon Hall* and *Alnwick* Seedling Grapes in good condition, *Queen Pine* rather too ripe, *Jefferson* Apple, *Royal George* Peaches, and *Beurré Diel* Pears of enormous size, about 22 ozs. each. Mr. Hunter has had them this year over 32 ozs. For eight dishes Mr. Goodacre was first with *Muscat of Alexandria* and *Alnwick* Seedling Grapes, both well shown; *Luscious* Melon, *Violette* *Hâtive* Nectarines, *Washington* Plums, *Barrington* Peaches, *Morello* Cherries, and a *Queen Pine* about 3 lbs. in weight. Mr. J. Hunter was second with two fine bunches of *Canon Hall* and *Black Alicante* Grapes, the bunches quite 18 inches long; *Pitmaston* Duchess Pears, *Noblesse* Peaches, and a *Queen Pine*. Mr. R. Westcott, Raby Castle, was third, *Black* *Hamburghs* and *Muscat of Alexandria* Grapes, *Barrington* Peaches, and *Beurré Joubert* Pears being his best examples. For four dishes, Pines excluded, Mr. R. Westcott was first with *Muscat of Alexandria* and *Black* *Hamburgh* Grapes (well finished), *Barrington* Peaches, and *Best of All* Melon. Mr. J. McIndoe second with *Alnwick* Seedling Grapes, *Scarlet* *Flesh* Melon, *Princess of Wales* Peach, and *Humboldt* Nectarine well shown. For six dishes of hardy fruit Mr. J. Short was first, *Jargonelle* Pears, *Victoria* Plums, and *Morello* Cherries being excellent.

Grapes were a grand display. For six bunches not less than three varieties, six competitors entered, Mr. J. Potter, gardener to Wm. Parkin Moore, Esq., Whitehall, Carlisle, being adjudged first. He had *Buckland's* Sweetwater, magnificently finished, and of a clear amber colour. *Gros Colman*, *Black Alicante*, and *Muscat of Alexandria*, averaging from 3 to 4 lbs. each. They were an even and admirable lot. Mr. J. Hunter, Lambton Castle, was placed second with *Canon Hall*, *Gros Guillaume*, and *Muscat of Alexandria* as his best, and Mr. J. Duncan, Water Priory, third with *Black Alicante*, *Lady Downes*, and *Muscat of Alexandria* in good condition. Mr. J. Witherspoon, Chester-le-Street, also showed in this class, but the Grapes were not considered by the Judges ripe enough to receive a prize. They were well grown large bunches, with good shaped berries. For two bunches of *Black* *Hamburgh* Mr. C. Portsmouth, gardener to the Hon. and Rev. F. R. Grey, Morpeth, was first with superior bunches from 3 to 4 lbs. each, well coloured and the berries large, Messrs. Luck and Cowperthwaite following. For *Black Alicante* Mr. Nicholas was deservedly placed first, Mr. Duncan second, and Mr. Bell third.

For two bunches of *Black* Grapes any other sort, Mr. J. Witherspoon was first with *Alnwick* Seedling, about 2½ to 3 lbs. weight, and well finished, Messrs. Bell and Nicholas following. Mr. J. Potter was first with *Muscat of Alexandria* in good condition, also with *Buckland* Sweetwater, magnificent clusters, well finished, and splendidly coloured, Messrs. Hunter and Cowperthwaite following with *Muscats*, and Mr. Witherspoon with *Buckland's* Sweetwater. White Grapes of any sort brought Mr. J. McIndoe to the front with *Duke of Buccleuch*, and he was first for the heaviest bunch of Grapes with *Gros Guillaume*, weighing about 6 lbs.

Ten Melons were staged, the first prize falling to Mr. J. Potter with *Blenheim* Orange. For Peaches Mr. J. McIndoe was first with *Belle-garde*, and also first for a dish of *Pitmaston* Orange Nectarines. Currants and Cherries were also shown very well indeed. For twelve dessert Apples Mr. J. McIndoe was first, and Mr. J. Hunter second, his Apples being much larger and more finely coloured than the winning lot. This and other judgments in the Apple classes gave good fruit growers much surprise. Mr. McIndoe was also first with cooking Apples, and Mr. J. Hunter second. Mr. J. Hunter was first with a fine lot of Pears, including *Beurré Diel*, *Duchesse d'Angoulême*, and *Belissime d'Hiver*. Eleven lots of Tomatoes were staged, Mr. D. T. Bull of *Alnwick* winning the first prize with large well-formed fruit.

In the B division, nurserymen excluded, £5 and the Veitch Memorial medal for six plants in bloom were won by Mr. John Morris, Parkgate, Felling, Allamanda Hendersoni, *Lapageria rosea*, *Dipladenia amabilis*, *Erica Marnockiana*, and *Bougainvillea glabra* being good. For *Ericas* Mr. E. H. Letts was first with *Turnbulli* and *superba*. Mr. J. McIntyre won with six exotic Ferns, showing *Gleichenia rupestris glaucescens*, *Adiantum cuneatum*, and *A. gracillimum*, and *Davallia bullata* admirably. *Fuchsias* were also shown remarkably in this class. For a basket of cut flowers Miss E. Armstrong was first, and for a bridal bouquet Mrs. Oliphant won with one not quite so large as was shown in the corresponding class, but well put together, with very good flowers, and Miss E. Armstrong followed up her former success by taking first prize with a hand bouquet. For *Asters* (*Globe*) and *Gladioli* Mr. A. G. Brown, Whitburn, was first with very good flowers. Messrs. W. Sanderson and W. Hutchison won with *Asters*, and Mr. T. Flowdy was first for *Zonal* *Pelargoniums* and *Picotees*; Mr. G. Dixon, sen., won with *Carnations*.

For Pansies, Show and Fancy, Mr. Geo. Davison and Mr. George C. Murray were the respective winners. For six bunches of stove and greenhouse cut flowers Mr. H. Johnston was first.

Great credit is due to the local florists and nurserymen for sending plants not for competition. Messrs. Wm. Fell & Co., Hexham, sent a very fine collection of *Coniferæ*, finely coloured and well grown, including *Retinospora plumosa*, 6 feet; *Retinospora plumosa aurea*, *Juniperus chinensis aurea*, *Retinospora variegata plumosa argentea*, *Abies Englemanni* and *gloriosa*, and *Osmanthus ilicifolia*; *Cupressus Frazeri*, and *Hydrangea paniculata*, which is quite hardy; also a very fine collection of herbaceous plants in bloom. Mr. W. R. Armstrong exhibited Palms, Ferns, Eulalias, Lycopods, and other useful decorative plants. Messrs. Little & Ballantyne, Carlisle, exhibited a fine lot of half-specimen Crotons, including Queen Victoria, Ruberrima, and others, also seedling Begonias with very large flowers. Messrs. Jos. Robson, Hexham, showed hardy and useful *Coniferæ* of choice varieties. Messrs. Harkness, Bedale, had a unique and choice collection of herbaceous flowers similar to those described before. Mr. J. W. Tate, Florist, Sax's Gardens, exhibited plants suitable for house decoration, and Mr. W. J. Watson, nurseryman, Newcastle, a basket Virginia Creeper, white variegated, called *Ampelopsis variegata*, which should contrast well with Veitch's. Messrs. Stuart & Mein, Kelso, had two stands of French Marigolds and some beautiful Asters. Messrs. Kent and Brydon, Darlington, also showed a mixed stand of cut flowers, consisting principally of herbaceous plants.

After the judging was over the Committee, Judges, and other gentlemen had luncheon in an adjoining tent. Mr. Alderman Hooper of York was present with a deputation from the York Gala. The new Chairman of Committee, Councillor Baxter Ellis, presided, and was supported by the Mayor of Newcastle, Sheriff, Professor Flower, President of the British Association, Canon Loyd, and Mr. Alderman Lucas, Mayor of Gateshead. It is to be hoped that the Committee may have better weather another year, and recoup their heavy loss of the last two years, for the zeal and energy displayed by the Committee are worthy of success.

FRUIT FORCING.

PEACHES AND NECTARINES.—*Lifting Trees in Succession Houses.*—When the growth is too free, the crops not being satisfactory, the trees may be root-pruned or lifted as soon as the foliage shows indications of falling. If judiciously performed this will check their vigour and induce short-jointed fruitful wood. Any lifting or root pruning should be performed before the leaves fall, affording a good watering afterwards, mulching with a few inches thickness of short manure, and syringing the trees each evening for a few days. The trees will soon produce young active feeders.

Late Houses.—Trees of those very fine varieties, Princess of Wales, Barrington, Sea Eagle, Gladstone, Lady Palmerston, Walburton Admirable, the Nectarine Peach, and Comet, are now ripening; indeed, are ripe, the fruit being fully a fortnight to three weeks earlier than usual in the same houses and conditions as obtained in previous years—viz., been freely ventilated, kept as cool as possible through the hot weather by those means, well watered at the roots through a good surface mulching, and the foliage kept clean and healthy by forcible syringings. The trees must now have the benefit of a free circulation of air, utilising sun heat by keeping the ventilators closer than usual, or with ventilation in the early part of the day the temperature may be allowed to run up to 80° or 82°, which will do more to ripen the fruit and wood than sharp firing in dull weather. A somewhat drier condition at the roots is desirable when the fruit is ripening, but they must not be allowed to suffer for want of it so as to affect the foliage, and though the trees are not to be syringed an occasional damping will greatly tend to improve the health of the foliage. In dull wet weather a gentle heat in the pipes will be serviceable in securing the temperature essential to finishing the fruit and allowing a circulation of air.

Unheated Houses.—Induce ripening by a somewhat dry atmosphere. Make the most of sun heat by allowing a considerable advance under its influence, closing early, but providing a little top ventilation before night. Keep the wood thin, cutting away any gross growth, and shorten any safty shoots to 12 or 15 inches, and keep all laterals closely pinched to one joint.

CUCUMBERS.—Keep young plants well up to the glass to insure a sturdy growth, and pinch out the growing point at the second leaf if the plants are to be trained with more than one stem. It is important whether the plant are to have one or more stems that the laterals up to the trellis be rubbed off as soon as discernible, leaving the leaves, when they may be allowed to make side shoots for bearing. Continue the preparation of fermenting material where such is employed for bottom heat. Manure will require to be turned over about every three or four days, while tan need only be turned once, and that as soon as it is fairly

warmed through. In forming the beds whatever material is employed tread it well down. Give a light syringing only in the early part of the afternoon on bright days, but moderate moisture must be secured by sprinkling in the morning every available surface, and damping before nightfall. Maintain the temperature at 70° to 75° by artificial means, falling 5° through the night, and allowing an advance to 80° or 85° to 90° from sun heat, closing at 80°.

In pits and frames the temperature must be maintained by renovating the linings as necessary, and employing night coverings. Water very carefully, and sprinkle the foliage only on bright days. Keep the foliage thin, removing bad leaves and exhausted growths, and husband the sun heat as much as possible by early closing.

MELONS.—The latest plants are now well up the trellis, having been stopped when they extended two-thirds across. We grow all our Melons in houses on the single cordon system—i.e., the plants have all the laterals rubbed off up to the height of the trellis, and then every alternate one on opposite sides of the primary, stopping it when two-thirds across the trellis. The laterals show fruit blossoms at the second or third joint; if not, the laterals are pinched at the second joint, relying on the sub-laterals for the show of fruit. If the plants are weak and there is no hurry for the fruit remove all staminate and pistillate flowers on the laterals, stopping at the second or third joint waiting for fruit on the second or sub-laterals, which is an advisable plan where time is not a consideration, and a full crop and large fruit is required. We generally contrive to have both methods in the same house, which gives a longer succession of fruit—viz., plants allowed to fruit on the first laterals; those give two to four fruits per plant, and those that fruit on the second or sub-laterals four to six fruits each, the latter being a fortnight to three weeks later. As we have to maintain a succession daily from May to November inclusive the plan is an excellent one. A rather dry condition of the atmosphere with a little ventilation so as to insure a circulation of air is advisable, with a bottom heat of 80° to 85°, and impregnating the blossoms after they become fully expanded is advantageous to a good set. Do not earth up the roots until after the fruits are set and swelling. Fire heat will be necessary to maintain a temperature of 70° to 75° by day artificially, rising to 80° to 85° from sun heat, losing no opportunity of closing early, so as to run up to 90° or 95°. Be sparing of the syringe, only use it for damping in the morning and afternoon, syringing the foliage only on bright days and in the early part of the afternoon. Water at the roots only when necessary, using liquid manure to assist in swelling the crop, giving a thorough soaking when needed. Sprinkle all available surfaces with liquid manure, as we find this highly beneficial to the foliage, but a better plan is to sprinkle the surface of the border with a few fresh horse droppings about twice a week, and a little soot. We go a little further—viz., give each plant a handful of dissolved bone (superphosphate of lime), but we use no manure in the soil, except some lime rubbish and charcoal refuse, if they can be termed manures.

Considerable attention is necessary with plants swelling their fruits in guarding against canker and to prevent the fruit cracking. Fresh slaked lime applied on the first appearance of canker will subdue it, repeating it as necessary. A lessened supply of water both at the roots and in the atmosphere, particularly the latter, is the proper remedy for cracked fruits, or cutting the shoot half way through a few joints below the fruit in the case of very vigorous plants. Fruit ripening should have a little air constantly, with a temperature of 70° to 75°, and as much more as can be had from sun heat under 100°, with a corresponding increase of ventilation, but the fruit as soon as there is the least indication of the footstalk parting from it, even earlier than that if the fruit is expected to keep, and place it in a light and moderately airy fruit room. They will have more flavour and be more mellow than fruit allowed to bake on shelves in the sun.

Wet the foliage of plants in pits and frames as little as possible, and water only at the roots to prevent flagging. Renew or renovate the linings to finish off the crop directly the heat is found to be on the wane, and employ a covering on cold nights. In dull damp weather, and especially at night, leave a little ventilation. A little tilting of the lights at the back will allow the pent up moisture to escape, it will improve the quality of the fruit, and may prevent its cracking. Keep the foliage thin and the fruit well raised to the light.

KITCHEN GARDEN.

LIFTING AND STORING MIDSEASON POTATOES.—Many of the main crop or midseason Potatoes are now ripe, and advantage should be taken of good weather to lift and store them. Our plan is to dig up a good quantity on the morning of a fine day, and after being exposed for a few hours all that are to be stored for use are placed under cover, where they may remain for a day or two until quite dry, when they are either put in a dark shed or into clamps in the open, the object throughout being to prevent them becoming green. The seed tubers are next gathered, and are medium sized. These are not kept from the light, but great care is taken that they are well formed and free from disease.

OPEN AIR TOMATOES.—The wet, dull weather experienced near the end of August checked the development of these for a time, but of late they have been improving, and by exposing the whole of the fruit as much as possible to the sun they will make much progress. As very small fruit at the points of the shoots will not ripen, these should be cut back to the larger fruits, at the same time the foliage should be freely removed. Should the weather be unfavourable and any spare frame lights are disengaged, place these over the Tomatoes on the walls, and ripe fruit may be produced where it would otherwise remain green.

Liquid manure made from guano is the best stimulant that Tomatoes can have on and after this time.

AUTUMN SOWN CAULIFLOWER.—Some approve of sowing early kinds of Cauliflowers in the autumn for producing the first crop in spring, and in all such cases the seed should be sown at once. It is better to have small than large plants to winter, as the latter are liable to "button" in spring. A frame in a sunny part of the garden with good soil in it up to about 9 inches from the top is suitable for raising the plants. Sow the seed thinly, cover an inch or two deep, make the surface firm, but do not place on the lights until severe weather compels this, as the hardier and more dwarf the plants can be kept in early winter the better do they withstand severe frost. If the seed is sown thickly the plants may soon become crowded if not thinned when in a small state. A two-light frame of good plants are as many as are required for the majority of gardens.

LIME IN THE KITCHEN GARDEN.—As our vegetable quarters became vacant last autumn we give them a good dressing of lime, and the crops of all kinds that have been produced since have been the most luxuriant and remunerative we have secured for many years. Like many others our ground has been over-dressed with leaf soil and vegetable refuse, and the lime is beneficial in all such cases.

MUSHROOMS.—Since the end of June we have been gathering abundance in the fields, but attention must now be given to artificial beds. The manure should not be allowed to dry too much, as it retains the heat much better and longer when moderately moist. We have just spawned a large bed that will produce plenty of Mushrooms from the beginning of November until after Christmas, and by that time others will be bearing. Spawn is inserted when the heat is at 85°, and sometimes 90°. This causes it to run freely, and the result is a more even crop than when spawned at 75°, the Mushrooms then coming up in clusters. We mix turfy soil with the manure, as we note that some of our finest clusters spring from the pieces of turf; also spread a little hay over the beds to prevent them from becoming too dry, as if this occurs it is difficult to make it quite moist again.

DEAD LEAVES ON WINTER GREENS.—There are many dead leaves on the winter greens, such as Brussels Sprouts and Savoys, and as these prevent the air and sun hardening the stems for winter they should be cleared off, and the plants will show the benefit of it when they have to pass through any severe weather.

MATURED CAULIFLOWERS.—These are plentiful at present. Veitch's Autumn Giant is most serviceable, and all who value autumn Cauliflowers grow it. When the supply of heads exceeds the demand they may be cut off before they have become too old for use with about 10 inches of stem attached, then inserted in damp leaf soil or sand in a partially dark but airy place. Under these conditions they will remain firm and good for three weeks.

PLANT HOUSES.

Hyacinths.—Bulbs should be potted at intervals of three weeks until the end of October when required for decoration over as long a period as possible. Homerus (single red) will be found the most suitable for very early flowering. The spike is not large or crowded with bells, and consequently opens better than any other variety under early forcing. The colour of the flower at first is bright, but it quickly fades, which is its only fault. For early work, however, it cannot well be dispensed with. La Tour d'Auvergne, double white, is perhaps the earliest of all Dutch varieties, and will precede Homerus by a few days. The pure white double bells of this variety will be invaluable for all who have bouquets, buttonholes, and sprays to make; the bells when wired are very suitable for this purpose. Charles Dickens is the earliest of the single blooms, but it is fully ten days later than those named—in fact, several single varieties of various shades of colour will flower about the same time as Charles Dickens. For ordinary decoration the following are amongst the most useful:—Single white: Alba Maxima, Madame Vander Hoop, Alba superbissima, Grandeur à Merveille, Baroness Tuyll, and Grand Vedette. Single blues: Baroness Tuyll, Grand Lilas, Argus, Marie, Uncle Tom, and Charles Dickens. Single red: Robert Steiger, Gertrude, Norma, Amy, Gigantea, and Madame Hodson. Yellow: Ida. Doubles—red: Lord Wellington and Waterloo. Blue: Blocksberg and Laurens Koster. No better white than the one named can be selected, and if potted at different times will be found useful throughout the season. In potting single bulbs may be placed in 4½-inch pots, and three in 6-inch. One good crock only will be necessary for drainage, with a little of the roughest of the compost over it. The top of the bulb should just be visible when potting is completed. The soil should be pressed only moderately firm. The soil may consist of equal quantities of good loam that has been stacked some months, with about one-seventh of manure added at the time of stacking, and old soil from the potting shed, with the addition of about one-fourth leaf mould. A little coarse sand may be necessary, but this depends upon the texture of the loam. Carefully avoid the use of manure in a fresh state.

Tulips.—Place these in pots and boxes in quantity, according to the demand. For early flowering it is best to have Tulips thickly in boxes or pans, and then lift, and repot them when they come into flower. Early in the season Tulips flower very irregular, and it is difficult to have good pots without they are made up. Early in the year there is no perceptible difference in the lasting properties of the flowers, whether grown in the pots or lifted and placed thickly into them. For early work Duc Van Thol is the most useful, the scarlet form only being worth the trouble of boxing. The best of all whites and the earliest is Pottebakker. The flowers are large, sweet, and of the purest white. Early in the season, before being fully expanded, the flowers are almost

as valuable for wreaths and bouquets as the buds of Niphetos Rose, which they much resemble. Chrysolora is the earliest of the yellows. For later flowering they are placed five or six, according to their size, in 5 and 6-inch pots. Other useful varieties for succession are Vermillon Brilliant (the finest of all scarlet varieties), Canary Bird, Cottage Maid, Joost Van Vondel, Keizers Kroon, and Wouwerman (a good late variety). Amongst doubles procure Tournesol, scarlet and yellow and the yellow form; La Candeur, white; Rex Rubrorum, scarlet; two of the best late varieties. These may be had until June by potting late in October, and keeping them in a northern position afterwards. Both are good for cutting, and may be sent any distance during the month of May.

Polyanthus Narcissi.—For early flowering Paper-white and Double Roman should be grown five or six bulbs in 6-inch pots, the size we have found most suitable for these bulbs. Gloriosus and States General are two cheap and very early kinds. To these may be added Grand Monarque, Grand Soleil d'Or, and Newton. If the last of Grand Monarque are potted the last week in October and kept outside they will be found useful in the conservatory when all spring-flowering bulbs are over, or for cutting with the double late Tulips that have been named.

Scilla siberica.—Where these are appreciated in pots place the bulbs thickly together in 4½-inch pots at once. Cover the bulbs with 1 inch of soil, and plunge them the same as advised for Hyacinths and Tulips.

NOTES ON BEES.

BEES THROWN OUT OF A HIVE.

SAMPLES of bees have been received from "F. H. M.," who wishes to know the cause of so many bees being thrown out of a hive at this time of year. It is difficult to determine the cause without seeing the hive or hearing full particulars respecting the situation and surroundings. Some of the bees on dissection contain a milky-looking liquid, and have an odour not unlike "pot ale," the refuse from a distillery. Are the bees near one, or have they access to dregs of ale or porter? They do not seem diseased in the proper sense of the term. They are not all alike. Some of them are young bees, and it is a common occurrence at this season for stocks to draw much of their brood unless prevented by liberal feeding, which is in some cases neither prudent nor advisable to do. We shall be glad to hear full particulars.

BEES SWARMING.

The cause of this is hardly worth consideration, as the subject has so often been explained in these pages. But it appears some bee-keepers do not thoroughly understand it. Therefore a few words of explanation, if they should be a repetition, may not be out of place. Some bee-keepers, one in particular, writes, "Keep the variety that is not inclined to swarm!" I have yet to see this wonderful variety of bee. Others write of certain ways and means of preventing swarming, which is simply the original methods, and not "a new system." I observe some American writers affirm the cause of swarming to be an excess of "indoors" or young bees, and run into the same old error that many have done before, of fixing the life of the honey bee at as many days as it should have been weeks. Another plan is that of "Felix," which I am ignorant of as yet, but await patiently the instructions how to prevent swarming by "skilful management." My own opinion in the interim will neither interfere with his information nor disturb him in the least, and for the benefit of bee-keepers I will explain the causes of swarming, and how in certain cases it can be prevented; but without such manipulations as I describe it would be impossible.

SWARMING FROM SMALL HIVES.

It is a well known fact that bees in small hives will increase by swarming naturally, much more quickly than where full sized hives are kept, but the latter are not exempt. In our early bee life, when using hives larger than those generally recommended, but smaller than we now use, it was customary to have ekes, or at times a super, to prevent swarming. I soon discovered that this, in addition to having an excess of drone comb built, was not a successful method, especially where a queen of more than one year old

existed. Had I been plodding on in the old rut with straw hives, or even wooden boxes with solid crowns, I could not have improved the condition of things, but using then divisional hives, much like those I now use, I prevented drone comb being built in excess by preserving the barred boxes full of comb from the previous year to eke with, thereby getting stronger hives with less drone comb. In a year or two after I hit upon my frame hive contemporaneously with continental bee-keepers without having the slightest knowledge of what they were doing. This led me on to have a better knowledge of the cause and effect of certain things in connection with the honey bee. I saw at once that a young and fertile queen did not influence the bees to swarm as in the cases where an aged one was regnant, unless when the bees became crowded in a too small hive, but I also saw that in cases, whether the queen was young or old, if the hive was extra large with a teeming population that hive had an inclination to swarm. Then if the weather was warm and favourable for bees to work and gather much pollen and a little honey, swarming was more certain than when honey was abundantly carried into the hive, the bees evidently more bent on filling up every available space with honey than on the increase of the colony; hence the queen, naturally desiring rest, was left undisturbed, and the weather breaking after the honey glut the bees became contented and swarming for the time ceased. Owing to this perhaps almost, if not wholly, exhausted queen, a fugitive swarm in spring was almost sure to issue, leaving nothing but combs behind, or an untimely one further on, leaving behind it combs but sparsely filled with brood. I have dissected many queens of the so-called "hungry swarms," and not one of them had spermatheca to fertilise any great number of eggs, while some of them were completely exhausted as well as the ovaries. I predicted last autumn that there would in all probability be much disappointment this summer from the above causes owing to so few young queens having mated, causing old ones to be kept, and it has turned out as I warned.

Even lately some bee-keepers were bent on keeping queens that have done well the past summer, but after I remonstrated with them on the folly of doing so imported queens were obtained, and the old queens sent me for examination. All of them were exhausted, which not only showed on dissection, but the combs after heavy feeding did not contain a single egg.

The foregoing shows plainly how swarming is brought about in ordinary bee-keeping. If a queen is seeking for repose or exhausted at a time the bees are actively at work, whether there is plenty of empty combs or not, royal cells are brought forward in greater or less numbers, which has something to do with the number of after swarms that will issue, depending on the breed in this respect only, but has nothing whatever to do with the issuing of the prime swarm. It is safe to say that the conditions required to bring about swarming are almost identical, whether the hive be large or small, unless in the case of a very fertile queen, when an eke has been given.

HOW TO PREVENT IT.

There is but one way, and that is to keep the hive in a normal state for working. Overhaul the combs at a suspected time, and note the appearance and attitude of the queen, and of the bees towards her, as well as that of the number of eggs laid, for it is well to state that shortly before the exhaustion of a queen she lays an extra number of eggs. If no royal cells are being raised the hive may be allowed to go on for a few days longer, but in most cases after a queen has laid greatly for nearly a year she should be marked as suspected. Before attempting to depose a seemingly fertile queen have in readiness a fertilised one to take her place. Take every precaution necessary for her welfare, cageing her at least twenty-four hours amongst or over the bees after the colony show signs that they miss their previous one, with a further examination to find if queen cells are being brought forward before letting her free. The young queen on being set free amongst the fraternised bees will shortly begin to lay, and that greater than at

any time during her whole after-life. It is therefore absolutely necessary to give full scope to her laying powers by the introduction of empty combs in lieu of full honey ones, or an additional breeding box. The daily hatching of many young bees will give her full scope, and there will be no inclination of the bees to swarm again from four to six weeks after, which by that time in many cases will not take place. The above is the only method by which swarming can be prevented.—A LANARKSHIRE BEE-KEEPER.

BEEES IN STRAW SKEPS—TAKING HONEY.

I BOUGHT a swarm of bees this spring. They have swarmed twice, first about middle of June, second about fortnight later; they are all in straw skeps. I intend taking the honey from the parent hive. Could you inform me the best time for such operations, also how to get the bees into another hive, and what kind would you recommend? Which is the best manner to feed bees in skeps, and what is the best mixture? How would you manage to get the honey from the combs in a clean state?—A NOVICE.

[The best time to take the honey from straw skeps is in three weeks after the first swarm issues, because at that time, as a rule, little brood is in the combs, but even now there will be comparatively little. The bees require to be driven by the usual method, and then they can be re-run into whichever hive you choose, or the bees may be shaken on to a cloth and the hive placed directly over them, avoiding crushing any by placing two sticks beneath the hive.

The best hive for every purpose is the Lanarkshire storifying hive, or if honey is not for sale the Stewarton. Any novice can make the former, and the latter can be had from Messrs. G. Neighbour & Sons, 149, Regent Street, London. The mode of making the first named was fully described in previous numbers of this Journal. It will be necessary to have the frames fitted with foundation. A tin fountain with a wooden float (thin) is the best feeder for straw hives, but in case the bees do not clean out the syrup thoroughly remove it every morning. May be had from some dealer. The best feed is the best sugar to its equal weight in water dissolved over a slow fire, stirring the while till dissolved, boiling about one minute.

To take the honey from combs in a clean state where it is much thickened nothing equals the Lanarkshire honey presser. Select the combs to be pressed, setting aside the portions containing pollen, then cut into strips size of perforated cylinder, ram down, and when full put under the screw. The portions containing pollen should be laid on their flat and pressed gently. After the honey is pressed it is necessary to strain through muslin. My strainers are a series of sieves, the last being a tapered and pointed muslin net bag depending on the kind of honey. The so called "Rait presser" originated from this one, but is not adapted for taking large quantities of honey. Moreover, the hands are always soiled with honey, whereas with the Lanarkshire one no such thing occurs. As you will also be wishing to extract the wax no better instrument can be had for this purpose than the Lanarkshire presser. A wide cylinder of perforated tin lined with cheesecloth is all that is necessary. Put the wax into a large melting pot, melt, but not to boil the combs, then ladle the wax into the cheesecloth (bag or loose), close the opening and press. With such an instrument several combs of wax could be melted daily, and not a speck of wax out of place.—A LANARKSHIRE BEE-KEEPER.]

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Address (W. S.).—You have inadvertently omitted your name and address, which we shall be glad to be favoured with; not for publication.

Grapes (J. C. and Cambrian).—Letters arriving on Wednesday morning cannot be satisfactorily answered in the current issue, which is then far advanced for the press.

Wasp-killing Mixture (R. R.).—Possibly there may have been more than one preparation advertised, and we cannot tell to what you particularly refer. Messrs. Barelay & Sons, Farringdon Street, have advertised a preparation called "Death to Wasps." If that is what you mean, we think it can be obtained through chemists.

Caterpillars and Fruit Trees (P. M.).—For the purpose of preventing the wingless female winter moths (cheimatobia) ascending the stems of trees, stout paper is tied round them, and this is thickly smeared with equal parts of Stockholm tar and cart grease. Some persons apply it to the bark, but we do not recommend the plan. Miss Ormerod suggests that haybands mixed in tar and oil, then laid round the stems of the trees, not quite touching them, might answer. Mr. S. T. Wright, Glewston Court, where fruit trees are extensively and admirably grown, did not find the glutinous barriers effectual, but we do not know at what period of the year he provided them. The moths emerge towards the end of October, and continue ascending the trees at night for several weeks.

Contents of Fruit Sieves (A. J. N.).—Market measures vary in different districts. We presume you desire to know the nature of those in Covent Garden. They are as follow:—A half sieve contains 3½ imperial gallons. It averages 12½ inches in diameter and 6 inches in depth. A sieve contains 7 imperial gallons. Diameter 15 inches, depth 8 inches. A sieve of Peas is equal to 1 bushel; a sieve of Currants 20 quarts. A bushel sieve contains 10½ imperial gallons. Diameter at top 17½ inches, at bottom 17 inches; depth 11½ inches. A bushel basket ought, when heaped, to contain an imperial bushel. Diameter at bottom 10 inches, at top 14½ inches; depth 17 inches. Walnuts, Nuts, Apples, and Potatoes are sold by this measure. A bushel of the last-named cleansed weighs 56 lbs., but 4 lbs. additional are allowed if they are not washed. A junk contains two-thirds of a bushel.

Pruning Vines (Triceps).—We should not like to grow a Vine for fourteen or fifteen years without fruiting, but as yours produced fruit for the first time last year there appears a disposition to improve. We suspect the Vine is in an enfeebled state, and copious supplies of liquid manure might be of great service. If the Vine is well supported at the roots it will push good growths after the rod is cut back as you propose, and if these are trained 18 inches apart grow strongly, reach the top of the house, and ripen well, they will bear much better Grapes than can be had from weak closely spurred laterals. If you had sent us a sample of the young wood we should be in a better position to advise you on the subject. Assuming you remove the rod, we should cut back the laterals to the best buds where the wood is firm, regardless of their distance from the main rods from which the laterals proceed. Some soil dug from the roots, adding fresh with wood ashes, surfacing with rich manure might induce the production of fresh roots for imbibing nutriment in the form of liquid manure.

Transplanting Ferns (N. J.).—There is no better time for transplanting Ferns than just as young fronds show signs of uncurling in the spring. The ground should be well broken up some time previously, as they will not thrive on a hard dry subsoil, and vegetable matter, such as may be gathered in plantations, should be liberally mixed in the soil. The common Bracken is one of the worst to transplant, because compact, well-rooted clumps, are the worst to secure. You must therefore exercise care in selection. Dig the roots up in large squares, plant firmly, water well, and mulch thickly with decayed leaves to prevent the escape of moisture from the soil. The plots you desire to establish in the park should be protected from cattle, for though the animals may not eat the fronds, they would be certain to trample on the ground, and in that way render your work futile. During some seasons the growth of transplanted Brake Ferns is much better than in others, and if you fail in the first attempt, try again. We have seen many failures and not a few successes in transplanting this Fern.

Quick-growing Wall Plant (J. M.).—To your query, "What is the most effectual plant for covering the walls of a large stone house with green stuff in the shortest possible time?" our reply is, We do not remember any plant more likely to answer than the Virginian Creeper, *Ampelopsis hederacea*, but it rarely affords "green stuff" during the summer. The rapidity of its growth also depends on the character of the soil; the better and deeper this is, the sooner are walls covered. We know a brick wall facing the south that is now covered to a height of 15 feet with growths of the present year, and we inserted cuttings from a plant in July, the growths from these being now 6 feet high. This particular form clings fairly well to brick walls, but might not do so on a rough stone surface, but would probably require the support of nails and shreds. The small clinging *A. Veitchii* will adhere to any wall, and produces a more pleasing surface of "green stuff" than the other, but not quite so quickly. If you require an evergreen, plant a strong growing Ivy in rich soil, mulch with manure, and give water as is required in the summer. If any of our readers can suggest plants more likely to answer your requirements they are quite at liberty to do so.

Celery Fly—Tomatoes (W. E. B.).—The Celery leaves contain small maggots, which hatch from the eggs which a small fly (*Tephritis*) deposits in them, puncturing the surface for the purpose. When the maggots are numerous they eat out the substance of the leaves and often ruin the crops. When the first blister is seen gardeners dust the plants with soot frequently, and this deters the flies from visiting them,

but soot will not destroy the maggots in the leaves. You had better pick off all the blistered parts and burn or bury them deeply, then dust with soot. Some gardeners save their crops by syringing the plants with petroleum, such as is burned in lamps, adding a small wineglassful or less to a gallon of water and mixing by violent agitation, which is continued during the time of application in the form of spray through a syringe. If the agitation is incomplete the oil floats on the water. The mixture should only be applied in the evening, as if the sun shines brightly on the leaves before the oil evaporates they are apt to be scorched. Well mixed and rightly used, we have known Celery kept clear of the enemy, and the maggots destroyed in the leaves. The nozzle of the syringe cannot be too finely perforated for the application. Try the effect of the mixture, applying it as best you can on half a dozen plants before using it extensively. The crimson Tomato you send is Dedham Favourite. It was distributed by Messrs. Carter & Co., and is a favourite with many persons besides yourself. The scars on the fruits of the other variety are not infrequent, and are the result of the adherence and decay of the stamens.

Tuberose Culture (J. S.).—The following simple method has been described by a very successful cultivator. Procure sound well-ripened bulbs as soon as you see them advertised. If in quantity divide them into two or three batches for succession. Pot the first at once, either three bulbs in a 32-sized pot, or one good bulb in a 48-pot. In either case use a rich loamy soil, or if the loam is poor add one-third of well-decayed manure that will pass through a quarter-inch sieve, and a little sand. Pot rather firmly, afterwards place them in a cold frame, or under the stage of a greenhouse where there is little or no drip from plants above, and cover them with cocoa-nut fibre refuse, fine coal ashes, or some other material that will run between the pots. This will keep the soil sufficiently moist for rooting to commence, which will begin in a fortnight. As they advance take them out, and for a few days place them in a position where they at first have but a moderate light, such as under the stage of a plant house. It will be seen that the young growth will gradually assume a natural colour, when the plants may have the full light and heat of an intermediate house. A stove heat is more than they need, and to have them in flower quickly a cool greenhouse is not sufficient. After making a little foliage the flower spikes begin to appear, and as they grow to from 2 to 4 feet in height and are very slender, a stake must be placed to each. Each spike if good will produce two dozen blooms in succession, pure white with a most delicious fragrance. When in bloom they are conspicuous if placed in the conservatory with the spike of flowers arising just above other plants, but they would be principally required for cutting. The perfume is strong, therefore for room or any part of house decoration too many must not be employed at one time. During growth the plants are subject to the attacks of green and black aphides, which infest the spikes of flowers. Liquid manure given twice a week will be found to benefit the plants, and by potting in succession they may be had in flower during the greatest part of the year. They are among the most useful for cutting for bouquets, wreaths, and buttonholes, as they are sweet-scented, pretty, and last a long time.

Diseased Tomatoes (S. D. C.).—The disease with which the examples sent are so seriously infested is, if not identical with, substantially the same as the Potato disease. It is caused by a fungus (*Peronospora*), and is induced by succulent growth caused by errors in watering and ventilation. When these errors occur in unheated houses the attack is often virulent, as in your case, and most difficult, if not impossible, to check. A high temperature and dry breezy atmosphere should be maintained on the first appearance of the disease. All such fruits and leaves as you have sent should be cut off and burned, the house kept as dry as possible, the more slightly affected parts well sulphured. A solution of sulphate of iron (green vitriol) is said to be an enemy of the disease, but it must be used experimentally, trying its effects on a plant or two at the rate of an ounce to 20 gallons of water, increasing or reducing the strength according to the results of the application. The leaves before us are much too soft and destitute of tissue, hence in a condition peculiarly liable to injury and by fungoid attacks. Mr. Iggulden in his useful work on Tomatoes has the following remarks on the *Peronospora* attacking the plants:—"Under glass, and especially in well-heated houses, it is possible to either prevent an outbreak of the Potato disease, or, at any rate, to materially check its progress. After repeated trials and close observation I have arrived at the conclusion that many failures are due to haphazard ventilation. A moist atmosphere is most favourable to the outbreak and spread of the disease, and it is my belief the spores are generally admitted through the front lights. In windy, sunless, rainy weather these ought, therefore, to be kept nearly or quite closed, the top lights being opened, and if possible sufficient fire heat afforded to maintain a buoyant atmosphere. Nor should a current of moist and, it may be, disease-laden air be allowed to pass through pits and frames when these are planted with Tomatoes. In clear warm weather the lights may either be drawn off or blocked up in the centre, but when disease is in the air the lights ought to be pushed down from the back only. Every affected leaf or a portion of a leaf should be removed directly it is observed and burnt, and occasionally it may be necessary to cut a portion of the stem clean out." You say you have only watered the plants "moderately" and "given plenty of ventilation." It is possible, as you will perceive by the above citation, to admit air too freely under certain atmospheric conditions; and your idea of "moderate" supplies may differ from ours. For instance, if you have given a little water daily or even thrice a week, keeping the

surface of the soil damp, and consequently the atmosphere, moderation in quantity given in that manner would be much more likely to bring about the disease than thrice the aggregate quantity of water given once a fortnight. We know by the state of the leaves that there has been too much moisture in the air, if not in the soil. You do not say whether the plants are planted out or not; if they are we should not allow a drop of water in the house for at least three weeks, no matter how dry the weather may be.

Double Sunflowers (*W. B. H.*).—The flowers sent in green grass have arrived as fresh as when cut from the plants.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*W. W.*).—1, *Rudbeckia hirta*; 2, *Campanula Trachelium*; 3, *Echinops ruthenicus*; 4, *Aster laevis*. (*W.*).—1, *Cassia corymbosa*; 2, *Polygonum cuspidatum*. (*Hugh, Paris*).—1, *Begonia semperflorens*; 2, *Adiantum pubescens*; 3, *Panicum variegatum*; 4, *Gymnogramma chrysophylla*; 5, *Spiraea aruncus variegata*.

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (*R. C. A.*).—The Plum you have as *Victoria* is probably Autumn Compôte. The red Apple is a good specimen of the Worcester Pearmain, the other is the Burr Knot. We shall be glad to hear what you have to say about it and its culture in your district. The other Plum was smashed between the Apples, and the juice rendered the writing accompanying it quite unreadable. (*T. W.*).—1, Yorkshire Greening; 2, Bess Pool; 3, Domino; 4, Trumpington; 5, Caroline; 6, Summer Crasanne. (*J. Drew*).—Not known in their unripe state. (*G. R. J.*).—1, Northern Greening; 2, Lady Apple; 3, not known; 4, Greenup's Pippin; 5, Duchess of Oldenburg; 6, Cellini. (*John Warner*).—Orleans. (*H. W.*).—1, Devonshire Quarrenden; 2, not known; 3, Red Winter Calville; 4, Hoary Morning; 5, Blenheim Pippin; 6, Wormsley Pippin.

LANDLORDS' FARMING.

INDULGENCE of fanciful extravagance in farm buildings is a thing of the past. Strength, durability, and practical utility are the chief points to keep in view in the restoration of homesteads. During the last few years we have had to repair a lot of neglected homesteads, which originally were none of them really durable. Stud and plaster on underpinning of clay or bricks, clay walls, thatched roofs, or pantiles laid so carelessly as to admit snow or rain whenever accompanied by wind; open cattle sheds, so narrow as to afford little shelter in a storm; roof timbers, so slight as to yield to the weight of the covering materials, were among the most serious faults, most of which betokened ignorant or careless supervision, and contract work badly done.

As an example we may take one of the homesteads which have been set in order during the present year. This is a farm of 130 acres, the buildings of which were badly constructed, inconvenient, and several of them were quite unfit for the required purpose. The horse and cattle yards had clay walls, with narrow open sheds, supported by the walls on one side, and wooden posts let into the ground on the other. Both supports were failing—the walls being cracked and bulging outwards, and the posts being decayed at the bottom; one roof had fallen in, and the others were unsafe. Repairs were evidently out of the question; the walls were replaced by others of 9-inch brickwork, and new sheds 18 feet wide were made with roofs of stout deal timbers covered with corrugated tiles, the back plate on the wall, the front plate on oak posts with cast-iron bases sunk in the ground, the roof being tied to the beams, plate, and posts by iron dogs and angles. The roofs had a rise of 6 feet in centre, and the scantling of timber for it was—wall plate, 6 inches by 6 inches; front plate, 7 inches by 3 inches; beams, 5 inches by 6 inches; principal rafters, 5 inches

by 2½ inches; single rafters, 5 inches by 1½ inch; collars, 1½ inch by 9 inches; ridge, 9 inches by 1½ inch; purlines, 5 inches by 2½ inches; oak posts, 7 inches by 6 inches, and 8 feet long. These particulars are given because the sheds prove very commodious and comfortable, and also because we have seen so many badly designed sheds. Given a wall 10 feet high, a span roof with a width of 18 feet on front, oak posts set in iron bases, and we have a building which can hardly be surpassed either for open shedding or for conversion into stables, loose boxes, or cowhouses, which is easily done with partitions and front of studding and weather boarding upon 2 feet of 9-inch brickwork. No woodwork must be in contact with the ground, but must rest upon hard imperishable materials.

The most serious matter in the restoration of the homestead was the rebuilding of a granary, piggery, fowl house, swill and storehouses. These were all under one roof—a thatched roof with walls of stud and plaster—the entire building being in such a state of decay that any attempt at repairs would have been an absolute waste of money. In this old building the pigsties were a series of small pens on each side of a narrow passage under the granary with no open courts. There was hardly sufficient space for a full grown sow to turn round in any of them, and many a suckling must have been smothered by the sow lying upon it. Now, we have frequently built granaries over piggeries, but care has been taken to have each pen about 8 feet square with an open court in front. Had it been possible to repair the old building the pigsties would have been enlarged and open courts added. It is undoubtedly owing to the confinement of swine in such unsuitable places, and the filthy condition in which they are kept, that swine fever is so prevalent.

Our best arrangement for pigs is enough pens with open courts for sows and sucklings, each pen having an inner door opening into a passage with a door at one end. When the pigs leave the sows they are all turned into a large open shed with a yard in front for feeding; plenty of fresh litter is used regularly in shed and yard, and the pigs are always healthy there.

The dilapidations of the homestead to which reference has been made afford proof of the absolute necessity for prompt attention to repairs; a moderate annual outlay is always preferable to heavy expenditure at longer intervals. To have farms falling in hand now is bad enough, but the burden becomes doubly heavy when to reclaiming farmed out land is added the extensive repairs of buildings. Nor can such outlay be avoided, for if a farm is to be re-let the buildings must be sound, and the land in sound condition too. The only course to adopt is to see that the repairs are in keeping with the style of the buildings, to make such improvements as the substitution of weather boarding for plaster, of bricks for clay, and of tiles, slates, or corrugated iron for thatch. A specification of what is required should be drawn up, copies sent to two or three tradesmen, who may be invited to tender for the work, and subsequently it rests with landlord or his agent to see that the work and materials are satisfactory. We have recently been able to effect a saving of some £70 to the estate by so acting, and though the lowest tenders were accepted the workmanship is highly satisfactory. One word more. Avoid thatch in all new buildings; it may look picturesque, but it wears out quickly, and no tenant upon a small farm likes to have to find the straw.

(To be continued.)

WORK ON THE HOME FARM.

Corn harvest is ended, and most of the corn has been stacked in much better condition than was possible last year. Some of the best samples of Barley have realised as much as 39s. per quarter, but Wheat has not risen above 33s., and we know of one inferior sample being sold for 24s. The higher price affords no inducement to thresh Wheat now, and apart from what is required for seed it will probably be left in stack till after the Barley threshing, unless from any cause there should be a slight advance in price. With such fine weather much Wheat will be sown during the present month, care will be taken to select the best seed of the best sorts, and if necessary it will be screened two or three times upon the principle that like produces like, and if we sow fine seed we may hope to have fine corn next harvest. Let it not be forgotten, too, that our practice must be well balanced, and if we would have as full a measure of success as possible nothing must be wanting in the

soil—drainage, porosity, fertility, cleanliness—all these are indispensable factors to success. If we grow Wheat at all now it must be well done, or it will lead to failure. We happen to have seen both the samples we have mentioned, and the difference in them of 9s. per quarter was only fair, and was a true indication of the way in which the two farms where the Wheat was grown are managed. The superior sample was a legitimate result of sound practice into which sheep folding enters largely; the other was an outcome of general low cultivation, and the crop will not pay expenses. The grower has twice failed in business, yet fails to apply the lessons of adversity, nor is he one to whom advice can be offered; certainly in the inevitable ruin which he appears to court he will have no real claim to pity.

The weather is most favourable for cleaning the land. Broadshares, light and heavy harrows are kept briskly at work, and horse-rakes have been found very useful to get the weeds together for burning. The surface is sufficiently soft to admit of a free use of broadshares with which about an inch deep of the entire surface is pared, the rubbish then being worked out with harrows. After a drought this cannot be done, ploughs and cultivators having to be used, and then the weeds cannot be got out so easily or so thoroughly. Such an autumn as the present is certainly a golden opportunity, which if turned to full account may lead to a great saving of labour next spring and summer. If there is couch grass in the land the cultivators may be useful now, but if there are only patches of it in different parts of a field it should be got out with steel forks before the broadshare passes, even if it is necessary to keep on an extra man or two for the work.

SEED WHEAT.—Messrs. Webb & Sons have sent us some Wheat ears which are remarkable examples of skilful cultivation, and which afford tangible proof of the importance of careful selection. Among them Kinver Giant well maintains its position as a veritable giant among Wheats, but it has no mean rival in Rough Chaff White, the ears of which are almost as large, though quite distinct in appearance from it. Webb's Challenge and their selected Golden Drop have also fine long bold ears. Challenge has handsome plump very white grains; its yield is said to be enormous, and it is also specially recommended as suitable for all soils, and as being equally adapted for either spring or winter planting. It is by no means a new kind, having been introduced by the firm in 1874. Golden Drop is too well known to need one word of commendation from us. We know, however, that very inferior samples are frequently on offer at market under that name, and we certainly advise those who care for this old miller's favourite to procure a supply of so fine a selection, and to try if they cannot produce a crop up to Messrs. Webb's standard. We must admit that among these remarkable specimens the ears of Square Head commend themselves most of all to our approval. The short, thick, and very compact ears as usual form an admirable crown to the exceptionally stout straw which hardly ever becomes lodged. The grain is large and plump, and we know from long experience that high quality in combination with an abundant yield is always present in samples of this general favourite. No doubt the admirable manner in which the ears are kept erect by the sturdy straw tends to promote high quality in the grain. The point is important, and we may mention a sample of pure Square Head of the harvest of 1888 which weighed 65 lbs. per bushel, and which realised 7s. per quarter more than ordinary samples. The ears of Mountain White, though less attractive than others, are not to be passed by lightly. We have seen this new Wheat in cultivation, and believe it has a great future, for it has wonderfully large grain twice the size of most Wheat. The straw is so stout as to be almost reed-like in proportion, yet it is so slender at the top that the heavy ears droop as they ripen, but the straw though very long passes with impunity through every storm, and is never beaten down. We congratulate Messrs. Webb upon the success of their selections. It is a work of national importance rising far beyond the level of a mere trade speculation, for if British farmers are to hold their own in competition with the markets of the world they must strive for the best possible combination of quantity and quality in their farm produce.

REMARKS.

8th.—Fine and occasionally bright.
9th.—Cloudy till 10.30, then fine and frequently bright.
10th.—Bright and warm, but hazy at times.
11th.—Warm and generally bright, but cloudy at times in afternoon.
12th.—Bright and warm.
13th.—Bright and pleasant.
14th.—Cooler, but fine and pleasant.

A very fine warm week, in fact, with only three exceptions, the warmest week this year, and also a fine one—G. J. SYMONS.

VEGETABLES.

As time rolls on more and more attention appears to be given to the particular aspect of gardening that is represented by food-producing crops. But while this is so it is satisfactory to know that the ornamental and pleasure-giving parts are not correspondingly neglected. With commercial prosperity and a growing disposition among the greater number to engage in home pleasures and occupations the advancement of the useful and the decorative branches will be contemporaneous. "Horticulture can never flourish in any country where the pleasures of life are not sought for at home." Thus wrote the founder of this Journal sixty years ago. Those words represent the truth and go to the root of the whole matter of prosperity in gardening. Those "home pleasures" which it is so desirable to promote may take various forms. The cultivation of plants and flowers may be indulged in by some who are made happier by the association, but, either connected with them or independent of them, fruit and vegetable production is an occupation which affords delight equally to many, and the number is undoubtedly increasing.

Vegetables are now under more immediate consideration, and these have been more extensively represented during recent years at most of the important exhibitions of garden produce than was the case in past times, and with scarcely an exception quality has advanced with quantity. New varieties have superseded the old except in a few instances, and greater care has been exercised by a greater number in producing them in the highest condition. Possibly a tendency has been apparent to grow certain vegetables to an abnormal size; but as any approach to coarseness meets with the disapproval of the best judges there is not much fear that bulk will, except by accident, be honoured at the expense of quality. It is not easy to err perhaps in growing some vegetables too large. Asparagus, for instance; and small ill-fed Peas are inferior to some of the larger and better supported; but unwieldiness in size of the majority of vegetables, root as well as green crops, represents waste both in the form of labour and manure, while grossly overgrown examples are defective both in flavour and nutritious properties.

The cultivation of vegetables with the object of maintaining a supply of the different kinds as they can be had for use, and in the best condition in which they can be produced, as estimated by their appreciation at table, is an engagement worthy of the best efforts of the best men in the gardening ranks. As is well known the most competent of these pay particular attention to the culinary department, and it is very rare indeed that those who succeed there fail generally. Competency in vegetable culture is one of the most substantial of the gardener's acquisitions, and the possession of the qualifications give to a gardener a distinct advantage in his calling. This is a fact, and it should be recognised by young men especially who are hoping to attain to good positions in life. If they make themselves masters of the art of vegetable production, the knowledge they have gained will be available for other purposes, and they will not experience many cultural difficulties which they cannot surmount in other departments so far as means permit.

Having in view the great importance of a full and high class vegetable supply, also the desirability of judging by comparison of the claims to favour of the different varieties, recognising also the desirability of acquiring information pertaining to the whole

subject, the Council of the Royal Horticultural Society placed themselves at the head of a great effort to bring garden vegetables more prominently forward, and to assign them, in fact, a front rank position in the gardening world. The result of the decision may be seen at Chiswick, for these lines will reach many who are interested before the conference closes, and the gathering is a great success. Entries are received from various parts of the country of the best examples of culture from England, Ireland, Scotland, and Wales, with samples from France. An idea of the extent of the aggregate contributions may be gathered from the provision made for their reception. The famous vinery, 180 feet long, is furnished with four lengths of tabling, and the same number of tables are similarly arranged in a tent 190 feet long, or allowing for space for the conference, the reading of papers, and discussion, over 1000 feet in length of tables are required for the selected produce as invited by the Committee.

As a non-competitive display it is an extraordinary exhibition, and it is doubtful if any other horticultural society in the world could obtain such a show without offering a single prize; all the exhibitors and judges performing their tasks without reward beyond the satisfaction derived from assisting in a useful work. This fact alone must be most encouraging to the Council and officials of the Royal Horticultural Society, as it proves conclusively that this body still possesses considerable power over the gardening community of this country, and its influence exercised in right directions is productive of much good. It also redounds greatly to the credit of horticulturists in such a prize-giving and prize-winning age as this that so many are ready to give their services for the general rather than special or individual benefit. As M. Henry Vilmorin rightly remarked at the dinner held on Tuesday evening, the Chiswick exhibition reflects as much honour on those who have provided it as upon the Council of the Society who originated the idea and the Committee that elaborated and carried it into execution.

Regarded simply in the same way as a competitive show of vegetables, that at Chiswick might not be considered satisfactory except in a few classes like those for Onions and Carrots. But the chief object has been to show as many distinct varieties, types, or strains as possible, each sufficiently true to indicate its respective characters, and to enable the public to form some idea of the best in each class. Much assistance has necessarily been rendered in this direction by seedsmen who in the majority of cases show praiseworthy samples of their specialties, and in the few instances where there is a falling off in quality it is mainly due to the date being a little too early for the particular sorts. This is seen in the Brussels Sprouts class more especially, but it is noticeable also in the Savoys and some other classes. Amply sufficient is staged in all classes to afford the Committees due opportunity of making fair comparative selections, and to these we must look for the practical outcome of the Vegetable Show. It is true that a few of the leading seedsmen have not contributed to the display, but in private growers' collections many of their varieties are admirably represented, so that it will not materially affect the decisions of the selecting Committees.

Awaiting these selections we have been unable to give more than a summary review of the classes and exhibits, pointing out those varieties which are shown in the best condition, and naming the seedsmen or gardeners who contribute most largely to this instructive Exhibition. The different districts and soils from which the produce is sent should also indicate in an interesting manner, when all the particulars are available, the behaviour of certain varieties under widely different circumstances—a good test of their characters.

Novelties are not numerous, and there are no special departures from ordinary types to be chronicled, but all who visit Chiswick must agree that it is the most representative and important display of vegetables ever brought together in this country.

The following are the Committees for examination and selection in the respective classes, though some of the members were unable to attend, and others were substituted.

A. Green Vegetables.—W. Nutting, J. Muir, J. Walker.

B. Fruits and Pulse.—P. Barr, W. Iggulden, J. Burnett, R. W. Ker.

C. 1, Potatoes.—C. Fidler, G. T. Miles, J. Smith, P. McKinlay.

C. 2, Tubers, Bulbs, &c.—A. Watkins, C. J. Waite, J. Willard, M. Dunn.

D. Tap roots.—A. Moss, F. Ross, G. Breese.

E. and F.—Saladings and Miscellaneous.—W. Poupart, W. Wildsmith, E. Molyneux.

Referees.—A. W. Sutton, C. H. Sharman, J. Harrison, T. Laxton, W. Ingram, C. Silverlock, J. Douglas. Chairman, Dr. Hogg, F.L.S.

The members of the Special Committee act as stewards on the occasion.

MANDEVILLA SUAVEOLENS.

LARGE, pure white, sweet-scented flowers always secure appreciation. They are valued more particularly when forthcoming at a time of comparative scarcity, when other flowers of the desired character are not in season. Of this description is *Mandevilla suaveolens*. It flowers in late summer and autumn, producing its pearly white deliciously scented flowers profusely and successively over a lengthened period. It is, indeed, a very handsome greenhouse climber, or rather twiner; native of Buenos Ayres. Flowers sub-corymbose or in a simple raceme; corolla salver shaped, with naked throat and tube, pure white, large, very fragrant, and profusely produced; leaves opposite, oblong, dark green. It is of free and rapid growth, vigorous shoots extending over a large space—20 to 30 or more feet in a season under favourable circumstances, which are rarely accorded, consequently this very desirable plant is seldom seen in a flourishing condition. We may occasionally see a plant thriving fairly well under pot treatment, but such are exceptions to the general rule. In brief, my experience accords with that given in Johnson's "Gardeners' Dictionary"—viz., "Does little good as a pot plant, but is splendid when placed out and allowed room in a greenhouse or conservatory, where fine climbers are prized." I have tried to grow and flower it in pots but with little success, as the plants, whether from seed or cuttings, afforded only a few flowers, and after a time were the most unsatisfactory of any plant I have ever attempted to grow, for the foliage invariably became a prey to red spider, or was irretrievably injured by the steps taken to expel the pests. The plants grew freely enough for a time, advancing promisingly up to the flowering stage, when they seemed to lack force. Feeding only accelerated the collapse of the plants. I have recollection of a well-flowered plant grown in a pot and trained to the roof on an intermediate house at the nurseries of Messrs. Backhouse, York, some thirty years ago, and it was the only well-flowered plant of it I have seen growing in a pot. Others I have seen before and since were failures, and clearly through ill-health. Seedling and cutting plants alike grew freely enough for a time, but only to sicken and die. Why? The only analogies that occur to me are in *Luculia gratissima* and *Rogiera gratissima*, both of which are miserable objects grown in pots compared with the magnificent heads of flowers produced when planted out.

Whatever causes the difference is beyond "ken," but there is this in relation to *Mandevilla suaveolens* that a plant was never seen flourishing for any length of time in the compost advised by the authorities. All to which I have access recommend a compost of "good peat and turfy loam in equal parts, to which may be added plenty of silver sand." All I have seen succeeding were growing in soil of which peat formed no component; in fact, a light porous and non-phosphatic soil seems fatal to the health, a sturdy growth and floriferous habit. In available potash salts, phosphoric acid, and soluble silica lies the secret of success. Potash salts and phosphoric acid are rarely found in peat, and the loam, if it be light, often does not contain a measurable quantity of either. Lime is not largely present in peat or turfy loam. This, however, may not be a necessity, yet strong loams contain phosphatic matter much more abundantly than peat and turfy loam. The plants may find sufficient phosphatic and potassic matter in the leaf soil or well-decayed manure, which usually occur in compost of peat and loam, but those being speedily exhausted the plants collapse.

Light soil, no matter how rich, will not keep *Mandevilla suaveolens* healthy and floriferous. It requires a strong loam, and preferably off chalk. Nothing is better than the top 2 or 3 inches of a pasture taken off with its turf. Such requires no admixture, merely needing to be chopped up and put 24 inches deep over a foot

depth of efficient drainage, secured with a 3-inch thickness of old mortar rubbish. A border 2 feet wide is ample. The plant will grow and have stems, many issuing from the base, and nothing will prevent its flowering every year from August onwards to late autumn, only train the growths 6 to 9 inches from the glass unshaded. We have, however, a little shade of whitening this year, and the plants are flowering as freely as before, but the clusters are not so large as where the growth is better solidified.

The growths require to be trained rather thinly—i.e., they must not be allowed to become an entangled mass. We have two planted out which have not a tenth the room they require and deserve, consequently the growths become crowded. The plants this year have made growth outside, some shoots having come through the top light apertures, and are rambling over the roof outside, the foliage having a distinct coppery hue, and flowers are produced as freely as inside. It is said to be half-hardy. Who has tried it in a cold house or against a wall? It requires water in summer to keep it growing—a good supply whenever the soil becomes dry. When in full foliage and showing bloom liquid manure may be given, but we do not find it necessary, as our plants grow too freely for their limited space, and we never syringe them.

When the main leaves have fallen the growths may be cut well back, which admits light to the wood retained and to the plants beneath, both being benefited by the thorough exposure. We cut hard back to a joint or two of the old wood any time before March. When extension is required the well-ripened growths of the previous season may be left as long as desired, but it is no use relying on soft growths, as only the well-ripened wood can be relied upon to furnish vigorous free-flowering growths. It is, however, amenable to spur or extension pruning as a Vine, and as satisfactory in results, and the roots have favourable material for ramification and deriving aliment. During winter the soil should be kept dry; but a moderate amount of moisture is necessary to keep the wood plump.

The summer treatment consists in merely regulating the growths as they advance, disposing them equally over the trellis, each having space for the exposure of its foliage to light, thinning out where likely to become too crowded, as when the shoots become entangled it is most difficult to separate them. Judging from what our plants seem capable of I would strongly advise no niggardly allowance of space. Either of them would cover 1000 square feet of space, and give a wealth of flowers in the late summer months.

Propagation is effected by cuttings of small, sturdy shoots 3 or 4 inches long inserted in sandy soil in a propagating frame or under a bellglass. It may also be readily raised from seed in heat.—G. ABBEY.

TOMATOES.

TOMATOES have now become a necessity in most households, and are consumed by artisans in as great a degree as by the wealthier classes, which alone formerly indulged in them. This being the case the spirit of inquiry and trial is abroad, and where a grower was formerly content to have one variety alone he now gives a trial to several. The same thing can be seen in the seed lists, for the varieties multiply exceedingly, each novelty being supposed to be a great improvement on all others. Having somewhat of a mania like the Athenians of old for some new thing, especially in Tomatoes, I gave a trial to several novelties, and I now give my experience of them.

Prelude must lead the way, for its name entitles it to such a position, and it earned its name by being the first to ripen fruit. Our distinguished gold medalist, Mr. J. Wright (whom I heartily congratulate on his recent success) very kindly provided me with the seed of Prelude, and I am very pleased with it, for it is very early, a wonderfully free setter, and the fruit of exceptional quality. The only drawback being that it is small, an attempt to give it more size was requisite, and I note that this has been done at Chiswick by crossing with Perfection. If the productiveness and earliness of Prelude have been preserved with the gain of the Perfection size, then the new variety can fitly be named "Ne Plus Ultra," for improvement can go no further. When obtainable I shall certainly give this new Tomato a trial.

Mr. Peter Henderson of New York very liberally and kindly provided me with several of his novelties, amongst which were Tomatoes Golden Sunrise, Lorillard, and Volunteer. Golden Sunrise is, as its name implies, a yellow variety, and may be termed a Golden Perfection, for it is very similar in growth, size, and shape of fruit and bearing. It is magnificent in appearance, and a dish of its fruit, weighing from 6 ozs. to half-a-pound each, would grace any table. It has a beautiful transparent appearance with perfect shape and in some examples with a warm red blush like that of an Apricot, but bright not dull in colour. The skin is so thin it is

not perceived in eating, and the flavour is unique. All who have tried it pronounce it the best flavoured Tomato they ever tasted. Yellow Tomatoes being not readily saleable I only grew three plants, but I find it in so much demand that I could more easily sell it than the scarlet varieties. It has one drawback, for it is not a good setter and bearer. Volunteer, not so flat but deeper in the fruit than Perfection, is a very handsome bright scarlet Tomato—good bearer, early, and also succeeds out of doors. I prefer it to Perfection in all ways, and strongly recommend it for general cultivation. Lorillard bears a very large good-looking fruit, is a very strong grower, but I did not find it a good bearer, so I shall discard it.

Yorkshire Wonder, sent out as a scarlet variety, turns out to be of the Acme colour. It is of the egg-shaped race, and is of good flavour, a good bearer and setter, and to those who favour this kind of Tomato it will no doubt prove acceptable. It is really no novelty, however, for last year our Rector had the identical variety growing, which he said he had received from friends in Yorkshire, and I told him I should not care to grow it on account of its colour, little thinking I should buy it as a novelty under the name of Yorkshire Wonder, and described as a scarlet-fruited kind.

Laxton's Open Air and Hooper's Conqueror are bearing very heavily, and ripening their fruit outside, and can be recommended highly for such purposes.

Cladisporium has been very troublesome to my plants, and as I never had it before I have come to the conclusion that I brought the disease from Somersetshire, for shortly after paying a visit there, where the disease was bad, my plants were attacked. Perhaps some reader of this can inform me whether this is possible and probable.—H. S. EASTY.

GLADIOLI AT THE CRYSTAL PALACE.

To those who, like myself, highly estimate the beauty of this grand autumnal flower, and have persistently brought it forward in the hope of inducing many to cultivate and exhibit a flower which, despite its drawbacks, is one so well calculated to please the cultivator, the falling off in the exhibitors of the Crystal Palace Exhibition is a matter of very sincere regret. It is true that there was more competition amongst amateurs, and that at any rate one good exhibitor has been added to the list of the few who show there, but it is in the large collections that the great falling off is to be traced. Not only was there no collection from Messrs. Kelway of Langport, who have always set up a grand collection of blooms, but the north was absolutely unrepresented. Mr. Campbell of Gourrock did not put in an appearance, neither did Messrs. Harkness and Son of Bedale, and the collections of both of these firms always formed a large and beautiful feature of the Show. What is the reason of this? I am told that Mr. Kelway is exhibiting at Paris, and that all his energies are devoted to making a display at the world's fair there, and I presume that the northern men do not find it pay. Nor is it to be wondered at. There is but one class in which they can exhibit, and should they miss the first prize the others would not pay the expense, unless they were prizewinners in other classes, of a two or three days sojourn in London, and travelling expenses for such a journey. Nor in a business point of view is it likely to be very profitable to exhibit even for advertising sake. It is not worth taking all the trouble of coming up so far. Amateurs have little to encourage them; they can only exhibit in one class—at least, that is the rule, though perhaps there are ways of evading it, hence to amateurs at a distance it does not offer many temptations, and the exhibitors of other years, Mr. Whitton of Bedale and Mr. Catley of Bath, &c., no longer put in an appearance. And yet what flowers attracted so large a number of visitors as these did? They equal in variety and brilliancy of colour the Dahlia itself, and are certainly far more graceful in habit, shape of flower and spike. They range in colour from pure white to the most brilliant scarlet, and are admirably suited for cutting.

Mr. Burrell's collection of ninety-eight spikes was perhaps not equal to that of last year, and one missed especially the splendid spike of Snowdon, the pure white seedling he exhibited last year, nor do I think he had any seedlings to equal it, although Avalanche, a pure white, and Doris were exceedingly good. Amongst the best of his flowers were—

Abricote.—A lovely flower, pure apricot colour, without any shading of any other tint; the flowers are large, and the spike compact.

Africain.—Dark slaty red on a scarlet ground, a very remarkable looking flower.

Anna.—Brilliant cerise, striped deep carmine.

Atlas.—Large flowers, transparent white slightly shaded with lilac, a fine spike.

Baroness Burdett Coutts.—Very large flowers of a rosy lilac colour flamed with carmine on the lower petals.

Bicolore.—Clear rosy salmon with large white lower petals; a remarkable flower.

Caméleon.—Lilac with dark centre, white blotch, very pretty and compact.

Cervantes.—Rose slightly coloured with lilac, and largely flamed and shaded with carmine, with white lines.

Amitié.—A fine flower, rosy colour with white.

Dahlia.—Fresh rose, shaded and striped with clear carmine, a beautiful flower with compact spike.

Crépuscule.—Magnificent spike of large flowers, rosy lilac, with carmine red flakes.

Enchanteresse.—A magnificent spike of nearly white flowers; the flowers are enormously large, and seem to indicate a fresh start in the flowers.

Grande Rouge.—Brilliant red with large violet spots, an improvement on that fine old flower Meyerbeer, which it strongly resembles, but is larger and blooms earlier.

M. Adolphe Brongniart.—Very old, but still in its style and colour almost unrivalled; the flowers are large, of a beautiful satin rose, with deeper coloured stripes.

Avalanche.—A pure white seedling of Mr. Burrell's, already alluded to; the spike is long, and although the flower is surpassed by Snowdon, it is still a most desirable and effective flower.

Cormie.—Rosy carmine and bordered with cerise, lined with pure white. There were also several of his own seedlings, and altogether the stand was a very effective one.

I do not see why I should write of the amateurs in the third person, and so will at once say that I do not think my stand was quite equal to that of last year, although I had some very fine blooms amongst them, and besides those already mentioned in Mr. Burrell's stand, of which I had several in my own, I had also *Arrière Garde*.—Large rosy salmon flowers, strongly flamed with violet, and with yellow blotch. *Minos*.—Large salmon rose flower, flamed and margined with cerise red, with amaranth in the centre. *Sceptre de Flore*.—Large flowers, white throat, carmine red blotch in the centre, dotted with clear red; this flower was finer this year than I have ever had it. My friend Mr. Lindsell, who is so well known as a Rose exhibitor, came forward for the first time and exhibited an admirable stand of flowers, one spike of Baroness Burdett Coutts being especially fine. The stand which obtained the third prize had not a single name to any of the flowers, a proceeding which I think ought to be discontinued. What is the use of making rules stating that flowers must be correctly named if it is so flagrantly violated? Moreover, it leaves the door open for exhibiting duplicates, and I think ought to entail disqualification.

Some persons may think that my notes are somewhat coloured by the grievous loss* that will make this Show one to be well remembered, but as this is written nearly a fortnight afterwards when I have become reconciled to my loss I think that this notion may be dismissed, and I only wish that I could write more cheerily of one of my favourite flowers than I am in justice constrained to do.—D., Deal.

IN THE MIDLANDS.

ONLY a small amount of space is at my disposal this week, and therefore all that can be done is to record what was noteworthy in three gardens visited, and what was seen between them. Pears and Plums at Impney, barren orchards in a great fruit growing district of Worcestershire, excellent Vine, Orchid, Peach and Melon culture at Abberley, and a beautiful flower garden scene at Witley, are a few of the objects worth dwelling on, as a little that is instructive can be gathered from the cursory examination.

IMPNEY IN SUMMER.

My former visits to Impney have been in the spring, when fruit trees were in blossom outdoors, and forcing operations going on under glass. It is a good garden, at all times interesting, but in summer the fruits of the gardener's work are seen, and the beauty of the surroundings of the splendid mansion appreciated. What the fruits under glass were the excellent competitors at the Crystal Palace shows are aware. In a splendid contest there, with collections of twelve dishes, the Impney fruit bore the palm. I did not think the fine Pine, which was just changing on my visit, could have made such an advance, but the weather was favourable, and though not quite ripe at the show it displayed superior culture. There was no mistaking the high finish of the Muscat Grapes that were hanging on the Vines, and in that respect there was

* The loss referred to, which must be generally regretted, was of a favourite gold watch, value forty guineas.—ED.

not a bunch in the show to excel, if equal, that in the Impney collection. In a single bunch contest Mr. Chaffins would probably have come in first, because of other high qualities with good finish, but for translucency of colour the Impney bunch was unique. Lest these remarks may appear to savour of presumption it may, perhaps, be well to say that I happened to be judging in the Grape classes at the Palace, therefore am not writing at random on this subject. Other Grapes at Impney were also good, and the Peach culture closely resembled that at Ketton, therefore no more need be said on that subject; and I am anxious to direct attention to a bold yet well considered example of root-pruning in Pears, and the striking results achieved.

The wall is 100 yards long, and 14 feet high. The whole surface covered with horizontally trained trees. They have rarely failed to bear good crops of large fruit, but of late have been deficient in colour, flavour, and keeping properties. The roots had gone "down," and accumulations of soil from time to time buried those nearest the surface about 18 inches deep. Two years ago the soil was removed from them to a distance of 3 or 4 feet from the wall, and a mixture of good turfy loam and wood ashes placed in contact with them. Mulchings of manure kept it moist, and the following spring young feeding roots were visible. These were encouraged with further dressings of "good stuff," and by the autumn the new compost was permeated with a mass of fibres. It was then resolved to cut the large roots off at the distance from the wall indicated, and to trust to feeding and the water engine to counteract the check thus given. The roots were sawn asunder, and the ends pared with the knife, more of what had proved good placed round them, made firm and mulched. It was bold action, but Mr. Parker had faith in the power of the new roots to imbibe what was needed, if undue evaporation from the branches and leaves was checked by the free use of the syringe or garden engine in dry weather. After the fruit was set the best on each spur was selected and retained, the others removed; the result of this, with plenty of liquid food, is such a wall of Pears, which, for uniformity of crop, size and colour of fruit, it would be difficult to surpass, and I have seen nothing to approach it this year. The varieties were admirably chosen, presumably by Mr. M. Temple, and the present cultivator has done credit to the collection. Pitmaston Duchess Pears weighed over a pound on September 1st, and will be considerably heavier when gathered.

Near one end of the wall two trees were not treated as above described, the roots were not cut off, and here we find different growth, longer softer shoots, and by contrast markedly inferior fruit. The difference is most striking, and the effect of skilful management is apparent at a glance. The opposite side of the wall facing east is covered with Plums. The well trained trees have been similarly treated, and the long straight branches were roped with fine fruit from base to extremity, and Mr. Parker has reason to be proud of his work.

As no doubt some readers will wish to know how the Chrysanthemums were looking, they can be told in one word—splendidly. Strength with firmness of growth and thick bronzy looking leaves were the characteristics, and no doubt the precursors of first class blooms.

Strawberries in pots near them were equal to the best I have ever seen at this season of the year, and a great deal better than thousands will be two months later in the season.

The terrace flower garden was very beautiful, but all that can be mentioned in it were the glowing rosy magenta beds of Amy Hogg Pelargonium. The variety is seldom seen now, but in masses as at Impney it is one of the most distinct and beautiful of all.

Some Apple trees were laden with fruit, notably Stirling Castle, and there seemed no new outbreak of canker, so Mr. Hiam's insects must have given over eating. Mr. Parker was so pleased with that gentleman's visit, his researches, honesty of conviction, and earnestness, that I regret I could not have a hearty handshake with my literary opponent. He did not, however, convert Mr. Parker to his views.

BARREN ORCHARDS.

Worcestershire is one of the greatest of the fruit-growing counties of England. In a drive of fourteen or fifteen miles there were orchards to the right of us, orchards to the left of us, and trees in the hedgerows overhanging the roads. But ninety-nine trees out of a hundred were fruitless, old orchards and young ones alike nearly destitute of fruit, and the majority absolutely so. The best cultivators are not better off than the worst, though they would have had better fruit if the trees were bearing. Whatever ill effects the last insalubrious summer left behind a terrible hailstorm in May cut off the blossom for miles. It is a sad and dreary outlook, a decidedly bad year for the fruit farmers in that great fruit-growing district.

ABBERLEY.

The "Hundred House," just beyond Witley, is the halting place for Abberley. It is a famous roadside inn, where magistrates' meetings are held, and a favourite rendezvous for travellers. It is 500 feet above the sea level, and a five or ten minutes uphill walk leads to Abberley Gardens, and from thence is a great deal steeper and higher climb to Abberley Hall. Though death brings changes, the successor to the late squire evidently affords the means for the maintenance of his garden and pleasure grounds, and he (William Jones, Esq.) has in Mr. Arthur Young a gardener who will make the most of those means if anyone can, and not spare himself in the effort.

Only a few features of the garden can be alluded to. The chief range of glass is 100 yards long, and comprises five vineries, I think,

three or four Peach houses, and a Fig house. Higher up the hill side is a parallel range, but not so extensive, in which stove decorative plants are grown, with compartments for Cucumbers and Melons. At one end of the range and at right angles with it are two span-roofed green-houses, and at the other end a block of three houses, with a connecting corridor, one for Roses, and two for Orchids. These are nearly new and excellent, with lantern tops and side ventilation below the plants. The gardener's object was to have all the air at command the plants required, and no sharp currents. The condition of the occupants of the houses shows how well their wants are met. Mildew gives no trouble in the Rose house, and apparently nothing else does in the Orchid houses. Richardson's lath blinds are used and much liked, and besides suiting the plants they saved the roofs from being smashed with a terrible hail storm, as hundreds of squares in the vineries were, and Vine leaves cut into shreds.

Under the stages in the Orchid houses are beds of leaves, kept moist, and the plants are in the best possible condition. It is hard to believe they were unsightly imported pieces little more than a year ago. No healthier Cattleyas can be seen, while *Laelias* anceps, albida, and others are remarkable for their vigour. After reading the account of the natural habitats of the plants in one of Messrs. Veitch's serials, Mr. Young suspended the plants from the roof in the Rose house in the summer, letting them have the full sun, and syringed them several times a day. Their growth is remarkable, and stout flower stems are pushing from every pseudo-bulb. All other kinds are also in the most satisfactory state. *Calanthes* are unusually vigorous in strong loam. Most of them are in pots and fine, but a few in wire baskets supported on pots are still finer; and "that's the way," remarked the cultivator, "to grow *Calanthes*." But we must move on.

The Melons in the lean-to range demand mention. A more uniform crop of handsome fruit, of the true Blenheim Orange (no other being grown), and cleaner, stouter plants, could not be imagined. They are thinly trained 18 inches or more from the glass, never shaded, never syringed, and had not a speck of scalding or an insect on them. They are grown in strong loam and lime rubbish, and not dried off for ripening. Such stout dark leaves, every one exposed to the sun, impart to the fruit the best of flavour.

We enter the chief range. The Peaches and Nectarines were gathered except from two trees, and the fruits on these were up to the Ketton standard, thus quite first-rate. Old Vines have been invigorated and young planted. The improvement of the former in two years is wonderful. The roots being in in and outside borders is a great advantage, as one set can sustain the Vines while the others that are raised and placed in fresh soil can take free possession and improve the growth and the fruit. That is what has been done at Abberley with such excellent results. The Black Hamburgs have produced Grapes of the first quality. Strong young rods from old cut-down Muscats have full and heavy bunches. The late house is somewhat of a puzzle, for what is usually the freest and easiest of Grapes to set and finish, Black Alicante, gives far more trouble in those respects than does that splendid late variety Mrs. Pince. It is questionable if this has been seen better represented. If the fine berries in the large full bunches colour well, as they promised, they will equal the best productions of Mr. William Taylor either at Longleat or Bath, and that is more than can be said of any others I have seen in my not very limited travels. The Alicante must be faulty in variety, for the Vines are in the best of health, the crop good, fruit well finished, but the berries somewhat irregular, owing to difficulty in setting, and not such as the cultivator, with his high aims, would desire to see. Allusion to others that are good must be omitted, or some young Vines would have to be passed unnoticed.

Both Mr. Austen of Witley and Mr. Parker of Impney have seen as good Vines and grown as good Grapes as most persons have, and they speak in the highest terms of the Abberley culture. The youngest were planted in March this year, in an inside border—note its size—2 feet 3 inches wide and 2 feet 4 inches deep, the 4 inches being drainage. Now note the size of the canes. The girth was not taken at the thickest part at the bottom, but half way up, as fairly representative, and this was 2½ inches. It must be said they were brown, hard, with the bold round buds the Grape-grower loves to see. The leaves were not 15 inches across, or anything of that kind, and proportionately soft and thin, "like Rhubarb;" but I have no remembrance of any stouter in texture. One, as having practically done its work, was taken off and placed in the scale, which it turned at 1½ oz. It was an Alnwick Seedling leaf from a yearling Vine. Perhaps this method of estimating the value of Vine growth may cause a smile. Be it so, then let the smiler prove it is not a better index of excellence than that of superficial dimensions. I do not know how the weight named compares with others that may be weighed elsewhere, but shall be glad to hear from gardeners who are not afraid to take one from a practically ripened Vine. The removal would do no harm, especially if from the upper part of the cane that would be cut off in pruning.

Vines planted two years ago last February have yielded two good crops of excellent fruit, and others of the same age cropped lightly may be expected to produce superior bunches next year. The soil used in the shallow borders is heavy loam off marl with a free addition of old mortar rubbish and charcoal. A little "Thompson's" has been applied as a top-dressing to the surface covered with stable manure to prevent over-dryness there. Mr. Young is no believer in the rampant system of growing young Vines, but works, as he says, on "Taylor's principle of stopping the leading cane at when 8 or 9 feet long, and pinching the laterals as practised with Vines for fruiting in pots." Mr.

Taylor will not claim to be the originator of the method, though he is undeniably one of its best exponents, and somehow manages to grow much better Grapes than several persons do who have written so much against it. In Mr. Young he has a worthy disciple.

A word must be said on open-air Peach culture. The wall faces south, is 100 yards long and 12 or 14 feet high, I forget which. It is completely covered, without the growths being overcrowded, and from end to end and top to bottom there was a fruit where it was wanted—no blanks. The thinning had been severe, leaving the fruits 15 or 18 inches asunder, the number then fully equalling all requirements, and the fruits being finer than if the crop were heavier. Surface roots by mulching about 5 feet from the wall, with periodical waterings as required, and not an insect allowed on the trees, are the leading points in the success attained, aided probably by a glass coping. Just as I was leaving, a Merryweather engine and 200 or 300 yards of hose were being put into action for the trees.

Young hardy fruit plantations are growing into bearing, but this is not a fruit year in the district. I noticed several apparently new, yet at the same time apparently healing canker specks on some of the trees. We felt sure they were not caused by insects, and Mr. Young was speaking of sending some examples to Mr. Hiam. I wonder if he has done so. If he has not I hope he will, for I am willing for this to be a test case as to insects being the originators of the wounds or not.

Nothing can be said about the pleasure grounds, conservatory, remarkable memorial tower, and other features of Abberley, beyond Mr. Parker's remark on leaving—"The place is well worthy of a visit by gardeners, and a credit to master and man."

WITLEY.

From the heights of Abberley we look down on Witley, a mile distant, the splendid mansion of the Earl of Dudley being situated in a richly wooded vale. The golden dome of the church which adjoins the Court is a conspicuous feature in the landscape as it glitters in the sunlight on a bright summer's day. Witley is as different from Abberley in its characteristics as it is possible to conceive. The miles of drives are level, or nearly so, firm, smooth, clean, with superb lawns beautifully kept, and neatness and high order everywhere prevailing. Witley is not a "fruit place." Pines, Melons, Tomatoes, and Cucumbers are well grown in houses and pits, and a good collection of hardy fruits outdoors, but little on the trees beside leaves this year. Vegetables are grown in enormous quantities for the household, and there the work of utility ends.

Witley is essentially a "flower place." Of these Lady Dudley is an ardent admirer, and her taste in floral decorations is proverbial. No mixtures in room or table adornments are permitted, but one kind alone for each vase, and one alone for the table, varying according to seasons and circumstances, is the prevailing rule. Thus variety is combined with individuality, and in that way the flowers employed give the greatest satisfaction. There are good ranges of plant houses, and supply pits well filled with well-grown plants, and it is thought if ranges of glass were erected for Vines, Peaches, &c., her ladyship would want them all filled with flowers. "Fruit can be bought, but flowers must be grown at home," is evidently an established idea, and the best of the former that can be obtained Mr. Austen has to procure. It was a new experience to a gardener accustomed to grow the best, but he has settled down to it, and is no doubt very happy in his delightful home with its beautiful surroundings. There are flowers everywhere for cutting, acres of Violets, Roses, and other popular kinds, admirably stocked herbaceous borders, great batches of plants and shrubs in pots for forcing, and a few thousands of Chrysanthemums, evidently in charge of an able cultivator.

But the flower garden is the pride of Witley. It is situated on two sides of the mansion, south and east enclosed by a balustrated wall. The extent of the ground is about 10 acres. It is surrounded by a walk, flanked with the choicest of Conifers, golden columnar Biotas, dark Yews surmounted with golden balls, Araucarias, and other appropriate specimens that cannot be enumerated, the whole evidently having been arranged with great care, and from the time of planting till now received the best of attention. The ground slopes from the mansion to the centre, then rises again to the opposite extremity, whence golden gates open to the park beyond, and there in contrast to the art within stand gigantic Oaks of great antiquity, relics of the forest primeval. On the slopes of the undulating lawn, which is faultless in character and keeping, are beds of evergreen and flowering shrubs, masses of flowers that "tell" in the distance—Tritomas, Marguerites, Japanese Anemones, Dahlias, and others suitable for the purpose. There are neat carpet and effective flower beds near the walks, and here and there marble vases tastefully occupied with appropriate plants.

Near the centre of the two sections of the garden are fountains such as cannot be seen elsewhere in this country. The garden is open to visitors by arrangement, and Lady Dudley, seeing a party of about twenty persons, kindly thought they would like to see the fountains in action, and gave the order accordingly. It was a brilliant afternoon, the flower garden just at its best, and when the water rose high in the air with a rushing sound, and the great arching streams appeared from one fountain, and cascades rushed down the other, a diamond fence of water springing up round the margin, the scene was surely one of the brightest and fairest that "ever the sun shone on." The mansion with the handsome conservatory and church form an imposing architectural pile, and abundant relief to the handiwork of man is afforded in the individual specimens and bold masses of contiguous trees.

Near the mansion commences what is known as the Wilderness—a long twisting dell, with handsome Conifers on the slopes, including a beautiful example of Prince Albert's Fir, *Abies Albertiana*, the noblest trees of *Pinus Nordmanniana* I have yet seen, rich deep green Douglas Firs, a heavy background of deciduous trees, and here and there round beds of *Hypericum calycinum*, studded with the golden many-anthered flowers, the growths cut to the ground yearly—evidently the right method for producing cushion-like masses of blooms. Then we go on to the nursery, an enclosure of 8 or 9 acres, where all sorts of trees are raised, vegetables of different kinds grown, and even here large breadths of flowers for cutting to meet what must be the enormous demand. Mr. Austen has a great charge, and is equal to it. One of the most undemonstrative of men, he is ready to do a kind act when he can, and the last of these of which I was the recipient was a twelve-miles drive into Worcester.—W.

WATSONIA IRIDIFOLIA, VAR. O'BRIENI.

WATSONIA IRIDIFOLIA, and several varieties have been known in English gardens for the greater portion of the present century, and

FIG. 34.—*WATSONIA IRIDIFOLIA*, VAR. O'BRIENI.

W. iridifolia var. *fulgens* is a brilliant companion for the beautiful *W. rosea*, which was only recently certificated by the Royal Horticultural Society, and represented in this Journal, p. 225, September 12th last. In the variety now depicted (fig. 34), however, we have a most useful and charming addition to the Watsonias, and it further possesses the claim of being the only pure white Irid known. When exhibited before the Floral Committee of the Royal Horticultural Society at the meeting held at the Drill Hall on Tuesday, September 17th, it was at once awarded a first class certificate.

Mr. J. O'Brien sends the following particulars concerning it:—"The history of *Watsonia iridifolia* O'Brieni is that a correspondent of mine in the Cape found it as a single plant among many hundreds of coloured *Watsonias* of all shades. My correspondent, who was an ardent lover of Cape bulbs, and knew them well, immediately recognised it as a new plant. He took it home and again flowered it, and all the people who knew such things marvelled at it, for it was deemed impossible to ever get a snow white *Watsonia*. It increased to some six or eight bulbs or corms, which I acquired, and which at that time (last year) represented the entire stock. Still I had no faith in it, as I knew a variety of *Watsonia* called white, but which was not so—indeed neither white nor rose, but white washed with rose. In order to test mine severely, I put all the bulbs in one large pot, in turfy loam, and placed them outdoors in the shade. I had several spikes, two of them having several branches, and one 4 feet in height bearing fifty-four flowers, the largest of which were 3 inches across the segments, and 3 inches in length. Speaking from memory, it is the first instance I have seen of a snow white Irid. In old lists the species enumerated under *Watsonia* are various, and many of them mentioned as coming from the tropics, not *Watsonias* at all. One of the lists includes *Anthericum Liliastrum*."

TREATMENT OF SOILS AND MANURES.

THE tests that I gave on page 173, to prove the quantity of soluble matter or salts, give so far a fair and good test of what is really ready for plant life, and the different processes I gave also proved what could be made soluble by cultivation. Metallic elements in combination with oxygen form bases, and bases combined with acids form salts. This is the form that most of the plant foods take in the earth. Some of the salts are more soluble than others. I am convinced that it is of little importance whether the salts are soluble or not, and it is a surprise to me that most of the manure manufacturers should waste so much time and money in making most of the ingredients soluble, when the plant has the functions for making all insoluble salts soluble.

As plants of different kinds require different salts, and more of them than others, it is necessary for the gardener to make the best use of what he has by him. This is one reason I have said so much against artificial manures, that the majority do not know the requirements of the plants and the deficiencies of the soil, and it is a thorough knowledge of these two things that all gardeners and farmers should cultivate, so as to make the best use of manures, whether artificial or otherwise, not to waste on one piece of ground what is useless, and what would be beneficial upon another.

I will suppose for the present that the requirements of the plants are understood, and not the resources of the soil. Manure of the sort to suit the plant may be lavished upon the ground already rich in the particular elements required.

In other instances the soil may be rich in some elements to suit certain plants, yet the ground may be planted with some crops that require more of a different element, while plants requiring those elements present may be planted on another piece of land very poor in them. If this knowledge is promoted thousands of pounds would not be wasted, but placed where required and in proper quantities.

If the manures that are soluble are used with that knowledge, and also with the knowledge of when to apply and store them, it would take a great deal of responsibility away from those that make and recommend them. I have known superphosphates used by the ton on land full of calcium and phosphorus, and had good farm manure been used and the land well worked a balance might have been at the bank instead of the reverse, and when we consider that a thousandth part is all that is present in the dried plants, does it not seem absurd to waste so much on phosphorus?

It will be as well to give a few hints as to the manures, &c., recommended by me, the crops that they suit, and the different soils that require them. As Potatoes are one of our first crops in the garden, a good crop of fine Potatoes is of the first importance, though technically not one of the greatest difficulty. Potash forms an important ingredient, sulphuric acid, phosphoric acid, and a smaller quantity of magnesia. If the farm manure is treated as directed by me in my first article, and a good dressing is given the soil, together with a few barrowloads of the blood mixture and ash of waste heap, the soil will be prepared with sufficient food to produce an excellent return of Potatoes. To a certain extent the parent soil acts a prominent part in the quality of the production, and if it is a stiff clay the best means to obtain good Potatoes in quality is to ridge the land, which acts as a drain for all the surface water; of course, the land itself should be permanently improved, which if done in a proper way would soon enable the gardener to plant in good arable land. The ridge would have the opposite

effect in dry weather. Good light soil suits Potatoes, but failing that the best use must be made of the others by judicious treatment.

A similar manuring of the soil will suit Beans, as potash plays first part with over 40 per cent., and there is over 30 per cent. of phosphates, but if the soil is not calcareous an addition of a small quantity of gypsum will supply the required quantity of sulphuric acid and lime. Parsnips have over 36 per cent. of potash, 18 phosphates, 11 of lime, &c. The same dressing will do for Parsnips with the addition of more clay or lime. Carrots, phosphates 10 per cent., potash 32, soda 13, sulphuric acid, &c. As more soda is found in the ash of Carrots than in any of the foregoing, the ash of marine plants (Seaweeds) or the cesspool water or mud that drains from the kitchen or laundries will supply the extra quantity of sodium if not present in the soil. Cabbages contain in their ash phosphates 13 per cent., potash 12, lime 20, sulphuric acid 21, soda 20, &c. This analysis shows the necessity of preserving all our manures in a proper or semi-dry state, and all the refuse from the garden should be mixed with it. There may be enough of most of the mineral elements in the soil for all practical purposes, but to be doubly sure it is as well to preserve all that is in the refuse and manure. Beet contains potash 24 per cent., soda 19, salt 24, phosphates 4, &c. If a good dressing of clay can be given to very light lands it will be found to supply a great want for this crop, with a fair dressing of ordinary manure or agricultural salt will not be a waste. Turnips have in their ash phosphates 10 per cent., potash 28, salt 10, and lime 23. This proves that only two of the principal garden crops require any lime in large quantities, and if a dressing of lime or chalk is given for the benefit of Parsnips and Turnips together with the ordinary dressing sufficient lime will be left in the soil for all the crops to follow till one or the other is again planted or sown there. The dressing for these crops must depend a great deal upon the nature of the soil. It would be a waste of time to put lime upon the soils already rich in them, and the only cases where it is required is on light soils full of humus and stiff clays to improve its texture. When we consider in some instances the ash is only half the per-centage of the plant, the quantity that need be supplied must be small, and more so when we know that ash left is not when in the plant capable of being thrown off into the atmosphere in a volatile state, but all the mineral that constituted the foundation of the plant remains fixed in the fire, and when we examine the soil and find it consists largely of mineral or inorganic elements it is not surprising that those who work the land most get the best results independent of what is put into it.

I was on one estate seven years, and during that time not 1 lb. of artificial manure was introduced, in fact no manure of any kind from outside, and the only manure procurable was long straw that horses had slept on once or twice. I now know to a certain extent that it was useless, as the soil was full of silica and did not require it from that source. This straw was mixed with leaves, and the cesspool water, which was the colour of stout, was thrown over till it presented the appearance of well trodden farmyard manure. There was plenty of it, and it was supplied to the land in good dressings. Finer crops of all sorts of vegetables and fruit could scarcely be produced. I may say the same with all classes of indoor plants, which receive nothing more than the liquid and a little soot. Finer Crotons, Dracenas, in fact all stove plants, with Pelargoniums, Strawberries, Cinerarias, Calceolarias, Chrysanthemums, and all classes of indoor plants could not be seen anywhere, and Peaches and Grapes were excellent. On another estate any quantity of guano, clay, bonemeal, Standen's, and almost every kind of manufactured manure, with nitrate of soda, sulphate of ammonia were used, yet taking all round nothing like the return was given notwithstanding all this expense; in fact, if the supply was not constant a difference in the plant was perceptible at once. Some of the soils that gardeners have to use are more often than not procured from some out-of-the-way corner, and are practically barren. This soil needs well mixing with something that has been exposed to the air by constant working, and with some manure rich in nitrogenous matter. Plenty of leaf soil is one of the finest ingredients to mix with all soils, as it would supply most of the elements required.—G. A. BISHOP.

I THINK Mr. Bishop is unscientific and inconsistent in his treatment of this subject, as I may be able to explain, though I do not intend to take all his statements and reply to them seriatim. In the first place he classes soils as active, dormant, and inactive or latent; then goes on to say the larger part of the soil being inorganic proves that the mineral elements are far in excess of that required by plants, and that it is possible to exhaust them by continuous cropping without a sufficient return of these elements. How he can come to these conclusions after having previously stated that one part of the soil is a mass of elements in a latent

state I am at a loss to know. As these latent elements, according to Mr. Bishop's own explanation, cannot be absorbed by plants, therefore the farmer must have always a certain amount of plant food in the soil, latent or otherwise. Moreover, in the same paragraph he refers to a farm where the land has had no return of the constituents carried away from it, yet for the last forty years it has produced from 20 to 24 sacks of corn per acre each harvest. I should be glad if Mr. Bishop could inform me where these inorganic substances had been obtained for the growth of the Wheat, seeing that by his theory the continuous heavy cropping of the land would have thoroughly exhausted the plant food years before some of the later crops were gathered, Wheat being one of the most exhaustive of crops to the soil. Upon the strength of this experiment he appears to recommend a course of working and tillage operations that would serve in the place of adding manures. Surely this is not the same writer who in the early part of his paper says, 'Land is exhausted by heavy cropping without returning any of the plant constituents.' If so, I will leave the reader to judge if it is consistent with his theory of exhaustion of soils.

I quite agree with Mr. Bishop in his endeavours to call all the natural agencies to the cultivator's aid, and to employ all the waste materials, both vegetable and animal, for improving the fertility of soils, yet I think his disregard of artificial manures is presumption as well as the assumed scientific manner in which he attempts to treat the subject. With regard to the letter by Mr. Tonks, p. 174, though I agree in most points with his treatment of the scientific part of the subject yet I think the idea of his accomplishing such striking results from the handful of properly compounded artificial manure would be something like populating a large town with a few important families, as he would be unable to tenant all the houses, so in the same manner would he be unable to get the plant food thoroughly distributed in the soil. We must remember that one advantage of farmyard manure (though apparently a disadvantage) is its bulky nature. In consequence of its bulk the fertilising ingredients are able through the medium of the straw, &c., to be diffused equally through the soil. Also this manure has important physical as well as chemical action in the soil. Artificial manures can never stand in the place of good stable and cow manure, but their value is abundantly proved when supplementary to farmyard manure to show any practised man that its use is highly profitable and in some cases almost indispensable. Nevertheless, the subject affords ample scope for practical and scientific discussion, and also one that is interesting to all engaged in the cultivation or management of land.—W. S., *Lancashire*.

INSECTS OF THE FLOWER GARDEN.

(Continued from page 86.)

CATERPILLARS, even if handled so as to annoy them considerably, rarely attempt to defend themselves by biting, but one of the few that will try to grip the human skin is that of the buff-tip moth (*Phalera bucephala*); it is not, however, able to do this. One of these caterpillars is not unfrequently to be seen on a flower bed bearing a hungry aspect, and suffers death as an insect pest (we cannot say unjustly), for the species does much damage to trees, which they sometimes strip till the trees appear as bare in August as they might be in October. Often feeding in companies upon Limes, Elms, and other trees planted along walks or avenues, they are apt to be dislodged by high winds, and then wander off over beds and borders, seeking a change of food or a place where they can enter the pupal state. The chrysalis, which is dark brown and curiously spiked at the tail, may be detected now and then amongst the surface earth, and should be destroyed. An insect which appears to have been getting common lately, the figure-of-8 moth (*Diloba cæruleo-cephala*) has been occasionally taken on garden Roses, but it prefers the Hawthorn or the Apple. The mother moth lays its eggs in September at the base of a twig; the caterpillars feed during May and June. They are of a peculiar smoky green studded with black warts and having small bluish heads. Evidently they are regarded by birds as choice morsels, which is fortunate for us. Passing on to the large family of the Noctuidæ we have before us a group of moths notable because of their liking for sweets, hence they come eagerly to our flower gardens in the dusk of summer and autumn, drawn thither by the attractions of fragrant species, in which they seek for honey, not always successfully. Certain kinds are specially resorted to, such as the Honeysuckle, Petunia, Phlox, Stocks, Peas, and some *Pelargoniums*. That they perceive at a long distance off any odour which is appetising is an unquestionable fact, however it may be explained. I have seen myself instances where sugar was being used to entrap moths, and species turned up which must have travelled more than a mile from their known locality. Only a few

of these moths feed up in gardens while in the caterpillar stage, and they may be accounted welcome visitors, because, as I have previously shown, their doings assist the fertilisation of some flowers.

The conspicuous caterpillar of the grey dagger moth I have taken off Roses, and it will now and then turn up in gardens, feeding upon various shrubs. It grows during August and September; the moth (*Acronycta Psi*), which is notable for markings, which are supposed to resemble in shape either a letter of the Greek alphabet or a dagger, emerges in the following spring. Like others in the genus the caterpillar is slightly hairy, some of the hairs being long, others short, striped from head to tail with black and yellow, having also some red and white spots, but specially distinguishable by its two humps, one near the head, which is long and slender, the other at the short and flattened. This is one of those caterpillars best dealt with by handpicking; it appears to escape birds, nor is it much troubled by the attacks of parasitic insects. The caterpillar of a moth in this division, possessing the odd name of the brown-line bright eye (*Leucania conigera*) from its singular markings, is of some service to the gardener. Though it can eat several grasses its preference is for the couch grass, a too well-known nuisance, upon which it feeds freely at night in the spring, hiding itself during daylight.

We come next to a species, the caterpillar of which I have several times had brought to me by gardeners, who appeared to regard it as somewhat of a curiosity, and different to the common herd of these devourers. The dot moth (*Mamestra Persicariæ*) is an insect allied to the too abundant Cabbage moth (*M. Brassicæ*), but though its caterpillar may occasionally be noticed in the kitchen garden and orchard too its favourite haunt is the flower garden. If the moth be noticed on palings or hovering at flowers in the summer it should be captured; it is conspicuous for the spot of pure white with a central cloud, which shows up on the wings of dark brown. The caterpillar is nearly 2 inches long when fully grown; the colour varies from green to brown, the head being pale and shining, from head to tail there extends a series of V-shaped markings, the points of these are directed backwards, the last ends in a roundish hump. If alarmed it immediately quits the food plant and rolls into a ring. In habit it is solitary, feeding on many species of plants. I have seen it devouring Stocks eagerly, and from finding it on *Pelargoniums* in houses as well as in beds I infer it is partial to those plants. The allied species referred to above and named from the Brassicas it so persistently infests is not, however, limited to these vegetables. Its dingy but very variable caterpillar also occurs amongst our flowers, mounting sometimes to the lofty Dahlia, and at other times condescending to the humble Marigold. In turning over the soil at the end of the season the brown chrysalis is frequently unearthed; it is one of the objects for which poultry scratch eagerly.

The Turnip moth (*Agrotis Segetum*) bears a popular name that indicates certainly one vegetable the caterpillar frequently attacks, but it fails to give an idea of the general destructiveness of the species: in fact, the late Edward Newman believed it to be a caterpillar which would eat any plant were it but tolerably succulent. In June the greyish brown moths are on the wing, in appearance bearing much resemblance to others of the same group; but their habit of settling upon the ground to deposit their eggs serves to draw our attention to them, and this they will do on the flower beds as well as elsewhere soon after dark. About their proceedings this entomologist remarks:—"Very often in a bed of China Asters the leaves of a plant here and there will be found withering, and you become aware it is dying, but cannot tell why. Just examine the stem where it enters the earth and you will find it completely decorticated; the circulation of the sap has been prevented, hence life is destroyed. This is the work of *Agrotis Segetum*; you pull up the Aster to find the enemy, but fail; his depredations were committed in the night, and before daybreak he has wandered away several inches or even feet." This propensity it has for attacking plants at the foot of the stem makes it a most injurious caterpillar, and so, too, its habit of committing devastation amongst seedlings. For the protection of these the usual applications, such as lime, soot, and ammoniacal liquor diluted, which check the progress of surface feeders generally, may be tried when the caterpillars are hiding in the soil. They are difficult to kill, and what makes matters worse they continue to gnaw the roots of herbaceous plants throughout the winter. This caterpillar is plump and glossy with a small flattened head, behind which is a horny plate; the body is brown dotted over with darker points and faintly striped. Its digging operations are aided by powerful muscles in the legs. In the genus *Agrotis* there are several other moths, the caterpillars of which feed upon garden weeds, and to some degree they may be deemed useful, for few gardens can be kept quite weedless.

The caterpillar of the great yellow underwing (*Tryphæna*

pronuba) is sure to be found amongst some of the plants in the flower garden when there is any extent of ground adjacent which is devoted to vegetables. It buries deeply during the day, but comes forth at night, feeding upon bulbs or tubers if it can obtain them, and lives in this way from autumn till early summer. Its relative, the lesser broad-bordered yellow underwing (*P. janthina*) is fortunately not very abundant, for it kills some of the plants on which it feeds by eating through the stems. When it appears in a garden the object of its attack is mostly an *Auricula* or *Polyanthus*. The moth which emerges in the summer is a beautiful insect, though of moderate size.—ENTOMOLOGIST.

EVENTS OF THE WEEK.—To-day (Thursday) the Vegetable Conference at Chiswick will be resumed at 2 P.M., when the papers to be read will be as follows:—On "Food of Vegetables," by Mr. J. Wright; on "The Improvement of Peas during the last Quarter of a Century," by Mr. T. Laxton; on "The Improvement of Potatoes during the same Period," by Mr. A. Dean, and "How to Maintain a Supply of Vegetables for Family Consumption throughout the Year," by Mr. J. Smith, Mentmore. The usual sales will be held by Messrs. Protheroe & Morris and J. Stevens.

THE WEATHER.—Several slight frosts have completed the damage to tender outdoor plants commenced on the 17th inst. In the low-lying districts around London Beans, Dahlias, and Vegetable Marrows are totally destroyed, and the leaves of many trees are falling fast. The days have generally been bright and warm, and favourable to the ripening of the fruit still hanging on trees. Mr. T. H. Slade writes from Stockwood Park, Luton, "On Tuesday heavy rain fell throughout the day, a cold wind prevailing, but on Wednesday it was much brighter. We registered 5.3° and 5° of frost on the 17th, 18th, and 23rd respectively."

THE abundance of WASPS has been remarkable, many persons having been stung, but with no serious result; still, I am of the view which I have long maintained, that the wasp has no greater inclination to sting than has the bee as a tribe, only the wasp more frequently comes into collision with humanity, owing to its desire for sweets in general. Flies of the ordinary species have been far below the average this autumn in point of numbers, and possibly we have to thank the wasps for this. It is certain they seize upon flies and a variety of other insects, which is some set-off against the mischief they do to fruit, and the annoyance they cause to many tradesmen.—ENTOMOLOGIST.

THROUGH the exertions of the leading members of the WAKEFIELD PAXTON SOCIETY that town has recently secured a recreation ground of about 3 acres, which was recently opened to the public, and it is expected that other open spaces will shortly be obtained there.

MR. J. ROBERTS, The Gardens, Tan-y-Bwlch, Merionethshire, sends two small cones of *EUCALYPTUS GLOBULUS* from trees nine years old from seed, and wishes to know if it is not rather unusual for such young trees to produce seed.

GARDENERS' ORPHAN FUND.—We are desired to state that the Chiswick Gardeners' Association will give a concert in aid of the above Fund at the Vestry Hall, Chiswick, on October 31st.

MR. W. HALL, Secretary of the Brixton, Streatham, and Clapham Horticultural Society, writes:—"Herewith I beg to inform you that the Society's next Exhibition will be held on Tuesday and Wednesday, November 5th and 6th, and not on the 12th and 13th, as previously announced. This alteration has been made to prevent the Society's Exhibition clashing with that of other societies." The alteration does not seem to have quite effected the intended purpose, for it is to be held on the same days as the Royal Horticultural Society's Conference and Exhibition at Chiswick.

I SEND you a sample of ONIONS, the name of the variety I do not know. The seed was given me eight years ago, and I have always planted a few and saved seed, having invariably had sound Onions of the preceding year when the current year's crop was harvested. The

enclosed are samples of their keeping qualities. My mode of procedure is to pull them as other people do, and dry them a few days on the ground, but take them in if rain threatens. When perfectly dry we tie them in bunches of from eight to fourteen, according to size, and remove all the loose peel, laying them on boards in my potting shed. In a few weeks another skin is often loose, and in ropeing them, as we call it, that is removed. I thank you for all the information received from week to week in our Journal. I am amongst the oldest subscribers, but not the oldest. The first number I never saw, but I began with No. 2, and have continued ever since.—ECCREMOCARPUS. [The Onions received were small but remarkably well kept. We hope you will continue reading the Journal for some years.]

GILBERT'S SURPASSE TOMATO.—This has proved a really first-class variety for outside work here. Last year was a very bad one for outside Tomatoes, and Surpasse was the only one that ripened with us. This year it has done remarkably well, producing large clusters of fine fruit, beautiful shape, and very heavy, having very few seeds. Another season we shall use it more extensively. From some cause it has not done so well with it under glass; perhaps it requires more air than most varieties, but as an outdoor Tomato it is excellent.—S. T. W.

HAVING about 700 feet run of glass devoted to PEACHES and NECTARINES, under my charge, will "Utilitarian" allow me to give my opinion with regard to his fruit falling? In my early house at the end nearest one of the doors is planted an Elruge Nectarine, and this year the fruit commenced to shrivel and fall at the top of the tree. But luckily I noticed it in time, and attributed it to cold draughts and insufficient water at the roots, an opinion our head gardener fully endorsed; so after watering copiously, and ventilating carefully, we gathered 400 fine Nectarines from this tree. No doubt the sunless season of 1888 was very trying for Peach growth.—FOREMAN.

PEA WILLIAM HURST.—At the commencement of the sowing season my friend Mr. Easty kindly sent me a large packet of seed of this variety, and strongly recommended it for early sowing. Having sufficient dwarf Peas in stock, I decided to keep it for late sowing, and am well pleased with the result. We sowed the seed during the first week in July on Celery ridges, but find we did so fully a fortnight earlier than we need have done. At the present time we are gathering good dishes of Peas, the pods being well filled, colour and quality also good, and if the birds can be kept off several good pickings will be available during the next fortnight. William Hurst only attains a height of about 15 inches, and is very productive. No stakes are needed, nor for any other dwarf or medium height variety sown late.—W. I.

CATERPILLARS AND FRUIT TREES.—On page 256 reference is made as to when we put the grease bands on fruit trees. By looking at my note book I see we commenced on the 20th October, 1888, but as previously stated in the Journal our fruit trees were more seriously attacked by caterpillars than ever before. During the time the grease bands were fresh and sticky the female winter moths were depositing enormous numbers of eggs on the trees. To account for this I think the winged male moth must have conveyed the wingless female over the obstacle to her ascent. Great numbers of both male and female moths were caught in the grease, yet in spite of that the foliage and bloom was destroyed on nearly all the trees. A timely warning is given to "R. R."—viz., not to apply grease to the bark. Our trees had paper bands thickly smeared with ordinary cart grease tied round them, and where the grease touched the bark it appears now as if canker would ensue. My employer and I are not inclined to try the experiment again. Good cultivation, perfect cleanliness, and keeping the soil constantly moved about the trees, so as to give the insects no rest in the ground, and poultry not overfed running about, will in the long run prove as good a remedy as most.—S. T. WRIGHT, *Gleyston Court Gardens*.

LIQUID MANURE IN WINTER.—The same correspondent writes:—"I think the leader in last week's Journal the best I ever read. Mr. Hollingworth of Woodseat, well known as a Grape grower and exhibitor, acts on the system with his Vines. My old master, Mr. McPherson, also acted on it, and I do myself, and know how well it answers." It may be added that the writer of the above note is an entire stranger to the writer of the article referred to.

GAS LIME AND THISTLES.—I have recently had a piece of ground given over to me, which is situated at some distance from the gardens. I intend cropping half of it with Potatoes every year to maintain the supply until November. Our garden being an old one Carrots and Parsnips are, as a rule, destroyed by maggot

every year. I therefore propose devoting the remaining half to these crops. There is an enormous lot of Thistles in the ground. Clearing them out of the ground is out of the question. I am led to wonder if gas lime would kill them. If so I should be glad if any of your correspondents that may have had any experience with gas lime would tell me when and at what rate to apply it. If gas lime will not kill them is there any other effective remedy? If so I shall be glad to know of it. The ground will be cleared in the course of a fortnight, and of course will not be planted until next March. It is about an Irish acre in extent. Some Potatoes I have in it this year are badly scabbed, otherwise the quality is good. Would gas lime remedy this defect? Would any manure be required in addition to whatever application is suggested?—HANDY ANDY.

— THE past summer in NORTH WALES has been a trying one for the vegetable gardener. Enemies on all sides have had to be combated, and that in no faint-hearted manner. The season commenced with an invasion of slugs, which attacked almost anything that was green. Jerusalem Artichokes went down before them, and it was only by the greatest care that seedlings could be preserved. Peas, especially early sorts, germinated badly, and what did come through the ground, in spite of repeated dustings of lime and soot, were made all the thinner by slugs. We have had to sow about twice the quantity of seed to keep up the supply that we should have done in an ordinary season. Veitch's Perfection and Dickson's Favourite are the only sorts that have really done well. During the latter part of May, and all through June, we did not have a single thunder shower, and it was only by mulching and indefatigable watering that Peas could be kept bearing. Mildew attacked them in the earlier stages of growth, and spread more rapidly than in any season I can remember. Last year being so unfavourable to the maturing of seeds in general, undoubtedly impaired the vitality of Peas; hence the fungoid attacks which have been prevalent in so many parts of the country. Onions in many gardens this year are next to a failure, especially when seed was sown early. In our case we reckon to have about a third of a crop. The ground being in good condition the seed was sown at the end of February. The cold, sunless weather which followed, with seed not too well matured, was all against its germinating. I am afraid that many of us after the turn of the year are too anxious to get seeds in the ground that would be better left for another month in the drawer. Parsley we sowed half a dozen times, with the result that we did not have two dozen plants. Our present supply is derived from the previous year's seed, which as a final resort we sowed in heat and transplanted, but was long in coming through the ground, and the rows are patchy.—D. G., North Wales.

CHARACTERS IN BRITISH FERNS.

[Read before the Sheffield Floral and Horticultural Society by Mr. John Eadon.]

THE lovers of Nature are constantly brought into contact with the pleasing phenomenon of variation. It is generally accepted that variety is charming, and it is my intention to show how far, and in what way, this charm of variety can be claimed by our British Ferns. For beauty and gracefulness in foliage we have no other class of plants to compare with them. The fixed characters of British Ferns are divided into eight classes—namely, 1, Plumose and Frondose. 2, Divided and Decomposite. 3, Imbricate and Crispate. 4, Lax and Flexuose. 5, Deltoid and Brachiate. 6, Cruciate. 7, Interrupted and Deficient. 8, Crested and Ramosc.

The eight characters named above are all to be found in the following four species—namely, *Athyrium Filix-fœmina*, *Blechnum spicant*, *Polypodium vulgare*, *Polystichum angulare*.

There are seven other species in which one to seven of the above-named characters are to be found:—*Adiantum Capillus-Veneris*, *Allosorus crispus*, *Hymenophyllum Wilsoni*, *Lastreas*, *Osmunda regalis*, *Scolopendrium*, and *Pteris aquilina* or common Brake.

The last is the most unlikely plant we should imagine to exhibit any special characters; but I have seen it crested and ramosc, imbricate and crispate. The *Osmunda regalis* is not given to much change, but there are several varieties of it, the most to be admired being the crested, of which we have more than one type. *Polystichum Lonchitis* has been found crested. *Allosorus crispus* has also produced a crested variety. There are also some beautiful varieties in the *Asplenium* class. *A. marinum* has given us a grand plumosum, also crested and ramosc varieties. *A. lanceolatum*, *A. nigrum* and *A. trichomanes* have each produced good varieties.

I will now bring before you some of the beauties referred to in Class 1—namely, Plumose and Frondose. The first to claim our attention is the lovely *Athyrium Filix-fœmina* *Kalothrix*, a name expressive of the fineness of its divisions, and meaning beautiful hair. The late Colonel Jones, when referring to it said, "It is, perhaps, the most delicately beautiful of all Ferns." The next is a good plumosum of my own raising from a plant which I found, and there are also many others;

but we must content ourselves with referring to one or two in each class.

The plumose character is represented in the *Lastrea Filix-mas* group by the beautiful plant, *L. Filix-mas* *Bollandiæ*, a good variety, which is said by some to be barren, like many others of the plumose class, but the old plant that I possess produced spores last year and again this.

The next to be noticed are the most beautiful, and at the same time most useful, *Polystichums*. The pulcherrimums in the *P. aculeatum* division are among the most charming of our native Ferns. There are also several in the *P. angulare* division. A gentleman named Mr. Moly has two varieties of this beautiful plant, and one is variegated. I look on these plants as worthy to be classed among the gems of our British Ferns. The next is *P. angulare plumosum* *Wollastoni*; it is a fine old plant. I have grown it for a number of years. Here is *P. plumosum* grand. The late Colonel Jones, from whom I received it, said it was "a gem of the first water," and I endorse that opinion. But good as the above are, we have one much in advance of them. I refer to *P. divisilobum plumosum densum*, raised by the late Colonel Jones. The opinion expressed by Mr. C. T. Druery is that this Fern is the perfection of division and delicacy. It has been called the *Todea superba* of British Ferns, and deservedly so. There are many other beautiful plumose and frondose varieties. There is a grand plant called *Polystichum cristatofoliosum*. Another, called *P. divisilobum decorum* by Colonel Jones and distributed by him, is also a lovely Fern. *P. conzestum polydaetylum* was raised by Mr. E. F. Fox, near Bristol, from whom I received it last November. It is a fine plant of the foliosum section.

There are some fine plumose plants in the *Polypodium* class. *P. cambricum* is an old variety, but very good. There is also another of the cambricum group, which, as some say, is far better than the last. This is called *P. Barrowi*. The most plumose of them all is called *plumosum* *Hadweni*. It was found in Silverdale.

Scolopendrium crispum varieties are fine plumose plants; also the undulatum varieties, several of which I have collected myself.

In the cruciate class the first I will mention as representing this character is *Athyrium Filix-fœmina* *Victoriæ*, a plant well known to most growers, and needing no comment from me. *Polystichum aculeatum cruciatum* was raised by Mr. E. J. Lowe from a cross with *P. angulare cruciato-multifidum*.

The interrupted and deficient character is shown by *P. angulare* var. *lineare*, which has been repeatedly pronounced to be a grand plant; but there are many in this division which are anything but attractive.

The next and last class of character to notice are the crested and ramosc Ferns, which is, as some of you are aware, form a very extensive section of our British varieties, for out of the forty-three species of British Ferns we have twenty that have produced crested plants, and in some of the classes the crested section is very strong; but we can only briefly refer to a few. A little gem is *Athyrium grandiceps*, a beautiful and very densely crested variety. *Athyrium pericristatum* (Jones) is small but very good. A young plant of my own raising of the *A. Friselliæ* section is much better crested than most I have noticed of its kind.

The fine old *Lastrea Filix-mas* var. *cristata* is too well known to call for any comment here. Of *L. grandiceps* and *L. polydaetyla* there are a few very good varieties; also a ramo variety, or two—*L. ramosissima* and *L. ramosissima*.

I will next refer to one or two of the *Polypodiums*. In this class there are many beautiful crested and ramosc varieties. Here are two—*P. cristatum* and *P. grandiceps*, both very good and distinct. A few of the best *Polystichums* are *P. grandiceps* (Moly), *P. latifolium cristatum* (Jones), *P. polydaetylum splendens* (Jones), and *P. polydaetylum* (Wollaston), both the last being very choice.

I will now conclude with noticing a few varieties of *Scolopendriums*. I have one of the dwarfiest, the densest, and most delicate in its divisions that I know, and with me it is a free grower; but it must be kept under a bellglass to do well. I also found one last October, and referred it to the late Col. Jones, who advised me to name it *S. trifondosum*. I think it is likely to establish itself as a very good variety.

[Mr. Eadon fully illustrated his remarks with a collection of plants and fronds, for which, as well as for his interesting and able paper, he was heartily thanked by the meeting. The chair was occupied by Mr. Henry Davy, who is also, like Mr. Eadon, a successful and enthusiastic cultivator of British Ferns. The subject of Mr. Eadon's paper, however, being of a special and technical character, did not provoke any discussion. One question was asked, What did he consider the main causes of the changes from the normal varieties? To this Mr. Eadon replied, That it was an inherent principle in Ferns to sport. He also was fully persuaded that we were entering on a new era in Fern culture, as it was now thoroughly understood how to raise new varieties by crossing. But many of the best varieties now in cultivation have been found wild. Different localities produce different forms of certain Ferns; for instance, in one part of the country a gentleman found thirty *Scolopendriums*, all varieties of *crispum*. This gentleman thinks there is something special about the districts which produce these varieties. On the limestone in the neighbourhood of Auston, a village about twelve miles east of Sheffield, Mr. Eadon found special kinds of *Scolopendriums*. In some places you can never find anything different from the normal types. The English lake district is a prolific field for the Fern collector, many crested and plumose varieties having been found there. In some parts of England many varieties of the common Bracken (*Pteris aquilina*) can be found, but nothing different from the ordinary variety can be found in South Yorkshire or the neighbourhood.

The special Polypodies have been found chiefly in the lake district, except *P. cambricum*, which was found in Wales. The majority, however, of the best varieties of Ferns are now raised by crossing, and one of the best hybridisers was the late Col. Jones of Clifton, Bristol.]

STRAWBERRY GROWING.

OBSERVING the remarks of "W. S." on my few notes on Strawberries, I should wish to add a few words to what I previously wrote. I had not overlooked Loxford Hall Seedling, but I only fruited it one year at Totham, and then from very weakly runners, and in moving I lost my stock. Having years ago taken the advice of the American sage never to prophesy until I know, I did not feel justified in speaking positively on the merits of Loxford. It is the neatest grower I ever saw, and has few runners, whilst the few fruit I gathered were very large, late, and of good flavour. I should judge it to be admirable for exhibition, and at some convenient season I must procure plants and test the variety thoroughly, after which I shall be able to record my experience for the benefit of others.

I had the privilege of seeing Mr. Iggulden's crops of Strawberries on yearling plants, and they were plentiful, large, and exceptionally early, and it was mainly for earliness, Mr. Iggulden informed me, that he pursued this system. Speaking yesterday to a market grower who formerly had great opportunities of experience in the gardens of a true "horticulturophile" (if I may be allowed to manufacture a word), he stated to me that the annual system is far and away the best, and the only course he would pursue if he were a Strawberry grower.

I omitted to state that I only apply the cod potash guano when the weather gives me some assurance that it means to give a good down-pour for a day or two, for the manure not being easily dissolved it is worse than useless to apply in dry weather.—H. S. EASTY.

SOME OF THE ANGRÆCUMS.

THE genus *Angræcum* was established in 1822 by Aubert du Petit Thouars, to include certain species of epiphytal Orchids found in East and West Tropical Africa, Madagascar, and the adjacent islands, and in a work published by that botanist several of the species now in cultivation were described. It was then believed that the geographical range of the genus was very limited, but species have since been found in Japan and the West Indies. Their headquarters are Western Tropical Africa, from Sierra Leone to the River Gaboon, the opposite side of the great continent about Zanzibar, in Madagascar, the Comoro Islands, Bourbon, and Mauritius. They are essentially heat and moisture-loving Orchids, and with the exception of the Japanese *Angræcum falcatum* they need the warmest compartment of the structure devoted to such plants. Being epiphytal in habit the majority require to be grown in baskets or on blocks of wood; but those of vigorous habit, such as *A. eburneum* and *A. sesquipedale*, are usually grown in pots with abundance of potsherds as drainage, good fibrous peat and sphagnum, or the latter alone, that moss also being employed when the small forms are grown in baskets or on blocks. As with all Orchids of similar habit and from similar climates, abundance of water is required during growth, and a less amount when at rest; in other respects they may be treated like most of their allies. A few descriptive notes upon the best of the species may be of interest, and will serve to indicate the chief characteristics of the genus.

One of the most remarkable Orchids known is *A. sesquipedale*, and whilst having the largest flowers in the order it is also unquestionably the most handsome in its genus. Such qualities entitle it to some consideration, and several points in its history are also invested with peculiar interest. It is, perhaps, the best known of the *Angræcums*, for it is found in the majority of moderately large collections of Orchids; and very deservedly is it so popular, for the vigorous habit of the plant, the dark green distichous leaves, and the great ivory white flowers render it worthy the attention of all growers. In the ordinary type of the species the flowers are about 6 to 8 inches in diameter, the spreading sepals and petals imparting a star-like appearance to them, and the spurs are from 10 inches to 1 foot in length. Messrs. Veitch & Sons have a grand variety, which is, I believe, named *superbum*. It is greatly superior to the ordinary form, both in the size of the flowers and the purity of the white. In both the flowers are borne on a moderately short peduncle, and are arranged in a racemose manner, but widely

spreading. They are produced during the winter months, and last in good condition for several weeks, the sweet Lily-like fragrance which the blooms possess rendering them additionally attractive, and a single specimen upon the stages of an Orchid house will fill the whole structure with perfume.

This species was one of those known to Du Petit Thouars in 1822, but it was about thirty-four years later when living plants were first brought to England by the Rev. W. Ellis, who found it in 1854 growing on the branches of trees on the margins of forests in the low and hot districts of Madagascar. A few years later a plant produced flowers at that traveller's residence, Hoddesden, when the plant attracted much attention owing to the peculiarity of its structure. Since that time it has been generally distributed; and on December the 10th, 1861, Messrs. Veitch & Sons exhibited a specimen at a meeting of the Royal Horticultural Society, when a first-class certificate was awarded for it. As regards the structure of this Orchid the chief peculiarity is the extremely long spur, which, though rarely exceeding a foot in length in cultivation, is said to attain 1½ foot in its native habitats, and from that character the specific name is derived.

Another of the strong-growing forms is *A. eburneum*, but not so remarkable as the one just described, though from its free-flowering habit it is one of useful *Angræcums*, especially as the flowers are produced at a time when the Orchid house is comparatively dull—namely, from December to February. Grown in pots excellent results are obtained, and several unusually fine specimens in some of the chief London nurseries, Kew, and elsewhere have been noted in this Journal at various times. The plant is of robust habit with long leaves arranged in a similar manner to those of *A. sesquipedale*, and it bears numerous erect spikes or racemes of large flowers, of which the roundish pure white lip forms the most conspicuous portion, the sepals and petals being narrow and of a greenish tint. Two varieties are known—one named *virens*, which has smaller and less handsome flowers than the species, but is rather more graceful in habit. Another, named *superbum*, is decidedly superior to the type in the size of the flowers, and is said to be one of the introductions of the Rev. W. Ellis.

The type is native of Madagascar, where it was found by Mr. Forbes a few years previous to 1830. It was also found in the Isle of Bourbon by another traveller. Specimens were introduced to the Horticultural Society's Gardens, where one flowered in November, 1831, from which a figure was prepared for the "Botanical Register," where it is stated that it was believed the specimen was the only one in the country. Twenty years later a much better figure was published in the "Botanical Magazine," prepared from a plant at Kew which had been received from Mr. Clowes.

One of the most useful is *A. citratum* which flowers freely, producing elegant pendulous racemes frequently a foot in length, with closely packed small creamy white or pale yellow flowers, which are nearly an inch in diameter, with spurs about 1½ inch long. The colour is very delicate, and it is to that the term "*citratum*" refers, and not to the possession of any marked fragrance as some have supposed. It is a charming little Orchid, and when suspended from the roof of an Orchid house its arching racemes are seen to the best advantage in contrast with the deep green foliage of the plant, and the rich colour of some *Dendrobies*, the glowing little *Sophrontis*, and the showy *Ada aurantiaca*.

Though *A. citratum* has not been many years in cultivation it was known to Du Petit Thouars, who described it in the work already referred to. It is a native of Madagascar, whence Messrs. Veitch obtained it nearly twenty years ago, and in their nursery it first flowered in March, 1865. In the following year a specimen was exhibited at Kensington by the same firm in a class for new Orchids shown in flower for the first time, when a prize was awarded for it. In 1867 a very good coloured engraving of it appeared in the "Botanical Magazine," and on February the 18th, 1874, the Floral Committee of the Royal Horticultural Society awarded a first-class certificate for the plant. It unquestionably merits a place wherever elegant Orchids are appreciated, and has now become a familiar occupant of collections.

Angræcum Kotschyi is another of the beautiful Orchids which Messrs. Veitch & Sons have brought into notice, and for which they obtained the award of a first-class certificate at the meeting of the Royal Horticultural Society, October 12th, 1880. It not only possesses sufficient attractions to render it a

worthy companion for the best of its genus, but the peculiarity of its structure is additionally interesting, and on the occasion named the plant exhibited received much attention. Like its allies, it is epiphytal in habit, being found on trees near Zanzibar. The shining green leaves are rather short and broad; the creamy white flowers being 1 to 1½ inch across, and produced in pendulous racemes about a foot long. Each of the flowers is furnished with a reddish-tinted spur 6 or 7 inches in length; but, unlike all other *Angræcums*, it is curiously twisted somewhat in the manner of tendrils. This is the peculiar part of the plant's structure, and has given rise to several opinions as to its probable utility to the plant. The Rev. G. Henslow, when describing the plants exhibited on the occasion named, referred to it, and hinted

and habit, being less strong in growth than *A. eburneum*, and more robust than *A. Kotschyi* or *A. falcatum*; but it thrives very well in a basket, and may even be grown upon a block, though the former system of culture is generally the more satisfactory. The plant is rather compact, with dark green moderately broad leaves, two-lobed at the apex, and arranged in a distichous manner. The flowers are about 1½ inch in diameter, white with a tinge of rose, each having a spur 2 inches in length; they are borne in long pendulous racemes, and possess a slight fragrance. Specimens were found by Mr. Bowdich when travelling in West Africa near Cape Coast Castle, and from his widow Messrs. Loddiges obtained plants more than forty years ago, thus first introducing it into English and probably to European gardens.

FIG. 35.—ANGRÆCUM CHAILLUNUM.

at the possibility of the spurs not only resembling tendrils in appearance but in function also, and that they may possess a certain sensitiveness which would enable them to twine round contiguous objects, thus supporting the rather heavy inflorescence. The surmise appears very reasonable, but further observations are required to substantiate it.

The plant is named in honour of Theodor Kotschy, who found it a year or two previous to 1840, and it has been since discovered by several other travellers. Some of the most recent that have been introduced were, I am informed, originally sent by Dr. Kirk to Gerald Waller, Esq.

A. bilobum is included in most of the large trade collections of Orchids, and occasionally seen in gardens where those plants receive more than ordinary attention. It is intermediate in vigour

It was a matter for surprise to some that *A. Chailluanum* should have been awarded a certificate at the meeting of the Royal Horticultural Society's Orchid Committee meeting on the 27th ult.; not because the plant is wanting in attractions, but because it has been known in this country for about twenty-three years, and cannot therefore be regarded as a new plant. There was a rule at one time to the effect that certificates would only be awarded for novelties, but difficulties cropped up at various times, when old but scarce plants were brought into notice, and it was considered advisable to make awards for such that possess undoubted merit. In this way *Angraecum Chailluanum*, though not particularly rare at the present time, was thought worthy of some recognition, and the exhibitor of a well-grown plant (Mr. Tautz, Studley House, Hammersmith) was accorded a first-class certificate, and is represented in the illustration (fig. 35).

The species was found in Western Africa in the Gaboon region by M. du Chaillu, and a plant sent by him to Kew first flowered in May, 1866. It is of comparatively small growth, with slender stems rarely exceeding a foot in height, the leaves 4 to 6 inches long and half an inch broad. The flowers are white, with long, tapering, acute, recurving sepals and petals, and the yellowish spurs are 4 or 5 inches long. The racemes are loose and drooping. This *Angræcum* requires the temperature of the East Indian or Cattleya house, and succeeds either in a basket or pot.—L. C.

THE LOWFIELD NURSERIES.

CRAWLEY was a famous place in the old coaching days—a busy Sussex town, the stabling and courtyards of the old inns being five times more extensive than required by present day demands. It was one of the chief resting places—the half-way house, so to say, on the turnpike road between London and Brighton. Like many other towns to which coaching once gave life, Crawley steadily collapsed into sleepiness as the coaches gave up the contest with railways. Little or nothing was heard about the place for years beyond the immediate neighbourhood, but there appears to be some revival of ancient habits amongst persons of leisure, and coaches are now on the road again between the metropolis and the queen of southern seaside resorts. Crawley, with its slow-sounding name, may once more resume activity, and if it had many such enterprising inhabitants as the Brothers Cheal it certainly would do so, whether coaches ran or not. These active, diligent men belong to the railway age, and in a very few years have made the name of their native place familiar in the horticultural world.

The Lowfield Nurseries are about two miles from the town, and the railway station is in it. It looks like the main street siding, and would be open to it but for the level crossing gates. Most persons, however, travelling from London find the Three Bridges Station, on the main Brighton line, more convenient. It is three miles from the nurseries, but if Mr. Joseph Cheal happen to meet a friend at the station he will run him over the ground at the rate of seventeen miles an hour with his favourite home-raised and home-trained trotter. The animal is like its master, very quiet, yet very much alive when business has to be done.

It sounds almost incredible when we are told that the ground occupied by the nurseries and comfortable homestead was a ploughed field nineteen years ago; but the Cheals are not boasting men, and would not say what is not true. The land on which the buildings stand and several acres surrounding was bought by Mr. Cheal, senior, the parent of the thrifty sons, who was a well-to-do farmer, and had a good local seed business. The "old man is yet alive," hale and active, in his ninetieth year. He has built himself a span-roofed house for growing Cucumbers and Tomatoes in future, for he must have something to do—some source of enjoyment and pleasure, some "work," and the good crop of the present year is the work of his own hands. Diligence in business with temperance in habits have made him what he is and the business what it is to-day. The nursery grew out of the seed trade, and its extent is now, after a recent addition, eighty-five acres. Probably sixty and possibly more are occupied with fruit trees, Roses, Dahlias, Conifers, evergreens, ornamental trees, and herbaceous plants; indeed, whatever is found to be required in the way of trade.

The time appears to have been well chosen for establishing this business in Sussex, for several small nurseries in different towns were waning, the trade simply dwindling away through the old habit of waiting for customers. Messrs. Cheal, no doubt observing the results of lethargy of that nature, determined to adopt a different course—lay a good foundation, provide articles on which they could pledge their name, then let the world know they had them by the same fair business methods that other successful men have adopted. They first then secured a good home trade, and for this the district was favourable. It is salubrious, in some parts highly picturesque, and being within easy reach of the metropolis attracted rich London merchants and others to acquire residences and add thereto parks and gardens. Then the business was extended and made general, the proprietors entering fully and fairly in the competition of the world.

The time for commencing when they did appears also to have been favourable in another important respect, for it just enabled them to get well established, and their grounds well stocked with saleable goods when a revival set in on the subject of fruit growing, and a greatly increased demand arose for trees. The importance of fruit as food became to a larger extent recognised, and the desirability of growing much more at home, instead of purchasing from abroad, at length was admitted. This extra demand gave the opportunity for the firm to step to the front as caterers, and it is no doubt a fact that the trade of the older firms has increased with the advance of the new. The increase of some is known to be considerable, and if there should be a decrease in any the reason is not far to seek.

The soil of the Lowfield Nurseries may be described as a good holding loam, not easy to work when wet, while it bakes when dry, but catch it right and it falls like powder. It seems to suit everything, or is made to do so, with such additions as experience has found the most suitable. Rhododendrons grow as well and compactly, setting their buds as freely as in the best of sandy peat, and a great deal better than in much soil that is so described. It is the same with all kinds of American plants and Conifers, which, whether green or variegated, are in the best of colour, while fruit trees, Roses, and Dahlias evidently find

what is requisite for their healthful growth. Early in the month the last named flowers made an imposing display, as may be imagined when it is stated they are grown by the acre. There were really several acres, the singles being kept distant from the others, and thousands of varieties of these were flowering for the first time; but so good are the named varieties now that only few can be selected as likely to win certificates or awards of merit, for being distinct from and superior to others in cultivation. Still, such awards are obtained, as has been the case this year both at the National Dahlia Show and the Royal Horticultural Society. Messrs. Cheal took the single Dahlias in hand in their early days, and by care in cross-fertilisation became the originators of many beautiful varieties. All the other types are extensively grown also, and a few good new forms have been raised. One, a pleasure ground and border variety, was, as such, chosen for further trial, and appropriately named Profusion. It is nearly as free as Glare of the Garden, but of more rounded bush-like habit, with medium-sized purplish magenta flowers. It is highly effective, admirably adapted for the purpose indicated, and for affording flowers for cutting by the armful.

By far the greater extent of the nursery is devoted to fruit trees of various forms and sizes, trained and untrained, and in all the leading varieties. There are 250,000 of them, and 45,000 just budded for succession. From the commencement a speciality was made of cordon trees, and of these there are thousands studded with fruit buds of the varieties that are the most likely to give satisfaction to planters. They are adapted to small gardens and large, and the large sales prove their popularity. Walls and fences can be covered by them more quickly than any others, and they are the easiest of trees to manage. There are acres of vacant fences and buildings yet to be covered in various parts of the country, and where these do not exist it is easy to stretch a few wires for supporting the trees. There are examples of fences in the nurseries, and of arches over walks covered with fruit-bearing trees, and photographic representations appear in the catalogue of the firm.

Standard, half-standard, dwarf and trained trees of the different kinds and in great, perhaps too great, variety, are grown in "drifts," the number of each variety being in proportion to the demand, but the desire is to reduce the varieties, and "work" a greater number of those selected as the most certain bearers and serviceable. That is a change that most or all nurserymen would be glad to see effected, and purchasers of trees are gradually finding out they will equally benefit by it. But it is the same in buying trees as with anything else, most purchasers like to be choosers, and to obtain what they order; therefore, as long as certain varieties are asked for they will be grown, though others intrinsically better could be supplied at the same price.

Several of the small Apple trees were bearing handsome fruit, and the fruit room contained an interesting assortment. Of the newer varieties Bismarck is one of the largest and richest in colour, the trees bearing freely, and will be wanted in many gardens. Hornead's Pearmain was laden with well-shaped medium to large fruit, and is regarded by the firm as one of the most reliable and good for both culinary and dessert purposes. Professor is distinct among the early Codlin type. In shape it is not unlike Manks Codlin, but larger, and instead of being pale is golden yellow, which gives it a very rich appearance. The Queen is bearing heavily on small trees, the fruit being large and handsome, and regarded by Messrs. Cheal as one of the most profitable to grow. Pott's Seedling, Lane's Prince Albert, Ecklinville, Frogmore Prolific, Domino, Bramley's Seedling, and Wellington are in great demand for their usefulness as culinary sorts, with Red Astrachan and Duchess of Oldenburg for both cooking and dessert. As dessert sorts there is a run on Claygate Pearmain, Cox's Orange Pippin, King of the Pippins, Mannington's Pearmain, and Worcester Pearmain for general utility, and it is expected that Lady Sudeley, or Jacob's Strawberry, will be in equally great demand when its merits are better known. Large stocks have to be maintained of Blenheim Orange if it is slow in bearing, New Hawthornden, Lord Grosvenor and Suffield, Yorkshire Beauty (Greenup's Pippin or Counsellor), Peasgood's Nonesuch and Ribston Pippin; and it will be conceded that those who plant the varieties named are not bad judges of Apples. It would not do, however, to go into Sussex and omit mention of what may be termed the Apple of the county, the Forge. It is the heaviest and most constant bearer of all, every tree being laden with orange red fruit, only medium sized, however, and probably too small for market purposes generally. Messrs. Cheal do not "push" it, but simply state its merits in Sussex, leaving others to try it elsewhere if they wish to do so. It needs no recommending in the county where it is known so well.

Of Pears, Plums, Cherries, Peaches, Nectarines, and Apricots it can only be said they are fully represented, and like the others in as clean and healthy a state as could be desired. A new orchard house has been erected, and it is intended to cover the roof mainly with cordon Pears. At present there are besides those planted out Pears and Apples in pots bearing very large fruit, and a house is devoted to Vines in pots.

There are well appointed offices, and in them admirably executed landscape plans by Mr. J. Cheal, who has a talent in that line, and as a consequence is entrusted with the laying out and remodelling of parks and gardens in various parts of the country, and being as well skilled in photography he can show specimens of his work. He is also able to show four splendid and costly volumes of the "History of Surrey," with an inscription from the gentleman who presented them as testimony of his appreciation of the manner in which the recipient had completed the work of laying out and planting a large garden with which he was entrusted.

Messrs. J. & A. Cheal are straightforward men of business, and it

is pleasurable to spend an hour or two with them in their extensive and well appointed establishment.—J.

NATURALLY GROWN CHRYSANTHEMUMS.

TREATMENT OF PLANTS GROWN FOR THE PRODUCTION OF EXHIBITION BLOOMS A SHORT TIME PREVIOUS TO THE SHOWS.

[By J. Doughty, Angley Park, Cranbrook. Read at the National Chrysanthemum Society's Conference, September 11th, 1889.]

IN consequence of the varying conditions under which Chrysanthemums are grown owing to the difference in the practice of cultivators and in the climatic conditions of districts, it is somewhat difficult in referring to the treatment naturally grown plants for the production of exhibition blooms should receive to fix upon a starting point. Much, as the majority of you are aware, depends upon the strength of the plants, the firmness of the wood, and the treatment they have hitherto received.

Speaking as a southern grower, we will suppose that the plants have been well cultivated and are now strong and healthy. We will also assume that the wood is well solidified, and that they have their buds in various stages of development. At the outset I will call your attention to a matter of the greatest importance, and that is the application of a rich top dressing. We top-dress our plants at the end of July or early in August, a space of about 2 inches being left at the final potting for this purpose. About an inch of the material to be used is placed upon the surface of the pots and pressed down rather firmly, the application being made when the soil in the pots is moderately dry, so that it does not work into a paste. The mixture used for top-dressing consists of one part of loam, one part of decayed manure, a small quantity of old mortar, and a sprinkling of bone-meal. For some time afterwards the plants are watered with a can, to which a rose is affixed to avoid the risk of the top dressing being washed out of its place, or, indeed, being greatly disturbed. Whatever feeding the plants may have had previous to this surface dressing should be continued afterwards, as the top dressing has no immediate effect unless a fertiliser of quick action be added to it. But the addition of manure that will act rapidly I do not think absolutely necessary, although I used it previous to last year. Now if the surface material be examined about three or four weeks after its application, strong healthy roots will be found working their way through it, and when the time arrives for housing the plants the surface will be seen to be more or less covered with these healthy, vigorous feeders. In my opinion nothing can be of greater assistance in the taking up of supplies of food so essential to the plants during the development of the buds than these newly formed fibrous roots. This may at first appear to have but little bearing upon the future treatment of the plants. I have, however, explained this to show the condition the plants must be in as regards root action. Having, then, secured plenty of newly formed rootlets for the taking up of the food, we now feed chiefly with Clay's fertiliser and Thomson's Vine manure. These we use alternately, at intervals of about eight days, but in this matter we are guided by the state of the weather. If prolonged dull wet weather sets in the manures must be used more sparingly, so as not to cause too quick a growth, or the flower stems will be weak and the blooms lacking in substance. We use both manures at the rate of about 1 oz. to each plant of the strongest growing varieties, such as Fair Maid of Guernsey, Grandiflorum, Maiden's Blush, Princess of Wales and its sports, and the Queen family. The latter I consider the greatest feeders of all. In the case of weaker growing varieties, such as Meg Merrilies, Criterion, Jeanne Délaux, Lady Hardinge, and Mrs. W. Shipman, we use the manure more sparingly, about three-quarters of an ounce to each plant being a very suitable quantity.

This rate of feeding is continued after the formation of the flower buds, with an occasional watering with liquid manure from the cesspool, as an occasional change of food is, I believe, very beneficial to them. The water used is previously placed in a large tub standing in the open, fully exposed to atmospheric influences; hence it is maintained at a somewhat similar temperature to that of the soil about the roots. As a still further assistance to the plants a bag containing soot is placed in this tub. This bag is refilled with soot about once a fortnight, as the goodness is found to be washed out of the soot in about that period. The plants are fed in this way until the blooms commence to expand, when all feeding ceases, excepting when the bloom is late. Then a little sulphate of ammonia is applied. But I do not advise the use of the sulphate excepting for the purpose of assisting in bringing forward late varieties, as it tends to shorten the durability of the blooms after their expansion.

Mildew is a most troublesome disease, and generally makes its appearance with us early in September. Sometimes it attacks the plants earlier, and this season they were attacked at the end of August. We are situated in a low-lying spot, and consequently the Chrysanthemums

are more subject to its attacks than are those grown in gardens occupying a higher and drier situation. On its first appearance every plant is dusted with flowers of sulphur, usually early in the morning when the leaves are wet with dew, as the sulphur will then adhere to the under surface. This is a very important point, as the rain cannot remove it from the under surface as it does from the upper surface. We seldom have to repeat its application, and I have not on any occasion since adopting this practice been troubled with mildew after housing the plants. Black fly is very troublesome with us every season about this time. To eradicate this pest we dust with tobacco powder immediately it makes its appearance. Also after the plants are housed and before the blooms commence expanding we fumigate slightly two or three times to free the plants from aphids that may remain.

Much depends upon the time the plants are housed, especially the late varieties. As to the time of flowering I do not care so much whether such varieties as Boule d'Or or Grandiflorum and the like, form their buds early in August or at the end of the month. Their blooms can be expanded by the middle of November. Last season I took Boule d'Or buds on September 1st, and Grandiflorum buds on September 8th, and exhibited them both in good form on November 12th. These, with such varieties as Princess of Teck and its sports, Barbara, and Thunberg, should be housed earlier, and placed in a favourable position. The above varieties, with others correspondingly late, are placed on the side stages of the greenhouse immediately over the hot-water pipes, and by means of large flower pots are raised as near to the glass as possible. These receive a little sulphate of ammonia twice a week, and when the solar influences are not favourable a little artificial heat must be applied. The cultivator must use his own judgment as to the time of housing his plants, taking into consideration the locality in which he resides and the state of the buds (whether late or early), and also what means at his command for coaching them. These are important points which will repay a little study, and certainly cannot be ignored by those who would achieve success in a close competition.

Having stated how our late varieties are treated, I will allude to the general collection. The earliest varieties, which require very little fire heat—i.e., only sufficient to maintain a dry atmosphere, are placed in an earlyinery; and those that are naturally a little later are arranged upon the centre stage of the greenhouse. All are raised as near to the glass as possible by means of planks laid upon drain pipes placed in an upright position upon the stage. The plants are placed upon the platform thus provided, the tallest plants being arranged at the back and the dwarf ones towards the front. The plants nearest the front are raised by means of various sized flower pots, so that when all is complete they form a very sharp slope to the south. By this arrangement the upper growth of every plant receives a full share of light and air—a matter of great importance if good blooms are expected. Again, every bud can be seen when the cultivator is standing in front of them, so that should they require attention a plant or two can easily be removed for that purpose.

I will not occupy your time in alluding to dressing the blooms, as most growers will have acquired that art from practice and from the directions so well given in Mr. Molyneux's eminently practical book. But, in conclusion, I should like to draw your attention to one further important point, and that is arranging the colours on the exhibition board. I have noticed scores of stands arranged with sometimes as many as four, and even six, blooms of a bronze or other dark shade placed together. This is not as it should be, for by a judicious intermingling of the light and dark shades of colour each bloom will add to the effect of its neighbour, and consequently to the attractions of the exhibition table. It may also make all the difference between a first or second place in a close competition.

NORTH VERSUS SOUTH.

MAY I venture to invite an expression of opinion from Chrysanthemum growers upon the following suggestion? Could not a special class be provided in the Exhibition held in November at the Aquarium, with a duplicate class in the provincial Show in the north, as an equal test for northern and southern growers? Thus:—Say twenty-four incurved and twenty-four Japanese blooms (distinct) to be exhibited at both Shows, the one entry being sufficient for both Exhibitions. The class should be judged in the south, and points awarded; later on the same class, by the same exhibitors, should be judged by the same Judges in the north, and points awarded. The exhibitor obtaining the highest total number of points should then be the admitted national champion for that particular year, and the prize awarded. No greater test, in my opinion, could possibly be made of a grower's ability, not only to produce quality, but in timing his blooms.—JOHN DOUGHTY, Angley Park Gardens.

A PECULIAR CHRYSANTHEMUM BLOOM.

I ENCLOSE a bloom or rather bud of Chrysanthemum Lady Lawrence. I have four plants side by side, each plant with three buds on. The buds on two of the plants are in the same state as this; a third plant rather more backward is looking as though it may go off in the same eccentric manner, while the fourth, more backward still, looks all right.

I have no other variety with such a curious malformation; it therefore appears to me that Lady Lawrence is liable to it, and more especially the earlier buds. You will observe the stem has made a very long growth after the bud was fixed, and the leaflets on the side of the stem are peculiar.

I shall be glad if anyone can tell me the cause, or probable cause, of

the monstrosity, as I do not remember having met with a similar form before. Madame B. Rendatler sometimes forms a number of eyes, but I have not seen it like this.—R. F. JAMESON.

[The bloom sent has the outer florets extended into growths around the centre axis somewhat in the way of the Hen and Chicken Daisy and other flowers. It is probably due to the formation of a hard end and some check, the growths resulting from an effort of the plant to extend.]

A VISIT TO THE BULB FARMS OF HOLLAND.

[A paper read before the Nottinghamshire Horticultural Society by Mr. Alfred H. Pearson.]

IN these days of steam there is but little difficulty in getting to the Netherlands. There are several routes open to the traveller, but supposing we choose to go *viâ* Queenborough and Flushing we can leave Nottingham at 3.17 in the afternoon, and arrive in Haarlem at 11.20 next morning. One boat leaves Queenborough at 10 P.M., and if the sea be calm or you are fortunate enough to be a good sailor (which I am not) you can have a refreshing sleep, and be ready to get up and look about you when the boat reaches Flushing at 6 A.M. Having landed and passed the customs, we go into the waiting room to await the loading of the luggage and mails into the trains, and we have plenty of time to fortify ourselves with rolls and butter, eggs, and coffee. Once in the train we have a capital opportunity of seeing the country, for the track being slightly elevated and the land perfectly flat there is nothing to impede the view. But before we look out at the view let us look back a moment at the geographical picture. You will notice that I spoke of travelling to the Netherlands, which country most Englishmen insist on calling Holland. If you can imagine a Dutchman calling England Yorkshire you can just as well imagine what a Dutchman thinks of us when we call the Netherlands Holland. The Netherlands, as you know, consists of eleven provinces, of which North and South Holland are the the home of bulb-growing, and hence I suppose the English idea of calling the whole country Holland.

We have left our train standing at Flushing, which is on the Island of Walcheren, celebrated for growing the Cauliflower, which bears its name. From this island we pass into South Beveland, and thence into North Brabant, where at Rozendale the line branches, part going on to Cologne, Berlin, Hanover, and St. Petersburg, and the other branch crossing, by a very long bridge, one of the mouths of the Rhine, and entering, *viâ* Dordrecht and Rotterdam, into South Holland. Up to this point the land has been principally cultivated in small fields of two or three acres, and mainly by the spade, the crops being those usual on a farm, and also Broad Beans, Turnips, Onions, &c., &c., for seed. At Dordrecht we seem to have reached the paradise of allotment gardeners, for as far as the eye can reach in every direction nothing else is to be seen. Apples, Pears, Gooseberries, and immense quantities of Strawberries are sent from here into our markets. Leaving Dordrecht, we are soon at Rotterdam, and then the eye rests on one huge plain of grass, which, broken by ditches and here and there by trees, stretches right away through South and North Holland to Amsterdam.

What strikes us most in passing through this stretch of country is the great neatness and order of everything. Nothing seems to be wasted, and we do not see a yard of land unoccupied. The roads are well kept. They are generally paved in the centre with very small thin bricks set edgewise and macadamised on each side, and as the canals take all the heavy traffic they wear well. They are planted on each side with avenues of trees, the shade of which must be extremely grateful in the hot weather. The trees are all trained with perfectly straight stems, and being trimmed up to one height remind one of the trees we used to have in our German toy boxes years ago. They are certainly more neat than artistic, and yet they seem to be quite in harmony with everything else in the landscape. Another thing which much struck me the first time I visited the Netherlands was to see the cattle during the early part of the season turned into the fields with rugs on just as we treat horses. I thought that English farmers might learn a lesson here, for what can be worse than to take a sensitive animal like a cow, which has been shut up in a warm stable for four or five months, and turn it out into a grass field exposed to an east wind without protection? But I must not give any other details of the route, but hasten on to the bulb grounds.

The bulb farms are situated on a strip of land running close behind the sand downs from Leyden in South Holland to Alkmaar in North Holland, a distance of perhaps thirty-five miles, although the greater part of the farms are situated on the southernmost twenty miles—viz., from Leyden to Haarlem. This line is by no means direct, although it runs about parallel to the coast line, nor is all the land of equal quality. If it were we should not find the bulb growers giving £500 per acre for their best land. In some parishes a large proportion of the land grows bulbs, some have only a few fields which are capable of their culture, whilst perhaps the next parish on the line does not grow bulbs at all. One parish grows Hyacinths to perfection; another, where the land is stronger Tulips, whilst we find also from experience that certain varieties of each succeed best in certain localities.

In making this assertion as to varieties of Hyacinths doing better in one village than another, I shall come under the criticism of those who maintain that a good piece of Hyacinth land will grow all sorts equally well, yet I never see such Baron von Tuyl as I do in one village, nor such Queen of the Blues as grow alongside them, although other varieties on the same fields are no better and perhaps not even equal to those grown on other farms. Again, I know a spot where King of the Blues is grown in large masses, and superior in my judgment to

any grown elsewhere. And why should not this be so? Apples and Pears are wonderfully altered by the quality of the soil they are grown upon, although the climatic influences may be very similar. Take, for instance, Easter Beurré Pear, which is almost worthless at Chilwell, whilst at Elvaston Castle (eight miles away) it is grand; or Rivers' Prolific Plum, which produces an annual fortune at Sawbridgeworth, whilst in many places you can scarcely keep it alive.

What, then, constitutes good soil for Hyacinth culture? I can hardly tell you definitely, nor indeed can the growers, for they often have to experiment in order to find out if soil will do them well or not; but I can give you a few points. The best Hyacinth land is almost pure sand with a slight admixture of peat, and it is prepared in the following fashion. Of course most of the land has been used for bulb-growing for generations, and some for a hundred years or more, but in making a new garden the first thing is to level the land. This is done not by simply throwing the high parts on to the low, but by lowering the whole surface until it is about 2½ feet above the water line in the ditches. The land is then trenched to a depth of 6 or 7 feet (the men at the bottom of the trench being below the surface of the land). If there be any beds of peat they are taken out, as they prevent the drainage of the water downwards in the winter, and also arrest the rise of the water upwards in the summer, and without this the bulbs would be shrivelled up by a week or so of hot weather. Having taken out the peat as far as is necessary, the deficiency is made up with pure sand and the trenching mixes all together. The cost of this operation varies of course with the amount of surface soil to be removed and the peat to be taken out. In some cases they get the surplus sand off and sell it for ballast to the boatmen for as much as the labour costs. The peat is given away to the farmers for top-dressing grass land. In other cases they are not so fortunate. A friend of mine showed me fifteen acres planted last year for the first time, which the year before was covered with coppice wood, and it had taken 100 men six months of daily work to get it ready.

The land being levelled and trenched is ready for cropping, and we may look upon it in the same light as old bulb ground which has the following rotation:—First year, trenched 3 or 4 feet deep (sometimes 6 for a change), and manured. The manure is cow dung, and is applied in enormous quantities (about 6 inches thick by the best growers), and placed below the first spit of soil. In this land Potatoes are planted—"to take the fire out of the dung," as they say—and in digging up the Potatoes the manure becomes well incorporated with the soil. Second year Hyacinths are grown. Third year, Tulips or Ranunculus, Anemones, Gladioli, Narcissi, &c. Of course different growers have different ways. Some manure every third year, some only once in four years; some grow Hyacinths followed by Tulips, others grow Tulips followed by Crocuses. But where does this immense quantity of manure come from seeing that the pastures look so green? Ah! that's where the water carriage of this wonderful country comes in, for not a ton of the manure which is used on the bulb farms is made in the locality. Most of it comes from the other end of North Holland, between Alkmaar and the Hilder, and some comes from Friesland on the other side of the Zuyder Zee. "Well," I asked, "how do they go on there without manure? The farmers there can no more do without it than those can who live near the bulb fields." "True, but they occupy cooler land, to which cow dung is less suitable than to the sand land around the bulb farms, and so they bring the cow dung down in boats, and load back with horse dung and refuse grains, &c., from the gin distilleries at Schiedam." "And what becomes of all the Potatoes?" "They are sold by auction, and mostly come to England." I had my doubts as to what the quality of these Potatoes would be grown with so much raw manure. The land then is manured at a cost of from £30 to £50 per acre (exclusive of the trenching). We must now glance at the crop which is to be put upon it, and first in importance comes the Hyacinth.

HYACINTHS.

The Hyacinth has been cultivated in Holland for upwards of three centuries. Pages and even books have been written on its ancient history; suffice it to say that when all has been written but little has been proved, but it is generally accepted that the plant came originally from the Levant, and that its habitat was in meadows, flooded in spring and dry in summer. Endless discussion has taken place with respect to its original colour, which was probably blue, and not unlike our own wild Wood Hyacinth. Of much more interest to me than all the discussions on this question was one of Segher's admirable flower pictures, in which was a representation of the Hyacinth as he saw it about the year 1600. Walking round the gallery in the Hague on the 28th of last April I was admiring a grand picture by Seghers, when my companion said, "Look at that *Narcissus triandrus albus*, fancy their growing that in 1600." He was struck by seeing a plant which is supposed to be of recent discovery and introduction faithfully portrayed in this old painting, whilst I was equally interested to note that the Hyacinths in this and other pictures by the same artist are all blue, with long thin spikes and small bells, dotted about at intervals of about 1½ to 2 inches, whereas the Tulips were as fine in 1600 as any grown now under the florist section. However, although I only saw blue Hyacinths in Segher's pictures, it is known that white ones were grown in 1582, and in 1767 there were six yellow varieties catalogued. In 1734 one bulb of the old double Non Plus Ultra was sold for £133 8s. 6d., so we see that Tulips did not secure all the fancy prices in those days.

The Hyacinth is increased by four different methods. First, the

natural one of throwing off side bulbs or offsets; second, by hollowing; third, by crossing; and fourth, by seed. The first or natural method is not much used, because it is too slow, the second and third being improved methods whereby Nature is assisted. Some varieties succeed best from hollowing, whilst crossing suits others. The hollowed bulbs give a great number of small offsets, the crossed fewer and larger, which, as a rule, take one year less to come to perfection. I say, as a rule, for different varieties vary. Some of the hardy blues are ready for sale at four years old, whilst others are five or six years before they are fit to send out as first size bulbs. The bulbs sold as first size should be at perfection the following spring—i.e., when we have them. We very rarely see any bulbs on the fields flowering in their best form, for naturally when our friends have been at a great expense in growing them they like to reap the reward of their labours by turning them into cash, and as a proof that the demand is equal to the supply, we have the fact that very few bulbs are ever left over for planting. A few are used every year for propagating, but the bulk are sold. Occasionally we do see a bed of bulbs planted which should have been exported the previous year, and then the owner will point to them with pardonable pride and say, "There, your bulbs should be like that." The bulbs I saw were not the selected best bulbs, but the leavings of what came here, yet I feel sure that none of their exported brethren ever came up to the glorious blooms I saw on the field. It is a disgrace to our culture when it happens, as it occasionally does, that the second size bulbs planted in the open for beds produce infinitely superior blooms to the first size bulbs grown in pots for exhibition.

But I must go on to the fourth method of propagation—viz., by seed; this is only done in order to obtain new varieties. So far as I have seen no effort is made at artificial crossing; they simply plant a bed of good varieties mixed together, and allow Nature to take her course. Indeed many Dutch florists, Heer de Graff, the noted Narcissus raiser in particular, are rather jocular on the subject of cross-fertilisation, and say that they have obtained better results without it than we have with it. That may be; they started first in the race, and have climate in their favour. There is nothing peculiar about the propagation of Tulips, which is done by dividing the offsets from strong bulbs. Some varieties produce these offsets much more freely than others, and this is the reason that some very beautiful Tulips are kept for years at such a price as prevents their becoming general favourites.

Time will not admit of my going further into the question of propagation. I think, then, we may leave the details and for a moment take a view of the fields. What do they look like? It would be difficult to say. Each year they strike us with a different aspect, and in this case familiarity does not breed contempt. The aspect of the fields varies greatly; if you approach the border of a village where almost every labourer grows a few bulbs you will see in one small garden little patches of every colour, one little bed of yellow Tulips, one little bed of scarlet, half a bed of Robert Steiger, half a bed of Chas. Dickens, and a bed of a dozen sorts mixed. Walk a little further, and you come to the land of a large grower; you see beds of Hyacinths 10 yards long and 3 feet wide, divided by tiny sunk walks a foot wide, like Asparagus beds, so that in looking down the lines they seem like one bed; then you will see such a blaze of colour as you probably never saw before. It is wonderful! how the colours contrast! snowy white and crimson, indigo blue and yellow, purple and flesh-colour, red and azure blue. It is like a gorgeous carpet which stretches over 15 or 20 acres. Occasionally where two or more bulb farms adjoin you may see 40 or 50 acres one blaze of colour. The full glory does not last long, for as soon as the blooms are well expanded the beds are carefully looked over for rogues, and then the men come, armed each with a small knife and a basket, and start six, eight, or ten in a row, to cut off the flowers. This is to prevent the bloom exhausting the bulbs, and also (a matter of great importance) to allow the foliage every facility to develop. The blooms are thrown away in heaps, or often spread on the surface of the soil over newly set Potatoes to prevent the sand being blown away into the ditches or on to the neighbouring property.

The same with the Tulips, they only bloom a day or two and then are cut off. So if you would see the fields at their best you should know which are the early spots, and run round these first and so on to the later. After a week of this sort of thing, from early morn until night, most people get rather tired, and indeed many men who go over on business will not face more than two days of it. If the weather is hot you have such a glare of colour constantly before the eye, such a sense of being "crowded up" with Hyacinth perfume, that even at night you seem to be still walking the fields and have a difficulty in sleeping; a change of occupation for a day is then a great relief, and such a change may be found in one of the fine picture galleries for which the country is famous.

(To be continued.)

ROYAL HORTICULTURAL SOCIETY.

SEPTEMBER 24TH, 25TH, AND 26TH.

THE VEGETABLE EXHIBITION AND CONFERENCE.

THE introductory remarks respecting this Show on page 259 will give an idea of its extent and importance, while in the following notes the principal exhibits and exhibitors are named, the decisions of the respective Committees of selection not being completed in time for publication in this issue. The first day at Chiswick was a most unfavourable one, rain falling heavily throughout the greater part of the

afternoon; but Wednesday proved fine, and the proceedings of the Conference were commenced at 2 P.M. The Exhibition is continued to-day (Thursday), and the Conference will be resumed at 2 P.M. the papers to be read being noted on page 266. The order of the classes in the schedule is followed as nearly as possible in the appended report.

GREEN VEGETABLES.

Cabbages.—There was a good display of Cabbages, over 70 feet of staging being occupied with the exhibits in the three classes, in which there were about twenty entries. Messrs. J. Veitch & Sons, Chelsea, had an extensive collection representing all sections, very notable being Early Etampes, Denning's Early, Chou de Burghley, Early York, Little Pixie, and Rosette Colewort amongst the smaller Cabbages, with Offenham and Early Flat White amongst the larger ones. Messrs. R. Veitch and Son of Exeter, Messrs. Vilmorin & Co., Paris; H. Hannan, Edinburgh; W. Poupart, Twickenham; J. Carter & Co.; Oakshott and Millard also exhibited some of their special varieties and strains. Mr. J. Hughes, Bracknell; Mr. J. Willard, Highgate; and Mr. W. Pope, Highclere Gardens, Newbury, also showed samples of garden Cabbages.

Kales.—Considerable space was occupied with Borecoles and Kales, Messrs. Veitch & Sons having a fine type of Curled Kale in Extra Dwarf Curled. Mr. H. Deverill also had a good sample in the new Curled Culzean Castle. Messrs. G. Bunyard & Co. had specimens of Cottager's Kale, and from Chelsea came some tall Kales, the plain leaved Chou de Milan and Tall Green Curled being noteworthy.

Savoy.—These did not form a very large display, but Mr. G. Wythes Syon House Gardens, Brentford, had a good collection of varieties, comprising Gilbert's Universal, Early Dwarf Ulm, and Drumhead. Messrs. Bunyard & Co., R. Veitch & Son, and J. Veitch & Sons, also had collections—Dwarf Green Curled, and Early Dwarf Ulm, Yellow, and Drumhead, and Very Early Paris being capitally represented.

Brussels Sprouts.—Few dishes of picked Sprouts were shown, these being Wroxton from Mr. Deverill, Sutton's Exhibition from Mr. J. Hughes, Selected from Messrs. R. Veitch & Son, Veitch's Exhibition from Mr. G. Wythes, and Reading Exhibition from Mr. W. Pope, all fairly good neat samples. Plants were staged in pots down the centre of one of the tables from Messrs. J. Veitch & Sons, this being an instructive exhibit, showing the habits of the respective varieties and their relative productiveness. Mr. G. Wythes and Mr. H. Hannan also had several plants shown in the same way.

Artichokes.—These formed a moderate display, the best samples being from Mr. J. Lambert, gardener to Col. Wingfield, Onslow Hall, Shrewsbury, Messrs. Oakshott & Millard, W. Poupart, G. Wythes, C. J. Waite, and J. Veitch & Sons, Green Globe and Purple Globe being the only distinct types, the others differing chiefly in size.

Spinach.—Eight exhibits comprised all the Spinach shown, Prickly or Winter Spinach and Round or Summer Spinach being the chief varieties shown, but Mr. R. Smith, gardener to Lady F. Fletcher, Kenward, Yalding, Maidenhall, had a dish of the very large Viroflay, from seed sown at the beginning of August. Mr. W. Poupart also had a basket of New Zealand Spinach.

Cauliflowers were well but not largely represented. There was only one class. Veitch's Autumn Giant was best represented, the majority of the exhibitors showing this grand variety, and few of the heads were coarse. Pearl and Walcheren were also shown. Amongst the Broccolis were Michaelmas White and Veitch's Self-Protecting. Mr. R. Smith, Maidstone; Mr. Hughes, Bracknell; Mr. J. Lambert, Shrewsbury; and Mr. W. Wildsmith, Heckfield, were amongst those who showed, the list including several already named.

Red Cabbage.—Two examples of one variety were asked for, and they were shown by eleven exhibitors. The varieties represented were Large Blood Red, Red Dutch, Sutton's Blood Red, and Red Drumhead, Messrs. Bunyard, Chadwick, Wildsmith, Oakshott & Millard, Smith, J. Millard, J. L. Ensor, J. Hughes, J. Carter & Co., and J. Dobbie & Co. showing them.

FRUITS AND PULSE.

Tomatoes.—Quite an ornamental display was formed by the Tomatoes, of which a good number was shown by Messrs. Veitch & Sons, Vilmorin and Co., Oakshott & Millard, C. J. Waite, T. Laxton, Harrison & Son, W. Poupart, T. Lockie, Windsor, and G. Bunyard & Co. Fine samples of fruits were shown under the following names:—Mikado, Golden Queen, President Cleveland, Perfection, Ham Green Favourite, Hackwood Park, Dedham Favourite, and Waite's Seedling.

Gourds.—An extensive and varied exhibit of Gourds occupied a table the whole length of theinery. Mr. C. Osman, Sutton, Surrey, had a very large collection, comprising about forty varieties, varied in form and colours. An excellent collection was also contributed from the Society's garden, comprising some very peculiar and interesting forms. Messrs. R. Veitch & Son, J. Veitch & Sons, G. Bunyard & Co., and Harrison and Sons were also exhibitors. Huge specimen Gourds, Pumpkins, and Vegetable Marrows were shown by several exhibitors.

Beans.—Runner Beans were represented by some well-grown collections. The most notable varieties were Girtford Giant, Chelsea Giant, Carter's Jubilee Runner, Ne Plus Ultra, Neal's Runner, Veitch's Mammoth, and The Czar. Messrs. J. Carter & Co., H. Deverill, J. Veitch and Sons, J. Wallis, Keele Hall Gardens; C. J. Waite, Harrison & Sons, W. Palmer, and J. Lambert were the chief exhibitors.

Dwarf Beans.—These were scarcely less well represented than the Runners, but they were not numerous. Canadian Wonder, Ne Plus Ultra, Negro Longpod, Mohawk and Syon House were the chief varieties

from Messrs. Harrison & Son, G. Wythes, J. Willard, J. Wallis, J. Hughes, and C. J. Waite.

Peas.—The exhibits in these classes were more numerous than might have been expected, both dishes and varieties being abundant. Messrs. J. Waite, Goodacre, Bunyard & Co., Divers, Maher, Oakshott and Millard, and J. Carter & Co. were the leading exhibitors.

Cucumbers.—Lockie's Perfection, Carter's Model, and Purley Park were the chief varieties shown, Mr. Lockie's five fruits of his variety being excellent. Messrs. J. Carter & Co. had six large fruits as grown for seed. Messrs. Bunyard & Co. showed some ridge varieties, and Mr. Laxton had a variety named "Open Air," a ridge Cucumber raised from Telegraph crossed with the Bedfordshire Ridge, sown May 16th, and grown entirely of doors.

Capsicums and Chilies.—Messrs. Vilmorin & Co. were the chief exhibitors of this, showing Large Bell, Sweet Spanish Mammoth, Golden King, and Bull Nose, all large richly coloured varieties. Mr. J. Willard sent a dish of Cayenne Capsicums, and Mr. Divers Long Red Chilies.

TUBERS AND BULBS.

Potatoes.—A considerable portion of a table the whole length of the large vinery was filled with Potatoes, forming one of the most important parts of the Exhibition. The tubers shown were of satisfactory quality generally, and the varieties were of course very numerous. It is, however, unnecessary to refer to them at length now pending the Judges' report. From the Society's gardens came about fifty dishes. Messrs. Oakshott & Millard sent twenty-one dishes, Messrs. G. Bunyard & Co. had thirteen dishes, Messrs. Harrison & Sons fifteen dishes. In the class for twenty-five dishes Mr. J. L. Ensor, Ipswich; Mr. J. Hughes, gardener to Col. Cartwright, Eydon Hall Gardens, Byfield, Northampton; and Mr. E. Wiles, gardener to A. Cartwright, Esq., Edgcote, Banbury; and Mr. Lye, Cliffe Gardens, Market Lavington, were the chief exhibitors. From the Society's garden came a collection of American seedlings. Amongst other exhibitors were Messrs. R. Veitch & Son, Webb & Sons, Stourbridge; W. Palmer, Thames Ditton; Mr. Wildsmith, Heckfield Gardens, Winchfield; J. Burnett, Deepdene Gardens, and C. Sharpe & Co.

Onions.—These occupied about 70 feet of tabling, and were of excellent quality. One of the largest collections in class 44 was that from Mr. H. Deverill, Banbury, which consisted of thirty dishes. Such well-known varieties as the Banbury, Improved Reading, Blood Red, James' Keeping, Nuneham Park, Giant Rocca, White Lisbon, and White Spanish were shown well, and in addition were the fine newer varieties Rousham Park Hero, an excellent exhibition variety; Ailsa Craig, of which there were some fine bulbs; Cocoa Nut, Cranston's Excelsior, Anglo-Spanish, a handsome Onion, resembling Rousham Park Hero; and Improved Wroxton, the latter a globe-shaped variety of good appearance. Messrs. Vilmorin & Co., Paris, exhibited ten dishes, the bulbs being of large size and in beautiful condition. Giant Rocca was totally different from the variety under that name in other collections. The bulbs were of enormous size, 7 to 8 inches in diameter, and bright in colour. Flat Italian Tripoli and White Lisbon were also grandly shown, being large in size and white as milk; Giant Madeira (globe shaped) was very striking in appearance. Messrs. Oakshott & Millard, Reading, also had ten dishes, a very neat and even collection; Improved Reading, a very useful Onion, was well shown amongst them. Four dishes were shown by Mr. Wythes, Syon House Gardens, Brentford. A collection of thirty dishes came from Messrs. J. Veitch & Sons, Royal Exotic Nurseries, Chelsea, and it was chiefly interesting as showing many old and tried varieties in clean bright condition. Of the newer varieties Southport Red Globe was the most noteworthy; it is a medium-sized Onion of useful appearance. The Queen was shown in this collection about the size of marbles. As sometimes grown it is 3 to 4 inches across; which is the true variety? Messrs. Bunyard of Maidstone also exhibited six dishes in this class. There were six collections of six dishes. Mr. Deverill had a splendid lot, comprising Ailsa Craig, Rousham Park Hero, and Anglo-Spanish in very fine condition; Cocoa Nut, very large; The Black Douglas, a very dark skinned seedling, stated to have been raised at Culzean Castle, Ayrshire, by Mr. Murray; and the Improved Wroxton. These were remarkable as evidence of skill in culture applied to naturally large varieties. They had been grown in a deeply trenched stiff black loam on a south border, being raised from seed at the end of January, pricked out and grown with bottom heat until the middle of April, then planted out, mulched with cow manure, and dressed during the season with Cannell's manure. Mr. Pope, gardener to the Earl of Carnarvon, Highclere Castle, Berks, had a well-grown collection of bulbs, the varieties corresponding with those already named, except Improved Pinesfield, a remarkably handsome and solid Onion. Messrs. R. Veitch & Son, Exeter, showed old varieties very well, and Messrs. Wallis, gardener to R. Sneyd, Esq., Keele Hall, Newcastle, Staffs; W. G. Gilbert, Norfolk; and R. Nicholas, Castle Hill, North Devon, also exhibited. There were twenty-five single dishes, and it is quite impossible to name all the exhibitors. Moreover, the varieties were chiefly the same as those already named.

Kohl Rabi. green and purple varieties, came from Messrs. Osman, Sutton, J. Veitch & Sons, and Jas. Carter & Co., but these are not much used for culinary purposes in this country.

Turnips.—There were about twenty exhibitors of Turnips in the two classes provided for them. Veitch's Red Globe, Snowball, Dobbie's New Model, Green Round, Red American Stone, Golden Ball, Orange Jelly, White Dutch, and Early Milan were amongst the varieties best shown, and formed a very fine display. Messrs. Pope, Palmer, R. Veitch

and Son, Dobbie & Co., Wythes, Lambert, R. Maher, and Wallis showing some of the best produce.

Leeks were a very fine display. There were some fifteen exhibitors of them, and there was some splendid produce staged. The Lyon was finely shown, also Renton's Monarch, and Prizetaker, Musselburgh, and Ayton Castle were also noteworthy. Messrs. Carter exhibited good examples of Holborn Model, and Messrs. Deverill & Waite of Oxonian. Other exhibitors were Messrs. Dobbie, Wythes, Pope, Lambert, Harrison, Dunn, R. Veitch & Son, Oakshott & Millard, Stuart & Mein.

Jerusalem Artichokes, Shallots, and Garlic were not much shown.

TAP ROOTS.

Beetroot.—The exhibits occupied 50 to 60 feet, and were remarkably well shown. Of single varieties there were upwards of twenty exhibitors. Amongst the varieties best represented were Cheltenham Green Top, Hope's Middleton Park, Dobbie's New Purple, very dark flesh; Pragnell's Exhibition, a good variety both for kitchen and showing, well coloured, handsome in shape, and of good flavour; Sutton's Excelsior, Dell's Crimson, a useful garden Beet; some remarkably fine roots of that useful old variety Nutting's Red, McGregor's Favourite, and others, and among the exhibitors were Messrs. Veitch of Exeter; Mr. Taylor, Cheltenham; Mr. Wythes, Mr. W. G. Gilbert, Mr. Chadwick, Ealing; Messrs. Stuart & Mein, Kelso, and others. There was a good entry with collections of four varieties, these including those previously mentioned, also Eclipse Turnip-rooted, Carter's New Early Round, Webb's Extra Dark, Sutton's Improved Blood Red, and amongst the exhibitors were Messrs. Carter & Co., High Holborn, London; Messrs. Bunyard, Mr. C. J. Waite, Esher; Mr. Wallis, Mr. Malcolm Dunn, Dalkeith; Mr. Wythes, Messrs. Oakshott & Millard, Messrs. Vilmorin and Co., Messrs. Harrison & Son, Leicester; Mr. Palmer, Thames Ditton, and Messrs. J. Veitch & Sons, Chelsea.

Salsafy and Scorzoneria.—These were in capital condition, the latter especially, Messrs. Carter & Co. having some fine roots. Messrs. J. Veitch & Sons, Harrison & Sons, Willard, Oakshott & Millard, Bunyard, Gilbert, Burnett, Chettleburgh, and Smith, also had good produce.

Stachys tuberifera.—These came from Messrs. Carter & Co., who had plants in bearing and picked roots; J. Veitch & Sons; Dunn, Dalkeith; and J. Willard. Horseradish appeared to be shown only by Messrs. Veitch & Sons and W. Poupert, Twickenham, the latter having fine examples.

Parsnips.—Seventeen lots of these were shown, five roots each of one variety. Messrs. J. Veitch & Sons exhibited fine roots of Improved Hollow Crown; Messrs. Dobbie & Co. of their selected variety, and Messrs. Oakshott & Millard of Student. Mr. Wildsmith also showed the latter well, and Mr. Lambert had some good examples of Hollow Crown.

Carrots.—About twenty-five exhibited Carrots, and these were a splendid display; in fact, one of the best in the Exhibition. Sutton's Intermediate, Carter's Summer Favourite, Carter's Scarlet Perfection, Sutton's Early Gem, Veitch's Matchless, Veitch's Scarlet Model, Saint Valery, Early Shorthorn, Improved Altrincham, James's Intermediate, Long Surrey, Scarlet Horn, Early French Horn, Harrison's Early Market, and Nantes were all well represented, some of the best produce coming from Messrs. Vilmorin, Bunyard, J. Veitch & Sons, C. Sharpe and Sons, Harrison & Sons, Oakshott & Millard, R. Veitch & Sons, Chettleburgh, W. H. Divers, Lambert & Waite.

SALADINGS.

Celeriac.—Five lots of Celeriac were shown, much the finest being that from Messrs. Vilmorin & Co., very large roots of these varieties, Apple-shaped, Large Early Erfurt, and Large Smooth Prague. Mr. F. Taylor, Swindon Hall Gardens, Cheltenham, and Mr. J. Willard had specimens in this class, but much inferior to the others.

Celery.—About 40 feet length of staging was devoted to the Celery exhibits, which comprised some admirable specimens. Extremely large heavy sticks were shown by Messrs. Dobbie & Co., Rothesay, Invincible White and Select Red being the varieties. Mr. H. Deverill had good samples, named Aylesbury Prize Red. Mr. C. J. Waite showed Sulham Prize, Standard Bearer, and Aylesbury Prize Red in fine condition. Messrs. J. Veitch & Sons sent three stems of White Plume, grown in Scotland, the stems and part of the leaves white or variegated.

Lettuces.—A large and representative collection of these came from Messrs. J. Veitch & Sons, including all the principal types, Royal Albert, Californian Curled, Early Paris Market, Brown Dutch Neapolitan (very large), and Marvel being notable amongst the Cabbage varieties. Of Cos Lettuces, Brown Marseilles, Sutton's Queen, and Paris White were good.

Endives.—Messrs. J. Veitch & Sons, Oakshott & Millard, R. Maher, and G. Bunyard & Co., were the chief exhibitors of Endives, both round-leaved and curled being well shown. Moss Curled, Picpus, Stag's Horn, Imperial Curled, and The Garland were the best of the Curled types, white and round-leaved Batavian being notable in the other section. Messrs. Vilmorin & Co. contributed a collection of Endives in shallow pots, some of the samples being quite ornamental, especially one named "fine lacinated Louviers," very compact and dwarf. Mr. G. Wythes also had good specimens.

MISCELLANEOUS.

Cardoons.—Three exhibitors had specimens of Cardoons, all enormous stems, and leaves 4 or 5 feet long and 9 to 12 inches across at the

thickest part. Mr. J. Lambert, Mr. W. G. Gilbert, and J. Veitch and Sons were the exhibitors.

Leaf Beets.—The two exhibits of these filled but small space. Messrs. J. Carter & Co. had chiefly light-coloured varieties, such as Seakale, Silver (very fine), and Green or Spinach. Messrs. J. Veitch & Sons had the Silver Beet in good form, contrasting well with the dark red Chilian Beet.

Parsley.—Messrs. J. Carter & Co. had samples of Champion Moss Curled and Fern-leaved, very fine, with the Plain-leaved Hamburg. Messrs. G. Bunyard & Co. also had a good strain of Fern-leaved Parsley; Messrs. Dobbie & Co. showed a capital selected curled strain; Mr. W. Poupart had a useful form; Messrs. J. Veitch & Sons had a fine curled strain; and Mr. R. Dean showed Moss Green Curled, very compact and good.

New Vegetables.—Mr. J. Willard and Messrs. J. Veitch & Sons sent specimens of Asparagus Chicory, with long leaves, somewhat like the common Dandelion, but much longer, and with red midribs, the side shoots being cut and used for cooking. Mr. J. McIndoe, Hutton Hall Gardens, showed his new Sprout named Hutton Hall, referred to in the report of the Fruit Committee.

Miscellaneous.—Messrs. Vilmorin & Co., Paris, contributed an interesting collection of Radishes, representing nineteen distinct varieties, some of them remarkably so. Of long Radishes the best were Long White Vienna, Long Scarlet, White Hospital, White Olive, Half-long Scarlet, Purple Olive, and Scarlet Olive (red and white tipped); also known as French Breakfast. Of the turnip varieties there were Grey Round, Yellow Summer, Golden Yellow, White Summer, White Turnip, Scarlet Turnip, Early Scarlet, Early Deep Scarlet, and Early White. Messrs. J. Carter & Co. sent a collection of Peas preserved on the haulms, showing the respective heights, habits, and forms of the varieties. Messrs. J. Veitch & Sons, Chelsea, also contributed an extremely large collection of miscellaneous vegetables besides those named in the various sections referred to in these notes.

COMMITTEE MEETINGS.

The vegetable exhibits occupied so much space that little was left or required for fruit or flowers submitted to the Fruit and Floral Committees. The duties of the latter body were indeed very light and quickly performed, but there had not been a clear understanding that these Committees were expected to meet upon this occasion, consequently the attendance was small. The Fruit Committee was rather more busily occupied, Grapes and Melons being exhibited.

FRUIT COMMITTEE.—Present: H. J. Veitch, Esq., in the chair, and Messrs. A. J. Pearson, P. Crowley, W. Warren, J. Burnett, J. McIndoe, W. Denning, P. Barr, M. Dunn, G. W. Cummins, H. Balderson, J. Smith, W. Wildsmith, G. Wythes, J. Hudson, F. Q. Lane, J. Willard, J. Ross, and J. Wright.

The Thames Ditton Hero Melon was once more placed before the Committee by Mr. W. Palmer, who explained he had been compelled to grow the plants in a shady house with Cucumbers, and other fruits were cut from a cold frame. Those disadvantages may have prejudiced the quality, and the Committee were not able to recommend any special award. Mr. Miller, Roxley Lodge, Esher, sent a large ribbed Melon, which the Committee thought promising, and desired to see it again early in the season, when its flavour may be better developed. Mr. Waite, Glenhurst, Esher, sent two varieties of Melons—Glenhurst Perfection, not in condition, and desired to be sent again; Glenhurst Beauty, a peculiar flavoured Melon, was passed, but it is worth sending earlier in the season. A seedling Apple was sent by Mr. H. Stevens, Henley-on-Thames, and was passed. Mr. Edwards, Bickley, sent a collection of Apples, and was awarded a vote of thanks.

A basketful of Hutton Hall Sprouts, also growing plants, were placed on the table from Mr. J. McIndoe. This distinct vegetable originated in a plantation of Veitch's Exhibition Brussels Sprouts five years ago. It is really a Cabbage with side knobs. The Committee thought very highly of it, and desired to have it grown at Chiswick in accordance with the rule. We were subsequently informed that plants are now growing in the Gardens, and will be examined and the produce cooked in due time.

Messrs. Lane & Son, Berkhamstead, sent five Vines in pots, which were regarded as remarkable examples of good culture. They were trained round stakes, the bunches resting against wadding. We counted twenty on the Black Hamburg ripe and well coloured, some of them evidently nearly a pound each. A silver medal was unanimously recommended.

FLORAL COMMITTEE.—Present: W. Marshall, Esq., in the chair, and Messrs. Shirley Hibberd, R. Dean, R. B. Lowe, L. Castle, B. Wynne, G. Paul, J. Walker, E. Hill, and F. Moore. Messrs. H. Cannell & Sons, Swanley, exhibited a beautiful group of single and double Tuberous Begonias from seed sown in February, 1889, representing a large number of excellent varieties, rich and diversified in colours. The group was margined with Adiantums, and had a very pleasing appearance. Plants of Black Vesuvius Pelargoniums were also shown by Messrs. Cannell. The variety is distinguished by its dwarf compact habit, with extremely dark purplish tinted foliage and flower stems; the flowers are like the old Vesuvius, from which it is a sport. The Committee requested that it be tried at Chiswick. A silver medal was awarded for the group of Begonias. Several Pelargoniums raised by M. Lemoine, and tried in the Society's gardens at Chiswick, were submitted to the Committee, but all were passed. Mr. G. Stevens, St. John's Nursery, Putney, showed flowers of *Chrysanthemum Comte Horace de Choiseul*, a Japanese variety with

broad flat florets slightly drooping, white, yellowish centre. Flowers of Verbenas were also sent. Messrs. T. & J. Rogers, Fern Bank Nursery, Lodsworth, near Petworth, exhibited a plant of a seedling *Adiantum* like *A. macrophyllum*, but with the pinnules streaked with creamy white. The Committee asked to see it again. A plant of a hybrid *Cypripedium* much like *C. Lawrencianum* was also shown. Messrs. Veitch & Sons exhibited a box of *Rhododendron* flowers, including a dozen distinct varieties.

FIRST-CLASS CERTIFICATE.

Cyrtanthus sanguineus (J. Veitch & Sons).—An introduction from the Transvaal. The plant is about a foot high, with narrow leaves; the flowers rather bell-shaped, $3\frac{1}{2}$ inches in diameter, the acute perianth divisions somewhat recurved, the flowers borne singly on slender stems. This is a charming little plant, and was much admired.

AWARDS OF MERIT.

Tuberous Begonia Mrs. Moore (H. Cannell & Sons).—A fine single variety with large flowers, the petals broad, the colour a rich orange hue.

Tuberous Begonia Frank Beadle (H. Cannell & Sons).—A single variety, with well-formed flowers of a brilliant scarlet colour, of good substance.

Rhododendron Virgil (J. Veitch & Sons).—A bold variety, with a large truss of flowers of a soft yellow tint; the stamens red.

THE DINNER.

The Dinner, held at Cannon Street Hotel on Tuesday evening, was as successful a gathering as the Exhibition at Chiswick which it was intended to inaugurate, and when Mr. H. J. Veitch took the chair, shortly after 6 p.m., there were fully 150 horticulturists and their friends present. The Chairman was supported on his right by Mr. Henry Vilmorin of Paris, Dr. M. T. Masters, Mr. H. Pearson of Nottingham, Mr. G. Paul of Cheshunt, and Mr. Ker of Liverpool; on his left by Mr. P. Crowley of Croydon, the Rev. W. Wilks (Secretary), Mr. G. Deal, and Mr. J. Wills. At three of the side tables Mr. Shirley Hibberd, Mr. J. Wright, and Mr. A. Dean presided; and amongst others present were Messrs. J. Smith (Mentmore), W. Denning, B. Wynne, E. Molyneux, H. Cannell, J. Hudson, W. Bates, J. McIndoe, M. Dunn (Dalkeith), J. Wildsmith, J. Cheal, G. Bunyard, J. Walker (Whitton), W. Poupart, H. Herbst, G. W. Cummins, J. George, W. G. Head, G. Stevens, J. Kipling (Knebworth), J. Willard, H. Lister (Easton Lodge), G. Gordon, T. W. Sanders, and L. Castle.

After the usual loyal toasts had been proposed by the Chairman and duly honoured, the business commenced with the toast of "The Horticultural and Botanical Societies of the United Kingdom," proposed by Mr. Shirley Hibberd, who made some appropriate remarks respecting the example the Royal Horticultural Society ought to set the numerous provincial societies, and he thought in the past two years substantial progress had been made in the direction of elevating horticulture to a higher level. The toast was coupled with the name of the Rev. W. Wilks, who responded in his customary vigorous and pithy style, remarking that no one could be more pleased than he was to hear it said that the Royal Horticultural Society was making a satisfactory advance. Their desire was to extend its sphere of usefulness and render it serviceable to horticulturists, and through them to the public generally. Mr. M. Dunn also replied, stating that the Chiswick Exhibition was a good indication of the work the Society was capable of performing.

The Chairman next proposed "The Gardeners of the United Kingdom," and in doing so he commented upon the intelligence and ability characterising gardeners as a body, remarking that their remuneration was rarely proportionate to the knowledge required, and the results attained showed that much was done from a love of the occupation. He referred to the numerous difficulties gardeners have to contend with, the patience, perseverance, and foresight needed, and instanced amongst a gardener's trials the fact that reductions in the expenditure of large establishments usually commenced in the garden. But there is a bright side to the matter, for gardeners perform an important service to the community, doing much to elevate taste and improve moral feeling throughout the country. Referring to allotment gardening, he pointed out that much may be done in this direction in coming years, and gardeners might do much to instruct those engaging in this work. Mr. J. McIndoe and Mr. E. Molyneux replied, the latter giving an instance of what can be effected in cottage garden and allotment societies from his own experience in the Bishops Waltham district.

In proposing "The Visitors," the Chairman mentioned Mr. Henry Vilmorin as one of the best representatives they could have of the Continental seed trade, and complimented him upon the systematic arrangement and admirable management distinguishing their great business in Paris. M. Vilmorin responded in excellent English, stating that he had for many years been familiar with British horticulture and gardeners, and he came over on this occasion with great expectations respecting the Vegetable Conference, and had not been disappointed. It was the most comprehensive display of the kind he had seen, and the Society had good reason to be satisfied with the result of their efforts.

"The Horticultural Trade" was next proposed by Mr. G. Deal, Mr. N. Sherwood replying; and it was followed by "The Committee of the Vegetable Conference," proposed by Dr. M. T. Masters; and Mr. A. Dean in reply said that his *confrères* and himself had endeavoured to make the vegetable gathering a success, and he stated that they owed much to their Chairman and Mr. Shirley Hibberd, Mr. J. Wright and Mr. Wythes also having rendered good service in the work of preparation.

"The Health of the Chairman," proposed by Mr. Shirley Hibberd, was received with acclamation, rendering, as the proposer justly observed, any eulogy on his part quite unnecessary.

Mr. Veitch expressed his gratitude for the manner in which his name had been received, and mentioned that they must not omit to thank Mr. A. Barron for his good services in the matter. He knew that nothing could add to his credit, but the fact should be recorded. The thanks of the meeting were also due to Mr. Wills for the handsome Palms, and to Mr. H. Cannell for the Tuberous Begonia flowers employed in the decoration of the room and tables.

An excellent programme of songs and music was arranged by Miss Mary Belval, and carried out by herself, assisted by Miss Harriett Boutall, Mr. Wilford T. Price, and Mr. John Bartlett, and at a comparatively early hour in the evening the visitors separated well satisfied with a most enjoyable gathering.

FRUIT FORCING.

VINES.—Midseason Houses.—Vines from which the Grapes have been cleared should now be divested of their laterals down to the principal buds, that are to be retained for next year's fruiting, doing so, however, without injury to the old leaves, as upon their preservation depends the maturation of the buds, which should be plump and well ripened. A free circulation of air is necessary, and in the case of young Vines, or where there is the least doubt about the thorough maturity of the wood, fire heat will be necessary. When the laterals have been removed clear the old mulching off the borders, and give a top-dressing of turfy loam, with about a sixth of manure and a sprinkling of bone meal. If the roots have not penetrated the mulching remove the soil down to them and supply fresh compost, but not covering them deeply; 2 or 3 inches depth is quite sufficient. In the case of inside borders afford a moderate watering, and allow those outside to have the benefit of October rains, but instead of adding manure to the loam mulch the surface with 3 or 4 inches of fresh horse droppings, covering with dry litter or bracken by the end of October or early November. In the case of borders only partly made a breadth of 2 feet may be added to the front, choosing a dry day for the operation, mulching with horse droppings, and cover as before advised.

Late Muscats.—If not thoroughly ripe continue rather sharp firing in the daytime with a free circulation of air, and enough at night to prevent the deposition of moisture on the berries. Continue this until the Grapes are finished, when a gradual reduction of temperature must take place, about 50° at night being necessary for Muscats after they are matured. Moisture must be kept down by a buoyant atmosphere, a pent up air with a sudden increase of temperature from sun being sure to induce moisture to condense on the berries, which will cause spot, and then the Grapes will speedily decay. The inside border should be covered with clean dry straw or matting to prevent moisture rising.

Late Grapes.—Make sure that the berries are well finished quite up to the shank before ceasing the needful aid from fire heat. Alicante and Lady Downe's invariably finish better than Mrs. Pince, which, though the best flavoured of the late or thick-skinned varieties, is somewhat difficult to treat satisfactorily, the berries not finishing well up to the shank. Well grown it has the full flavour of Black Muscat. Gros Guillaume and Gros Colman require more time, as also do the white varieties, Syrian, Trebbiano, and Calabrian Raisin. Indeed all thick-skinned Grapes require a long time to mature after being apparently ripe, consequently a temperature of 55° should be assured, with a rise of 5° to 10° by day, and a circulation of air until the foliage is giving indications of falling, when a temperature of 50° will be sufficient. The inside border must not be allowed to become too dry. If necessary water in the early part of a fine day, and cover with a dry mulch as a safeguard against damp, and a repetition of the watering. Outside borders will be quite damp enough, and should be covered with lights preferably, or some other means employed to throw off heavy rains.

Late Hamburgs.—These colour and finish when it is hopeless to do anything more with the thick-skinned varieties. They should have a temperature of 60° to 65° at night, and 70° to 75° in the daytime, with a circulation of air constantly, not allowing the borders to become dry, but giving a good watering if they are only partially advanced in ripening, and mulch with rather short dry material. Only restrict the laterals to prevent overcrowding, but after the Grapes are finished avoid further extension, yet not reducing the foliage much, as this assists Hamburgs to keep their colour.

Houses of Ripe Grapes.—Hamburgs and all thin-skinned varieties of Grapes require frequent examination for the removal of decayed berries. Damp being their greatest enemy it should be prevented as much as possible by fire heat in the daytime, accompanied by free ventilation, allowing the house to cool before night.

Young Vines.—Vines planted this spring or in early summer will

need every encouragement in keeping the foliage clean and healthy, also keep the laterals away from the principal leaves in order that they have free exposure to light and air, especially those at the base of the canes, so that the buds to which the Vines are to be pruned may be thoroughly matured, and the wood well ripened. In order to insure the ripening of the wood maintain a genial warmth by day, and throw the house open at night.

FIGS.—Early Forced Trees in Pots.—Examine the roots, and as it is not advisable to increase the pot room, remove a few inches of soil from the base, cutting back the roots, and supply fresh fibrous loam, adding about a tenth of old mortar rubbish and a sprinkling of crushed bones, providing good drainage. Remove the loose surface soil and apply the above compost, adding a fourth of well decomposed manure. Afford a good watering, place the trees where they can have plenty of air with shelter from heavy rains and frost.

Planted out Trees.—Keep the trees dry at the roots, but avoid extremes, and a drier condition of the atmosphere will tend to promote the perfecting of the growth. As soon as the latest trees are cleared of their crops keep them down at the roots and the house well ventilated in favourable weather. Any root-pruning or partial lifting should be done when the leaves show indications of falling.

THE FLOWER GARDEN.

Dahlias.—Already we have had a rather severe frost, and in cold low-lying localities many of the Dahlia leaves have been blackened. Last year all were completely spoiled during the first week in October, and it is wise therefore to be prepared for eventualities. All the plants should be examined, those raised from seed being especially taken note of, any not worth keeping being duly singled out and marked. Those with names should be re-labelled if need be, and in any case the height of each variety ought to be marked on the label or entered in a book. It will be useless to attempt re-labelling after a severe frost has crippled the plants, and unless, therefore, it is done at once much confusion may be the result next spring. After the foliage and flowers have been blackened by frosts the plants should be cut down to within 8 inches of the tuberous roots, and be then lifted without damaging the latter. Store them stalk downwards in a dry open shed for a few days, or till they are thoroughly dried, after which they should be packed closely together on the floor or on a bench in a dry cool room or shed, covering all but the upper portion of the stems with fine dry soil. In very cool sheds it may be further necessary to cover with mats, sacking, or old carpets in severe weather, but, as a rule, no further trouble need be taken with them.

Tuberous Begonias.—Much that has been advised concerning Dahlias also applies to these. They can be potted up fairly well from the open ground, and will flower for a few weeks longer in a cool house or conservatory. Those left to face the weather ought not to be disturbed till the tops are injured or cut down by frosts, when the tubers should be lifted, a small quantity of soil being left on them, and after they are slightly dried all ought to be packed closely together in boxes of moderately dry soil. They can be kept in any cool place, taking care to protect them from severe frosts and drip. Seedlings still in the seed pan or the boxes in which they were pricked out are best left undisturbed, being kept cool and dry. They will be very serviceable next season.

Zonal Pelargoniums.—These will withstand a moderately severe frost, but the choicer varieties, or any of which an insufficiency of cuttings have been taken, ought to be lifted before the points have been blackened by frost, or otherwise they will keep badly. All that are to be kept ought to be carefully forked out of the ground as soon as the state of the weather or the appearance of the beds warrants those in charge to break them up. It is useless to attempt preserving soil with the roots, but as few of the latter should be damaged as possible. First pinch off all the old or fully grown leaves, preserving the smallest at the points of the shoots only; each plant may then be placed singly into as small pots as the roots can be crowded, or better still, from five to seven may be packed into 5-inch or rather larger sizes. In any case moderately moist soil should be used, and this must be well rammed about the roots. They will be more certain to recover somewhat and form a few roots if all are placed in gentle heat for about a month, sufficient water only being given to prevent shrivelling. During the winter they ought to be kept in a comparatively cool dry house, only enough water being given to just keep them alive. If they cannot be given the benefit of a little heat when first potted they must be placed in a cool dry house or pit and kept dry at the roots. Large quantities of Pelargoniums are frequently wintered in coach houses, spare bedrooms, and other fairly warm dry positions where only a moderate amount of light reaches the plants. In all such cases it is of the greatest importance that all the old leaves be picked off at potting time, and that the plants be kept quite dry at the roots. They must be kept in a dormant state. It is not yet too late to put in strong firm cuttings, but these must be placed under glass, preferably on shelves, at once, and not watered for about a week.

Various.—Carpet beds may be preserved in an attractive state for several weeks longer if protected with blinds or mats every cold night. Any choice "dot" plants there may be used in these or sub-tropical beds, and which are plunged in pots, can be taken under cover of a house every night, or whenever there are signs of a frost, and returned in the morning. It is also advisable to ward off cold rains as much as possible. If stock plants of Coleus, Iresine, and Alternanthera are needed these must be potted before being badly crippled by frost. Not much of

the soil should be preserved with the roots, as this is usually too close and heavy for plants in pots, and sours quickly. Avoid overpotting, and place the plants in gentle heat at once. Heliotropes, Ageratums, and Petunias as a rule cannot be well potted, but some, if cut rather hard back, will survive. Fuchsias ought not to be lifted and stored in pots or boxes until after the principal portion of the leaves have fallen. Marguerites can be readily potted, and will flower in a conservatory or greenhouse for some time longer. Strong autumn-struck plants are the best for window boxes and vases, or for an early display in any position. *Salvia patens* having tuberous roots may be treated exactly the same as Dahlias, or if not numerous the roots may be stored thickly in boxes of fine soil. Abutilons are readily potted, and the majority, whether flowering varieties or grown for their fine foliage only, will help to brighten a conservatory. Asters are in many instances past their best, but any not so forward may be potted, and will be found very serviceable. As a rule Dahlias do not move well out of the open ground, but occasionally plants carefully lifted and potted pay well for the trouble. Succulents, notably the choicer *Echeverias*, *Pachyphytums*, and *Sempervivums* must not be left in the open till a severe frost cripples them, or otherwise they will keep badly through the winter. The middle of October is, as a rule, quite early enough to put in cuttings of *Violas* and shrubby *Calceolarias*. They will be firmer by that time, and the less growth they make before midwinter the more serviceable they are subsequently.

PLANT HOUSES.

Housing Plants.—Tender plants are not safe outside after the close of this month without some protection. It is important that all available structures be thoroughly washed and cleaned before the plants are arranged in them. All needing stove or an intermediate temperature should first be provided for. The pits and frames they have occupied can be devoted to the protection of plants that have been grown outside. All plants that need cleaning should be attended to before they are arranged in their winter quarters. In the neighbourhood of towns it is not only necessary to wash the glass inside, but it must be done outside as well. The latter can be left, however, until all plants are safely housed, and during showery weather outside washing does not take up much time.

Shading.—Discontinue all shading, take the blinds off, and thoroughly dry them before they are stored away for the winter. If placed away damp they will be useless when they are required next spring. Where thicker blinds are used during the winter on stoves and other warm houses place them on at the same time as the summer blinds are removed. Covering the roof of warm houses during cold severe weather should be more generally practised. It prevents the overheating of the pipes, which is of the utmost value for the well-being of the plants, and the saving in fuel will soon more than cover the first outlay for blinds.

Callas.—Lose no time in lifting those planted out, as although they will bear a few degrees of frost it checks them. Carefully shake the soil from the roots, and place plants into convenient sized pots in a compost of good loam and one-third of decayed manure. One large crock, even in 10-inch pots, is ample drainage for them. Pot firmly, soak the soil with water at once after potting, and syringe two or three times daily until root activity has commenced. The plants may be stood outside for ten days or a fortnight before they are housed, but where they can be covered with a piece of tiffany. Lift also *Salvias*, *Eupatoriums*, *Bouvardias*, and other plants of a like nature. These should be placed in cold frames, and shaded for a time from the sun.

Solanums.—Where these have been plunged outside in pots, and have rooted out at the base and over the rim, no harm will be done by cutting them off. If stood afterwards in a dry place the foliage is liable to turn yellow. Place them in a frame for a fortnight, and keep the soil moist at their roots, and syringe freely. This is all that is needed to keep the foliage fresh and healthy.

Hydrangeas.—If cuttings have been rooted and stood in a sunny position outside it is necessary to look over the plants before they are checked or injured by frost. Those with plump flower buds can be left outside until frost sends them to rest, but those in a backward state may be placed in a sunny position under glass on a shelf, and it is surprising how quickly the buds will plump up. Plants subject to this treatment are not, as a rule, good for early forcing, but will prove all that will be required for successional purposes.

Chrysanthemums.—All plants required for flowering during November should be placed under glass. The early frosts of last year, and the slight warning we have already received this year, warrants the advice that they should be placed under glass as quickly as possible. Those required for late flowering should be so arranged that slight protection can be given when necessary. Bushes for decoration are being arranged three rows together. Long canes are placed into the ground on each side, and tied together in the centre. An upright stake is placed in the centre, to which these are secured. A few lengths of tar twine run along each side completes the arrangement as far as the framework is concerned. Long strips of tiffany are then secured at the top and rolled up and tied against each other. With this or any similar provision large quantities can have the covering drawn over them in a very short time, the tiffany only needs securing to the stakes at the base. Where practicable the pots should be plunged, which prevents the plants being rolled about by rough winds. When these plants are first housed discontinue feeding for a few days, and give abundance of air. Syringe liberally two or three times during bright days. Syringe lightly just before dark.

Carnations.—Tree varieties should be housed at once, and if aphides

exist upon their shoots fumigate them slightly with tobacco. Arrange them in a light airy position on a moisture-holding base. Water the plants carefully, but do not allow the soil to approach dryness.

Azaleas, Heaths, and Epacris.—Place these in their winter quarters, as heavy rains will soon prove injurious to them. Arrange them on a base covered with gravel or ashes. The flowers of Heaths and Epacris failing to come forward is frequently due to placing the plants on dry stages, and maintaining about them a dry atmosphere. Where plants have to be placed on dry stages the pots and stages should be frequently syringed. On all fine days the plants will be benefited by being syringed lightly twice daily.

THE BEE-KEEPER

THE HEATHER SEASON IN HALLAMSHIRE.

THE past contributions of "A Lanarkshire Bee-keeper" have been very interesting, and as the Heather here behaves very differently from that in his locality, a few notes on the subject may be acceptable.

He speaks of bees filling supers from Heather in July, and swarming when working on the Heather. Here the Heather yielded no honey before August 10th, which was earlier by five days than the average, this being the earliest date I have ever known. How is it that the Heather in Scotland yields honey so much sooner than here? Perhaps the reason is they get more sunshine in the north, which helps it forward. It is a fact not always remembered, that the sun shines longer in summer the further north we go, and this may account for the wonderful Scotch Heather harvests.

I have never seen or heard of bees swarming while the Heather is in bloom here, no matter how strong they might be, and I often have them supersede their queens whilst it yields honey; in fact, I have had far too many queens superseded this year.

This year has not been good, the best days being August 30th and September 10th; from the 14th to the 28th, when the Heather was at its best, the weather prevented their procuring anything, but it has yielded longer than usual this year, and most stocks will yield twenty 1-lb. glass sections sealed over, with 30 to 40 lbs. in the combs below. I feel quite disappointed, as I never saw the Heather look so well before, and the only consolation is we had none last year.

Our friend speaks of one stock collecting 30 lbs. in one day, and as I understand him to say that he weighed the hive in the evening I think a large deduction should be made to obtain the equivalent in ripe honey—that is, assuming his Heather honey is anything like ours. When first gathered it is as thin as water, and is scarcely sweet. The bees evaporate it down, which, with the honey used as fuel, will at least reduce the weight to one-fifth. In 1887 I had one stock of hybrid Syrians increased 70 lbs. in weight, all sealed honey, which was gathered in seven days, but I never saw Heather honey so thick when first gathered as it was that year.

I do not question or doubt the possibility of bees collecting 30 lbs., or even 100 lbs., of crude Heather nectar in one day; but I am rather sceptical that they can possibly ripen 30 lbs. per day. This brings me to an idea I have been thinking of to help them—viz., all who have had any experience with Heather honey know that it cannot be extracted when ripe, though when fresh it is extracted most readily. Even on the third day, in fact, every bit of Heather honey can be extracted if the combs are run through the extractor once in three days. I have been thinking that if the super combs were extracted every alternate day the watery part could be separated by centrifugal force, like cream is separated. This water would contain a large portion of the bitter flavouring,

and could be extracted and added to the honey or not. I do not think it could be made to pay on a small scale, but as there is no limit to the number of stocks we can locate on the Heather, a "separator" and horse to work it would pay well with 100 stocks; then the bees could be kept at work collecting, and the market supplied with bottled Heather honey without having to destroy the combs.

The Punie bees pure have outstripped all others again, but I am disappointed with Punics crossed. One lot, Carniolian queen mated to Punie drone, has, however, done remarkably well, but all mis-mated Punie queens have done badly.

With regard to glass sections I think I cannot do better than relate an unpleasant circumstance that happened on September 7th, just to show what these will stand in the way of rough handling, as grave doubts have been expressed about it being possible to safely send them a journey, though I demonstrated that they could travel for months through the post.

A well known member of the Sheffield County Council and myself were up at the moors in a dog cart. I placed four filled glass sections in a green gin box, which I use for makeshift hives, and filled the box with sealed ordinary combs in frames, and placed the box in the trap behind. All went well till we were nearly home, when turning a corner in the dark at full trot we ran into a heap of stones, and over we went, horse, trap, and everything. The box with the honey was thrown into the road as well as ourselves; and while I was helping to extricate the horse some of the crowd began to examine the honey. However, when I could leave the horse I found three of the sections quite sound, except some slight scratches made by the crowd; the fourth had a top and one side torn off, otherwise it was sound, this I also think was done by the crowd. The combs in the frames were all broken out. The sections were the least injured of any. So that if they will stand being thrown out of a trap into the middle of a hard road, without being packed in any way, I think they will stand any risk they may be subjected to in the ordinary way.—A HALLAMSHIRE BEE KEEPER.

TRADE CATALOGUES RECEIVED.

Bruant, Poitiers, Vienne, France.—*Catalogue of Plants.*
H. Bennett, Shepperton.—*List of New Pedigree Seedling Roses.*
Dicksons, Chester.—*Select Roses.*
J. Walters, Exeter.—*Catalogue of Roses.*
T. Warner, Leicester.—*Select Fruit Trees.*
Dicksons & Co., 1, Waterloo Place, Edinburgh.—*List of Select Roses.*
W. Crossley, 13, Vicar Lane, Leeds.—*Catalogue of Roses, Bulbs, &c.*

* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Covering Bulbs (G. W.).—Coarse sand will answer, but we prefer cocoa-nut fibre refuse to any other material; it is cheap, and useful

for many purposes in gardens. Great pressure compels us to defer our reply on the other points in your letter till a future issue.

Drawing (A. D.).—Probably if you write Messrs. Cassell & Co., Ludgate Hill, London, they may be able to send you a list containing what you require. The subject is treated in their "Popular Educator," and possibly they may have a treatise on the subject. A good local schoolmaster would show you how to draw a plan to scale.

Offsets on Crinum (M. D.).—Under the circumstances we should not attempt to separate the offsets from the plant, but wait until the next resting period, and this will depend on the temperature in which the plant is kept and the treatment accorded. Their removal during active growth might injure the plant materially.

Caterpillar (W. H.).—The specimen sent is a nearly full-grown caterpillar of the Elephant Hawk Moth (*Chærocampa Elpenor*), so called from its mode of extending the head while feeding. It usually feeds upon some of the species of Epilobium or Willow Herbs, but sometimes occurs upon the Vine in houses or out of doors, eating only the leaves, and in numbers too small to be injurious.

Ashes from Vegetable Refuse (A. D.).—You are wise in not allowing the chaff that is mixed with the stems and seed of Charlock to be mixed with manure for the land. Reduce the whole, with all the vegetable refuse you can collect, to ashes, and the residue will be valuable for the garden. It will be good for all kinds of fruit trees, also for sowing in the drills for various kinds of seeds and Potatoes.

Bunches of Flowers (M. C.).—The number of flowers sold in bunches varies considerably according to the season. An article in our issue of September 25th states that 120 spikes of Lavender are usually sold in bunches; more if the spikes are small. Single Dahlia bunches usually contain twelve good flowers, but often more. Cannot you consult a florist in the town in which you reside? There is no work on the subject.

Insects on Strawberries (W. R.).—The extremely small portions of leaves sent, and these resting in the post over Sunday, were completely shrivelled, and what insects may have been on them have shrivelled to the vanishing point. It is not improbable the plants have been attacked with red spider and mildew, and the lower temperature with frost imminent or actual will check the increase of both. If the plants are old they may be exhausted and peculiarly liable to attack by those enemies. If young the soil may be deficient in the requisite matter for supporting healthy growth. If you wish for further information, and will state the varieties and age of the plants with the nature of the soil, we shall be glad if we can give you further advice.

Wood-boring Caterpillar (J. L.).—This is a caterpillar of the wood leopard moth (*Zeuzera Aeseuli*) which does every year a considerable amount of injury to a variety of trees. Amongst the fruit trees it seems to infest the Pear most frequently, but also attacks the Apple, Plum, and Walnut, probably remaining in the larval state the greater part of two years. Sometimes as many as fifteen or twenty caterpillars have been discovered in a small Ash, a tree particularly visited by the moth, which lays about 300 eggs. It is recommended to force up the holes, whenever these are seen, a flexible wire, by which the caterpillar within may be often killed, and it is also a good plan to throw up the holes, by means of a syringe, some insect-killing liquid, such as a compound of tobacco and softsoap, suitably diluted. This species would, no doubt, be much more abundant were not the moth eagerly eaten by birds.

Mealy Bug on Vines (J. C., Somerset).—Your Vines are infested with this offensive pest, and it is difficult to eradicate from a greenhouse which always, we presume, contains plants. Fumigation is of no use, and a thorough cleansing of the house, plants, and Vines is imperative. When the leaves turn yellow take them off and burn them, not letting any of them fall among the plants or to the ground. In that way you may clear out thousands. The cleansing cannot be thoroughly done till the Vines are pruned. The insects lurk, not only in the bark, but in bits of matting attached to the Vines, in woodwork, especially on the under sides of shelves, in dry soil in pots and borders, and in all sorts of what you may consider the most unlikely places. The Grapes you send are unfit for table. You have a difficult task before you in extirpating the pest. Some of the leaves you send are scorched, and the appearance of those that are not suggests that the house has not been ventilated in the best manner. In all probability also the roots need more support than they obtain for the proper sustenance of the Vines.

Roses for Buttonholes (S. T.).—Tea Roses are among the most suitable for this purpose, and there are a few gardens where the soil is good and the atmosphere pure in which they, with a little protection, may not be grown. Free and good are Niphetos, Madame Falcot, Homère, Madame Van Houtte, Madame Lambard, Safrano, Perle des Jardins, Comtesse Riza du Pare, Madame Jules Margottin, and Souvenir de Paul Neyron. The old crimson China Rose and Cramoie Superieure are good for your purpose, as also are the Noisettes Triomphe de Rennes and Aimée Vibert, with Baronne de Maynard, Boule de Neige, and Louise Darzens. Moss Roses are indispensable—the common, crested Moss de Meaux and Little Gem (W. Paul), the latter being very charming. Among the most free and suitable of the Hybrid Perpetuals are Jules Margottin, Général Jacqueminot, and La France. We have probably named sufficient for your purpose. The advisability of digging-up and

planting your established Roses deeper depends on the depth at which they are planted now. If they grow and flower freely we should let them alone; if not, you might try the plan you suggest, but on this point we cannot advise, since you have not stated the length of the stocks.

Leather Parings (O. R.).—They are very good for furnishing nitrogen to plants, but nothing more. Of this nitrogen clean samples contain as much as does nitrate of soda; but it does not follow that they are therefore of equal value, as in the one the nitrogen is at once available but in the other it is not. Still, good samples are worth £2 or £3 per ton to manufacturers of manure, and if you could find a market for them the money they might fetch would be better spent by you in the purchase either of manufactured or ordinary dung, for by themselves they are not true manure. But if a tenth were added to ordinary manure, and overheating provided against by keeping the heap fairly moist, the value of the manure would be doubled. Allowing them to heat by themselves is almost certain to cause loss of nitrogen, as the sense of smelling would inform anyone; but in the bulky manure the ammonia would be absorbed and preserved. The fact that the farmers in your district will not have the material you mention for the carrying only proves the necessity there is for farmers becoming acquainted with agricultural chemistry. We could name a district where they will not look at sewage, but cheerfully pay for and convey long distances broken bottles, earthenware, tin cans, cinders, and a little town's dust! Tanned refuse, such as bark, is of little use except for mixing with heavy soil to render it lighter. The process of tanning adds no manurial value to anything. Fine leather shavings unmixed with other matter are used for fruit trees in the London market gardens, also for Filberts and Hops.

Dr. Hogg Grape (Cambrian).—We cannot account for your failure with this Grape, for it is a good grower and bearer, and usually sets freely; but if you expect large berries, like Muscat of Alexandria, you are bound to be disappointed. It belongs to the Frontignan class. The following is Mr. Barron's description and estimate of merit as they appear in "Vines and Vine Culture":—"Growth free and vigorous, producing firm, moderate-sized wood, which always ripen well; very fruitful. Leaves medium sized. Bunches long, measuring from 12 inches to 18 inches, and tapering to rather a narrow point; shoulders long and rather loose, drooping, always well set. Berries medium sized, round, on strong stalks. Skin membranous, very clear, almost transparent, and, when quite ripe, assuming an amber tint. Flesh firm, very sweet, and with a rich Muscat or Frontignan flavour. This is a seedling raised by the late Mr. Pearson of Chilwell, about 1869, from Duchess of Buccleuch, and was exhibited before the Fruit Committee in 1871, and awarded a first-class certificate. It is now very general in cultivation, taking the place of Chasselas Musqué. Succeeds well in an ordinary vinery, but requires a little more heat than the Black Hamburgh to ripen thoroughly. It is, however, one of the hardiest of its class." If your Vine is healthy you may inarch a Foster's Seedling on it as you propose, if you prefer this variety, which is a good grower and free bearer. The other you mention is not nearly so certain to succeed with you as is Dr. Hogg.

Orange Trees Unhealthy (R. O.).—An application of lime water would not have the good effect you anticipate. Defective root-action is the chief cause of the unsatisfactory condition of the trees, and undoubtedly it would be better if you could prevent the temperature of the house falling so low in the winter. You can do little to them now, but may improve them in the spring, and in the meantime avoid over-watering. As soon as signs of fresh growth are apparent we should dig out the soil from the tubs quite to the bottom, and remove it as near to the stems as possible without materially disturbing, or at least not injuring, the roots. We have seen much more than half the soil thus removed, and by adding fresh, such as turfy loam and a liberal admixture of crushed charcoal, bones and wood ashes, the roots being carefully placed in this, and the whole made as firm as the soil not removed, water being judiciously applied, and old trees were made young again. It does not at all follow if the roots are few and the tubs large that they should be filled at once with soil; but the soil may be supported with a wall of turves several inches from the sides of the tubs, precisely on the principle of making a Vine border in sections. By adopting this plan and keeping the plants as warm as possible in the spring, syringing freely in fine weather, and keeping the foliage scrupulously clean, the trees will improve. The surface soil immediately round the stem should also be removed, and all dead and dying branches cut out; indeed, as soon as roots take possession of the fresh soil rather close pruning would result in stronger and healthier growths.

Scabbed and Cracked Pears (J. R. G.).—There may be more than one cause of cracking in Pears, but your examples are in bad plight—indeed one of the worst cases we have seen. It is the work of a fungus called *Cladosporium dentriticum*, *Walls*, which grows on the young twigs and leaves, also on parts of the flower, preventing some of the fruit setting, and those that do set are injured and crippled in growth, and are mostly of little value, through the cracking of the skin of the fruit as it ripens. The fungus gives rise to black spots on the leaves a quarter to half an inch wide. On the fruit it occasions similar spots, irregularly rounded, forming a depressed black spot. The mycelium of the fungus does not penetrate far into the fruit, but remains almost wholly in the cells of the epidermis. The spots not unfrequently run together, covering a large portion of the surface of the fruit. There is no known remedy; attention, therefore, must be directed to prevention,

and we know of nothing so effectual as lifting and replanting the trees in good fresh loam—the top spit of a pasture. Certain varieties are peculiarly liable to injury by the fungus, and it usually attacks those for which the climate is unfavourable, as the sorts produce worthless fruit on pyramid, espalier, and other form of trees in the open, while against walls with south or west aspects trees produce clean and fine fruit. Diseased trees and all fruits that assume the diseased condition should be destroyed. Selection should be made of varieties that succeed in the locality. Those that are known to be peculiarly liable to injury from the fungus should not be planted, so as to prevent, as far as practicable, liability to infection.

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (*C. J. N., Loughgall*).—1, Golden Reinette; 2, None-such; 3, Scarlet Pearmain; 4, Blenheim Pippin; 5, Lewis' Incomparable. (*E. J.*).—1, Beurré Clairgeau; 2, Vicar of Winkfield; 3, Pit-maston Duchess. (*A. D.*).—The Apple appears to be Cox's Pomona. (*H. W.*).—2, London Pippin. 3, Perhaps a small Russian Transparent. 4, Dumelow's Seedling. 5, Ribston Pippin. 6, Scarlet Nonpareil. The plant is *Hieracium aurantiacum*.

COVENT GARDEN MARKET.—SEPTEMBER 25TH.

LANDLORDS' FARMING.

SOUND policy is it always to encourage tenants to drain land by the landlord supplying the pipes, upon condition that the tenant makes the drains subject to the approval and inspection of the agent. Had this been done more generally the landlords' burden now would be much lighter than it is, for the only thing to do with a neglected farm falling in hand is to bring it into sound condition as soon as possible, and drainage forms the basis of all such improvement. It is not to be set aside indefinitely, but is of such primary importance that it must have due attention before any manure is used. To apply manure to wet land is mere waste, the inert soil derives no real benefit from it, and disappointment follows the sowing of any crop. Singular indeed is the ignorance which still prevails among farmers about the effect of and necessity of drainage. During the recent harvest a tenant farmer was loud in his complaints about a small crop of Wheat on heavily manured land which he had folded twice and then manured. He is a sharp shrewd man of business, and we doubt not that our explanation of the want of drainage being the cause of the failure, and why it was so, will be turned to practical account. But is it not remarkable that a man born and bred to farming should arrive at middle age and yet remain ignorant of a matter of such vital importance? He at first said that he did not think the land was wet, but we were bound to show that the failure was a simple case of cause and effect; that without a free passage of water through and from the land there could be no circulation of air in it, no absorption of fertilising gases by it, no kindly root-action in it, so that anything like robust growth and full crops were impossible. If only farmers could grasp the full significance of all this and would test the condition of the soil which they essay to cultivate, and not trust so much to the imagination, it would be greatly to their advantage.

In land drainage no rule can be laid down, the nature of the soil and subsoil being the only safe guide. The drains may have to be any distance apart, from 15 to 30 feet, and any depth from 20 to 40 inches, or even more. It is true that capillary attraction is active in clay, but it is only in exceptional cases that very deep drains are necessary in clay. We may mention once more that deep drainage is intended to keep the water table so low—so far from the surface—as to prevent the excessive rising of moisture from it by attraction, and so check that excessive evaporation which tends to lower the temperature of the surface so seriously as to prove hurtful to vegetation. Our especial object in calling attention to drainage here is to induce caution in the autumn cultivation of farms falling in hand now. The aim is naturally to sow a certain proportion with winter corn, but if the drainage is deficient far better will it be to refrain, and rather to do what is possible in clearing the land now, to ridge it up roughly for winter, to drain as much as possible during winter, and then to sow spring corn with a full dressing of pure home mixed chemical manure next March. Pray do not listen, or rather pay no heed, to prejudicial remarks against the use of such manure. The land is practically exhausted of fertility; the only sure way to impart sufficient fertility to it so as to insure full crops next season is to use full dressings of carefully mixed mineral and nitrogenous manures when the corn is sown. Care must of course be taken to obtain the manure from a reliable source and to avoid all risk of adulteration. Do what you can later on by sheep folding and with farmyard manure, but pray rise to the emergency and let nothing prevent the use of chemical manures, for the first season at any rate. It is precisely because we have so used them that we have been so successful in our treatment of exhausted land. No doubt there is

a certain risk of waste in using such manures upon land newly in hand, but that cannot be avoided; the object is to store it with plant food, and provided each element of fertility is there we do not mind a little in excess. We want a crop, and it must be a full one, and then it will cover expenditure and afford some profit.

Every outgoing tenant farms for a valuation, and therefore he usually has a certain proportion in fallow. If this is a bare fallow and the drainage is sound it is immediately available for Wheat sowing, with a half dressing of chemical manure well harrowed-in before the drill, or better still, if an Excelsior drill is available, drill the manure with the corn. We have every reason to recommend this plan, for the manure is dissolved and taken up by the soil immediately about the seed; the seedlings thus have a full supply of food from the outset, the growth is proportionately robust, and the supplementary spring dressing is far more effective than it ever can be when the seedlings have been in a state of semi-starvation during winter, and a crop that is robust from the beginning comes to maturity much sooner than that which is weakened by poverty of soil.

(To be continued.)

WORK ON THE HOME FARM.

Most pleasant has been the sight of couch fires, muck carts, ploughs, broadshares, cultivators, and harrows all in full activity upon the clay soil of late. Now, if ever, good management tells, and we have not to look far for evidence of it. Take for example a recent visit to two of our farms. At the first we found every corn stack had been thatched, as it was built by that handy man who is so indispensable on every large farm. Stubble clearing was being done, and so too was the carting of manure. The second growth of Clover had been folded by the ewes, and the layer was being ploughed in for Wheat. Part of one large field had of necessity been a bare fallow, the other part had been under Peas, and the whole was being got ready for Wheat. To the bailiff's inquiry if the fallow should be again ploughed with the Wheat land, our answer was, "No, the fallow is clean, time is precious, and besides, you will have the opportunity of trying the merits of stale and fresh furrows, about which there is much diversity of opinion." At the other farm we found several corn stacks still unthatched, carting not begun, no stubbles cleared, and work generally in arrears; yet the bailiff is, in his way, a good man, perfectly honest and trustworthy, but sadly deficient in capacity to organise labour and turn it to best account.

We had much difficulty in getting land ready for winter Beans last autumn. This time we are able to sow in September, before the Wheat sowing. Of the two spring Beans have proved altogether the best crop this year. They were the last crop out on the land, but they are now safely in stack in capital condition. Never did we see finer crops of green Maize. Some of the plants are 10 and 11 feet in height, and the bulk per acre must be far above the average. Rich soil and a hot showery summer ensure a full crop of this valuable forage plant. All live stock eat it greedily, and nothing can be better for cows where the milk is sold. For home-farm dairy cows it has to be used with some caution, as it is apt to impart an unpleasant flavour to the butter. We are glad to find our old favourite the Kerry cow is at length making its way to the front rank of dairy cows. We have long regarded it as no mean rival to the Jerseys, for we have found it yield very rich milk abundantly, and it has the additional merit of being hardy, easily fattened, and fed at a comparatively low cost compared with that of most other cows.

REMARKS.

15th.—Fine morning, but not sunny; fine day and night.
16th.—Fair morning early; dark at 11.30 A.M.; generally dull and overcast, and chilly dull evening.
17th.—Fair bright day and night, but chilly.
18th.—Fine bright morning; cold day, with occasional sun: fine night.
19th.—Dull and overcast generally; cold and rain from 2 P.M. to 7.15 P.M.
20th.—Fine breezy morning, with occasional sun and rain and hail at 3.15 P.M., and then fine with some sun.
21st.—Fair morning, with occasional gleams of sun, sharp rain in the afternoon, and dull damp evening.
The week has been generally cold with rain. The temperature about 13° below that of the preceding week, and 4° below the average.—G. J. SYMONS.

NOTES ON SOILS.

WE are told by vegetable physiologists that primitive soils or pure earths are of no other use or benefit to plants than merely affording them a medium by which they fix themselves in the most favourable position with regard to their future growth. Luckily the horticulturist has little to do with pure earth, it is only when soil is more or less charged with organic matter that it is in any way fit for his purpose, and in proportion to the presence or absence of this matter is the value of the soil to be estimated, superabundance or deficiency to be corrected. Various are the operations for improving soils independent of manures; and it is a more serious consideration to the gardener than to the farmer. For instance vegetables grown in the fields where the land is less glutted with manures are to be preferred to those grown in highly manured gardens. Hence the necessity of improving the soil by other ways than gorging it with more manure than is necessary for bringing to perfection such vegetables as are expected to be produced.

The first method of improving soils is by pulverisation, which operation is performed by trenching, digging, and ridging, the main object being to give scope for the roots of vegetables to strike out in every direction in search of nourishment, and also to promote the free circulation of air and water. Light soils in the course of time, if left undisturbed, become too compact for the free growth of the fibrous roots of plants, as well as for the proper admission of air, and water, and heat; while the strong lands, on the other hand, in a shorter time become impenetrable by the roots of vegetables. No vegetable flourishes without an abundance of roots. Therefore the soil should be adapted as much as possible to the encouragement of these necessary organs, as we are convinced that the quantity of nourishment taken up depends more on the number of absorbing fibres than the quantity of nutritious matter contained in the soil.

Digging between the rows of some plants is a matter of great importance to them, operating on the principle of pruning, cutting, and shortening the extending fibres, causing them to throw out a number of others, the plants being thus enabled to collect a larger quantity of food. It is necessary before planting or sowing that the soil be reduced to a proper consistency, and also to preserve it in that state during the growth of the plants by repeated digging or hoeings between the rows. Capillary attraction, which renders the moisture of the soil more uniform, is also promoted by digging, &c. It is very evident that those soils where the particles are the finest, such as sand, or reduced by repeated diggings or trenchings, are the driest.

Gravels and sands that are naturally reduced to fine portions scarcely retain any water, and often not sufficient for the growth of vegetables, which accounts for their unfruitfulness, while clays, if not acted on artificially, either do not absorb the water, or when they do, retain too much. It is very essential that the soil should be brought into a condition to retain a certain quantity of water and no more, as without this all endeavours to assist by means of manures will be useless.

The depth of pulverisation depends upon the nature of the soil and subsoil. In strong clayey soils it can scarcely be too deep, and even in sandy soils, provided the subsoil does not contain anything hurtful to vegetables, the admission of air is very important.

It is also necessary that all soils should be kept open as much as

possible for the admission of a sufficient quantity of heat to the roots of plants. Earths are bad conductors, and it would take a long time before the heat could penetrate to a certain depth, especially in spring, to be of any importance to roots of vegetables, unless by frequent turnings the soil is capable of admitting a free entrance of the sun's rays as well as tepid rains. It is also necessary that soils should be open for effecting those changes all manures have to undergo before they can be fit food for vegetables. Animal and vegetable substances undergo decomposition when exposed to the action of air, light, and water. Improving soils by pulverisation is very important; but still we must not think that is all, for in the strictest sense of the word it only benefits the plants by increasing their fibrous roots. Garden ground should never lie uncultivated for any length of time unless sown with grass. The aëration of lands in winter is also very important, and the water in the soil freezes, causing it to crumble down into a fine mould. Insects and their eggs, with the roots of weeds, are also destroyed in larger quantities than may be supposed.

The tenacity of clayey soils may be corrected by sand, lime, chalk, or coal ashes. Such soils cannot be too much worked; every opportunity should be taken to rough dig and ridge them, taking care such operations are not done when the soil has been saturated with wet. Soils which contain a large quantity of gravel are not quickly or readily enriched by manures, the finer portions being washed out by rain, and not being capable of retaining a sufficient quantity of moisture suffer greatly from drought in summer; but if they are cleared of a portion of the small stones and some strong loam added to form a body, they will be found capable of keeping enough moisture for the growth of future crops. Light soils, however, have their advantages, for from these we obtain our early spring crops, as they are much more capable of resisting frosts than strong soils. Being warmer they afford less moisture, and the crops do not grow so luxuriantly, and are therefore much earlier; but when summer comes they are either unproductive, of short duration, or fail altogether.

The *beau idéal* of a fertile soil, it is remarked by the late Mr. G. W. Johnson in "Chemistry of the World," is one which contains such a proportion of decomposing matter as to keep the crop growing there always supplied with it in a fit state for absorption, yet not so superabundantly as to render it too luxuriant, if the object in view be the production of seed; but for the production of those plants of which the foliage is the part in request, such as Spinach, or of edible bulbous roots, such as Onions, which have a small expanse of leaves, so as to be almost entirely dependent upon the soil for nourishment, there can scarcely be an excess of decomposed matter presented to their roots. Asparagus especially demands abundant nourishment, as, similar to the Onion, it has little foliage and fibrous roots.

But it is evident that to insure these desiderata in any soil and at all seasons is impossible, as a soil that would do in one climate would fail in another if the mean annual temperatures should differ, as well as the amount of rainfall during the same period. In the west of England we have twice as much rain as in the eastern counties, hence a soil in the east may be more tenacious and richer than the one required for the same crop in the west.

Respecting affording warmth to plants Mr. Johnson says, "The earth is of considerable importance, and the power of accumulating and retaining it varies as much in soils as the proportion of their constituents." Sir H. Davy found that a rich black mould, containing one-fourth of vegetable matter, increased its temperature in an hour from 65° to 88° by exposure to the sunshine, while a chalk soil registered only 69° under similar circumstances, but the first when removed into the shade cooled in half an hour 15°, whilst the latter only lost 4°. This explanation will show why crops on light-coloured tenacious soils are in general so backward in spring, but retain their verdure longer in autumn than those on black light soils; the latter acquire warmth more readily, and part with it with

equal speed. It may be noticed that where coal ashes are sprinkled over beds of Beans, Peas, &c., they are generally a few days earlier, as it is a well-known fact that dark-coloured bodies absorb heat more readily than those of a lighter hue.—A. G. FRAMPTON.

TUBEROSES.

WHERE buttonholes, sprays, wreaths, or bouquets are in demand few flowers are more useful than those of the single and double Tuberose. The bulbs can generally be obtained by the last week in September or early in October, and when the flowers are required early the bulbs should be potted at once and pushed forward. For succession and late flowering they can be potted at intervals of a month until the beginning of May.

An impression prevails that bottom heat is necessary for the successful culture of Tuberoses. This is erroneous, and may be the means of preventing many growing them who might readily do so in an ordinary greenhouse. Bottom heat is unquestionably a great aid where the flowers are needed early in the season, but for successional plants it need not be applied, the only difference observable is the greater length of time required before the flower spikes are visible.

The bulbs may be potted singly in 4½-inch pots, or three may be placed into 6-inch pots. Good drainage is essential, and the compost must be pressed in moderately firm. They succeed admirably in two parts good loam, the other two parts being composed of leaf soil, sand, and decayed manure. Not more than one-sixth or seventh of the latter should be used, the sand being proportioned according to the texture of the loam. During the past year our plants have been grown in soil that had produced a crop of Cucumbers with the addition of sand and one-third leaf mould. When potting is completed the bulbs must be about three-quarters of an inch above the soil, leaving plenty of room for water. There are usually a number of eyes that produce suckers and give endless trouble after they start into growth. They are quickly removed with the point of a knife, and the time required before potting is labour well spent. When they are allowed to grow they rob the plant of support that would otherwise be concentrated in the production of the stem and flowers. It is important that the soil be in an intermediate state of moisture, as the application of water is injurious before root growth has commenced.

If the pots can be plunged where the bottom heat ranges 65° to 70°, and the temperature of the structure is 60°, the plants will quickly commence rooting and growing. We prefer to cover the surface of the soil and rim of the pot with the plunging material to arrest evaporation and obviate the necessity for watering. Where bottom heat cannot be given stand them on the surface of a bed, in the temperature named, and fill the space between the pots with cocoa-nut fibre refuse, covering the surface as advised for those plunged. Bulbs started during November, December, and January may be subjected to the same treatment. Those started afterwards will do very well in warm vineries or Peach houses. It is not wise to start them in greenhouses before the beginning of March, and in all cases plunge or cover the pots to prevent the soil drying. Even in May, however, we prefer to start them in any structure where a little heat is maintained, and then remove them to cold frames or a cool house. When they are growing and rooting freely they will bear without injury the cool airy treatment of the greenhouse or cold frames where the lights can be thrown off during fine warm days. Those required for flowering during the two last months of the year may be plunged outside in a sunny position, where they can remain until the middle of September. Amateurs who have only a greenhouse would do well to pot only two supplies of bulbs—namely, on the 1st of March and on the 1st of the following month.

The bulbs potted at the present time should have the plunging material removed from the surface of the soil as soon as active growth has commenced, and supply the plants with tepid water as they need it. They can have the advantage of bottom heat until the flower spike is visible, when they may be lifted out and stood upon the surface. After they reach this stage bottom heat affords no help, for the spikes are quickly developed and commence unfolding their flowers. Arrange them as near the glass as possible to keep the foliage dwarf and sturdy. If the flowers are only needed for cutting the plants can be packed closely together without the slightest injury. Those housed about the middle of September may be placed where they will enjoy a temperature that does not fall below 50°. In this position the flower spikes will quickly appear, and the plants may be introduced into a higher temperature as required. After October they should not be in a lower temperature than 55°, which may be increased 5° to 10° by the time they commence opening their flowers. To show how accommodating

the Tuberose plant is, it may be stated that late bulbs have been stood in vineries where the roof is covered with foliage, the house has been closed only when there has been a prospect of frost, and the plants have commenced producing their spikes freely. We have kept them in this position for at least a month without the slightest sign of injury. Plants started late and grown on under glass in a sunny position frequently produce the majority of their flowers early in September. During the season of growth abundance of water at the roots is needed, in fact the soil must never be allowed to become dry. Weak stimulants, whether the plants are early or late, are very beneficial.

Only the other day we were told that the bulbs after flowering could be dried and utilised another year. Such, however, is not the case. When strong bulbs have flowered they are useless for another season. But those which fail to flower and make a good growth may be ripened, and they will flower equally as well as imported bulbs. The old plants are certainly prolific in the production of young bulbs, but so far we have failed to see that their retention for future use is advisable, especially as they can be annually purchased at very low rates. Probably also from the freedom by which they can be increased they will be cheaper in the future than they have been in the past. The variety known as Pearl is decidedly the best, but other varieties as well as the single form are by no means to be despised. The Pearl is not so tall as any other variety known to me.—NORTHERNER.

LIQUID MANURE FOR FRUIT TREES.

I HAVE rarely read an article treating of fruit trees which, especially as to those of full growth, contained such valuable advice in so few words as that of Mr. Wright in your last number. It ought not to be cursorily read and then forgotten, as is the fate of most advice of the kind, but remembered and carried into practice. Everyone whose trees are barely remunerative, especially in those districts which, less favoured than the counties of Hereford, Worcester, Gloucester, Somerset, Devon, and Kent, are not naturally well suited for growing fruit. Two conditions are eminently necessary to the perfect development of a tree: sufficient food in the soil in which it is growing, and sufficient moisture to enable the roots to avail themselves of that food.

I have reason to believe that many fruit trees have not yet perfectly recovered from the extraordinary drought of 1887-8, which had probably quite as much share as the cold and wet summer of last year in preventing the proper development and ripening of the fruit buds, which ought to have given us fruit this year. Much of the success of a fruit crop, especially of Apples and Pears, depends on the perfect growth in the preceding year of the first foliage of the tree. This did not take place in 1888, as the drought commencing in 1887 continued until June, 1888, and the soil about the roots being dust dry for many feet down full development of the leaves was impossible. The blossom buds this year were quite as numerous as usual, but very small; many of them before they swelled could scarcely be distinguished from wood buds. The blossoms were imperfect, and, notwithstanding an exceptionally favourable season free from frost, did not become fertilised and set their fruit.

The application of liquid manure in the winter of 1887 would probably have remedied much of this mischief, and the plague of caterpillars, having larger and more fleshy leaves to feed on, would have left uninjured a larger proportion of them, and the maturation of its fruit buds and the further development of the tree would have been less injuriously affected. Even in an average season the leaves of a tree prevent the greater part of the summer showers from penetrating the ground occupied by its roots; consequently it does not get as much moisture as it could use beneficially, its fruit does not swell or its growth mature so perfectly as when its full requirements are satisfied.

Fruit, especially of Apples and Pears, in the less favoured districts of the country, is comparatively small and stunted. This is obvious to anyone who at exhibitions compares the produce of the more and less favoured districts; and even as to the former, if the Apples, for example, of Mr. Bunyard, grown in his Kentish orchard, be compared with those cultivated in his orchard houses, the beauty and size of the house-grown fruit are so far superior as to give the impression that they are varieties different from the same kinds grown in the open. These various degrees in quality prove conclusively that our fruit generally is capable of great improvement, and it must be worth while to make an attempt in that direction when some of the means are so easy.

The majority of growers unfortunately are not cultivators. If they plant a fruit tree, and in fact any other tree, they leave it to take care of itself for ever after, doing nothing except sometimes in gardens where the limited space compels some pruning to keep

the trees within bounds; but some are guilty of worse than neglect, as they do not allow to a tree sufficient room to grow without disturbance. They know that a Cabbage requires a certain space for its proper growth, and do not dig or plant within that space; but they do not apply this knowledge to a fruit tree, but dig and crop up to its trunk, more especially on the borders of wall fruit trees, as they rely on these borders for their best and earliest vegetables.

The case of wall trees and espaliers is worse even than that of standards, as the extension of the boughs of the latter generally insures to them some limited space in which the surface roots are undisturbed. Nothing will compensate for destruction of surface roots, but the double-cropping of the ground renders it doubly necessary to supply by some means the deficiency of moisture and food caused thereby. Probably there is no plan more effective than that recommended by Mr. Wright; it will minimise the injury of double-cropping, and with reference to the trees which are allowed to grow naturally without interference with their surface roots, it will supply them with means of developing more perfectly both their growth and their fruit.

The food for fruit trees in any soil has its limit, which is sooner reached in the less favoured districts; but before that limit is reached there is a period during which the soil contains less than is required for healthy growth, when the trees gradually become diseased and the fruit scrubby; for this condition an artificial supply of food is the only remedy. Liquid manure combines both food and moisture, and its application in winter is more practical and effective. Practical because the ordinary work of the season does not interfere with the application being made thoroughly; and effective, because it lays up in the ground a store of food on which the tree may draw for its first and most important growth.—EDMUND TONKS.

P.S.—As the following extract from a most instructive report on "Fifty Years of Fruit Growth," by Charles Whitehead, in the forty-ninth number of the "Journal of the Royal Agricultural Society," read by me after I had written the above, bears on the subject, I venture to quote it. "In the description of fruit production in Kent it was remarked that growers had discovered that Cherry orchards require manure from time to time and were now in the habit of supplying this. This applies to other fruit orchards and to other fruit plantations to which manure is now in many instances most liberally applied. There are still growers in the cider-making counties who do not believe that the Apple and Pear trees require any assistance whatever. Generally speaking there has been a wonderful advance in this direction, which should be especially noted as constituting an element, and by no means an unimportant element, in the progress of fruit farming. It has been found that the progress of canker is stayed by plentiful manurings, and other disorders to which fruit trees are liable are checked by liberal treatment."

DESFONTAINEA SPINOSA.

IT is much to be regretted that in a great many public ornamental grounds care has not been taken to introduce our choice shrubs in larger numbers. Cemeteries give scope for a greater variety of shrubs than are often found there, and it has frequently occurred to me that no better place could be chosen for them, for many of the visitors need something that will interest and not offend them, and a more fitting object could not be found than a shrub with which the visitor is perhaps not acquainted. Laurels, Laurustinus, Lilacs, and the like, good and indispensable as they are, need not be the only shrubs planted, there being many others known and cultivated long ago that are far from being common even now. It is but seldom that the Phillyreas are met with, and no finer shrubs are grown than some of them; they always look well, and sometimes, when loaded with berries, are quite handsome. The glossy-leaved Alaternus is equally ornamental.

Desfontainea spinosa is a shrub in many respects resembling the Holly, only instead of being ornamented with berries, red or yellow in winter, it presents us in summer with an abundance of handsome orange-coloured flowers, resembling those of *Lapageria rosea*. The plant, I believe, is perfectly hardy, but ought to be classed amongst those flourishing in peat soil, more so, I think, than the *Magnolia* and some other plants. It is, nevertheless, more accommodating than some of them, and is well adapted for a low wall; but here a plant on the open lawn flowered most profusely during the past summer, no doubt stimulated to this by the weather of the previous year. With us the plant is not fast-growing, but this I attribute to the lack of peaty matter in the soil, as I have seen it elsewhere grow more freely. To those who have not seen its fine, orange-coloured, tubular flowers, and who have a favourable position for a plant of moderate growth, I would say, Obtain one of this, and the first appearance of its blossoms will be an ample reward for any trouble that may be taken.

I believe it likes a dry situation, but I am not sure of this; still, as for plants of doubtful hardiness such a position is the safest, we must take it for granted as being the best for the *Desfontainea*, until perhaps

someone finds out that one quite the contrary is better. Those places where I have seen it succeed were dry and sheltered from the coldest winds.—J. R.

THE FRUITERERS' COMPANY AT THE MANSION HOUSE.

ON Wednesday evening, September 25th, at the Mansion House, the Lord Mayor entertained the Master and members of the Fruiterers' Company, and also the members of the General Purposes Committee of the City Corporation. Before the dinner the usual presentation of fruit was made to the Lord Mayor. The fruit, the very finest specimens of English produce, chiefly comprised Pine Apples, black and white Grapes, Apples, Pears, Peaches, and Nectarines, and was artistically arranged on tables in one of the small drawing rooms.

Mr. R. S. Mason, Master of the Fruiterers' Company, addressing the Lord Mayor in the presence of the guests who arrived early, said that, in accordance with the ancient custom, the Company had the honour to present to the Lord Mayor the annual specimens of fruit. This year, in accordance with the wish of the Lord Mayor, the specimens were entirely of English growth. The Company desired through him to express the appreciation they felt of the interest the Lord Mayor took in promoting the better cultivation of choice and hardy fruit. Referring to the part the Lord Mayor had recently taken in successfully settling a labour question, he said that if the cultivation of fruit and vegetables were carried on in this country to the extent that it might be, the congestion of the labour market in the great towns would be very considerably reduced.

The Lord Mayor, in acknowledging the presentation, said he had made it known that he should prefer the gift to consist entirely of British grown fruit, because he felt there was a great necessity at the present time to offer incentives and give encouragement to the growth of fruit in this country; and he believed that if due attention were given to fruit cultivation British fruit would be as good as, if not better than, that imported from abroad. He had, as the Master had stated, in recent years taken considerable interest in the subject of fruit growing; he had done his best to persuade his fellow countrymen that it was necessary and desirable, and would be very advantageous to the community, that the cultivation of fruit in this country should be regularly and systematically extended. In the course of recent researches he had met with a successful example of fruit cultivation on a small farm not far from a large town. The area of the farm was 12 acres; and the farmer gave him figures which showed that—excluding the growth of fruit under glass—the net profit, after paying rent and other outgoings, was £137 10s. in 1887, and in the following year, when exceptional causes were in operation, it fell to £121 10s. He had no doubt that others could, by perseverance, attain equally satisfactory results. He congratulated the Company on the magnificent fruit which they were able to present under the limitation that none of foreign growth should be included.

Having accepted the fruit, H. R. Williams, Esq., Past Master of the Fruiterers' Company, then introduced Mr. J. Wright to his Lordship, at the same time explaining the object they had in view in offering a prize for an essay on fruit, to which Dr. Hogg kindly added a gold medal as an incentive to competitors. Sixty persons, he said, applied for the particulars of the competition, but only fourteen sent in essays, the number, he suspected, being limited because of the stipulation that each competitor was required to make a declaration to the effect that he had at least ten years' actual experience in the cultivation of fruit, and to indicate where the experience was obtained. Mr. Williams observed that this stipulation would naturally restrict the number of essays, but correspondingly increase their value. Most of them, he had been informed, were of great merit, but the prize was unanimously accorded to the one sent in by Mr. J. Wright. This he had seen, and was highly satisfied with it, and believed it would be largely circulated and do much good. He expressed his pleasure in finding that the successful competitor was on the staff of Dr. Hogg's Horticultural Journals. This, he thought, must be gratifying to Dr. Hogg, and would inspire public confidence in those Journals and the advice and instruction they contained. Mr. Williams further added that Dr. Hogg knew nothing whatever about Mr. Wright's action in this matter. He was not apprised of the existence of the essay till it was completed and sent in. He had never seen it, and only learned the decision of the Judges by announcement in the usual way. He then produced the prizes for formal presentation.

The Lord Mayor immediately handed them to Mr. Wright, with, as he said, very great pleasure indeed. He had had the opportunity of glancing through the essay, though he had not had time for reading it carefully and critically. He was satisfied, however, it was a valuable contribution on the important subject of fruit production, and asked of the author the acceptance of his sincere congratulations. He (the Lord Mayor) as was known, took great interest in the home culture of fruit, and strongly desired to see its development; and he felt sure that the action of the Fruiterers' Company would contribute powerfully to that object, that the essay, he believed, pointed the way clearly, and he therefore held out the right hand of fellowship to Mr. Wright, whom he trusted would see good results from the work he appeared to have done so well.

The medal has a handsome ornamental border of Apples, Pears, Grapes, and various other fruits entwined, while the centre bears the words:—"Presented by Robert Hogg I.L.D., F.L.S." On the reverse

side is the following inscription:—"To Mr. John Wright, the successful competitor for the prize of 25 guineas offered by H. R. Williams Esq., P.M., through the Worshipful Company of Fruiterers, for an essay on Profitable Fruit Growing for Cottagers, 1889."

Mr. Wright, in acknowledging the honour conferred, said that it was greatly enhanced in value in having been received at the hands of the chief magistrate of the city of London, whom he thanked for his kind words and for his services in the cause of fruit culture in this country. Mr. Wright hoped the essay contained plain teaching that might be understood by the inexperienced who needed instruction. It was founded entirely on practice, and methods of procedure were made as clear as he could make them with pen and pencil. He had long felt humiliated when he visited, not large cities alone, but particularly the markets of small towns in agricultural districts, and found barrels of foreign Apples everywhere, while the surrounding land would grow even better samples, if the varieties were wisely chosen and well grown. He was glad to see the revival in fruit farming, but particularly desired to see, as he believed the Lord Mayor and company assembled desired to see, the greatest possible number of the industrial population who had gardens attached to their cottages, or suitable plots of land, devote a portion of them to the cultivation of fruit for their families, disposing of the surplus in adjacent towns. He believed in this way the condition of many of the toiling masses might be improved, and the greater the contentment in the homes of the multitude the greater would be their loyalty to the throne and constitution.

The room was crowded, and among the horticulturists present were Dr. Hogg, Rev. W. Wilks, and Messrs. T. Francis Rivers, A. F. Barron, Shirley Hibberd (the three last named being the adjudicators in the competition), R. D. Blackmore, Harrison Weir, and G. Bunyard. Those gentlemen, with the Very Reverend Dean Hole, Mr. Thiselton Dyer, Mr. Wright, and nearly three hundred others, subsequently dined with the Lord Mayor and Fruiterers' Company in the Egyptian Hall.

At the Banquet numerous toasts were proposed and honoured, and the Lord Mayor, in proposing the "Fruiterers' Company," said he had made the gathering at the annual presentation of fruit larger than usual because the Company had recently shown great interest in fruit culture. He believed their chief aim was to bring about the re-creation of homestead and cottage orchards. In all our counties, with perhaps three exceptions, there were in years gone by orchards which produced good and marketable fruit; and these orchards were now worn out, or were decaying and not being renewed. This was a disgrace to our country, which was as capable of growing fruit as America or Australia. There must be something wrong to account for this condition of things. Some evils were of a more or less controversial character, and that was not the place to discuss them; it was not sufficient for him to acknowledge the admirable action of the Fruiterers' Company in doing their utmost to promote the growth of hardy fruit in this country. The success of those efforts would improve the condition of the agricultural population, would keep population in this country, would relieve the glut of the labour market in towns, and so would benefit the whole country. The Company was therefore entitled to gratitude for the efforts they were making to extend fruit cultivation. The present Master of the Company had shown greater aptitude in this work than any of his predecessors; he was seeking to raise a sum of £5000 to carry on the work, and the Company was determined to go on increasing its usefulness from year to year for the benefit of the country at large.

Mr. Mason, in responding, said it was quite true that within the last year or two the Company had made great efforts to spread amongst their countrymen some knowledge of fruit farming; but he found it almost impossible to speak upon a subject which was difficult, endless, and controversial. He was constantly appealed to by would-be fruit growers for information upon a great variety of questions, and he could only refer them to the records of the conferences that had been held, and practical papers in the class journals. The appeal of the Company was to be brought before the Corporation, who no doubt would respond liberally; and Mr. Chaplin, he hoped, would be able to do something for them in his new office. They were under obligations to the Lord Mayor for the interest he had taken in their movement.

ANNUALS FOR MIXED BORDERS.

THESE make a display through the summer months with very little trouble, and deserve to be grown much more extensively than they are at present; some of them being seldom seen, causing numerous inquiries how they can be obtained from ladies who see them growing. In many instances they have acquired an uneventful reputation where they have been grown, either because seed was not sown early enough or the ground was too poor for them, but with a little care they assist considerably in adding interest and beauty to the mixed border and similar positions, and as a rule continue in flower much longer than the ordinary occupants. In order that some of them may reach their full development next summer they should be sown at once in a warm and sheltered position in rows about 1 foot apart and covered very slightly, to remain in this position during the winter and be planted in their permanent positions at the end of March or early in April, according to the season. The following are quite hardy here:—*Nemophila insignis*, *Leptosiphon hybridus*, *Centaurea cyanus minor*, *Eschscholtzia erocea*, *E. Mandarin* and *E. grandiflora rosea*, *Clarkia integripetala* and *C. pulchella marginata*, *Matricaria inodora flore-pleno*, *Xeranthemum annuum flore-pleno*, Sweet Peas, *Papaver umbrosum*, *Erysimum Perofskianum*, &c.

Several others are hardy farther south, but will not survive an

ordinary winter here, and we therefore sow them early in spring—about the last week in March or as soon after as the weather permits, except a few of the tenderest of them, which are marked with an asterisk, and should be sown a fortnight later than the others. *Malope grandiflora*, *Linum grandiflorum*, **Phacelia campanularia*, *Cacalia coccinea*, **Cosmos bipinnatus*, *Nigella damascena*, **Eutoca viscida*, *Convolvulus triolor* (mixed), *Chrysanthemum segetum*, **Ipomæa purpurea* (mixed), **Anagallis* (mixed), **Brachycome iberidifolia*, **Dianthus Hedderigi* and **D. laciniatus*, *Godetias* in variety, *Schizopetalon Walkeri*, *Whitlavia grandiflora*, Sweet Sultan, yellow, red, and white, *Bartonia aurea*, and many others. These should be sown in clumps where they are to flower, thinning them out to about six plants as soon as they are ready. In most instances no further attention will be required beyond keeping them clear of weeds.—W. H. DIVERS, *Ketton Hall, Stumford*.

LÆLIA PUMILA.

THIS is a beautiful, but at the same time, a very variable species; the white marginal border to the lip, however, is always present, let the variations be ever so great in other respects. It thrives best when placed upon a block of wood and treated like *L. præstans*. The rhizome is creeping, not much stouter than a goose-quill. Pseudo-bulbs are approximate, oblong, 3 to 4 inches high, slightly furrowed; leaves solitary, oblong, lanceolate, acute, coriaceous, and bright green; scape one to two flowered; flowers large and spreading, upwards of 4 inches in diameter; sepals oblong-acute, the dorsal sepal recurved; petals more than twice the width of the sepals, and like them of a deep purplish lilac, in some varieties approaching rosy crimson; lip three lobed; lateral lobes large, incurved, enclosing the column, white, blotched with purplish crimson near the edges; mid-lobe roundish, flat, deeply emarginate, deep crimson with a distinct marginal border of pure white. It blooms during September and October, and is a native of Brazil. 1843.

LÆLIA CINNABARINA.

A dwarf compact growing plant, producing flowers of great beauty, the fact of their peculiar colour being very rare amongst orchidaceous plants rendering them all the more valuable; Pseudo-bulbs pyriform or flask shaped, tapering towards the point into a slender neck-like stem 4 to 5 inches long, dark green tinged with reddish brown; leaves solitary (more rarely in pairs), oblong, acute, erect, very thick and leathery, 5 to 6 inches long, deep green; scape much longer than the leaves, many flowered; sepals and petals equal, linear lanceolate, deep reddish orange; lip three-lobed, the mid-lobe spreading, lateral ones enclosing the column, the same colour as the perianth. It blooms during the spring months.

LÆLIA FLAMMEA.

Another of the Messrs. Veitch's hybrids, and in this case we are again indebted to Mr. Seden. "Imagine a flower of *Lælia cinnabarina* increased three times, with its brightest vermilion; give it a splendid yellow lip, with an amethyst-purplish wavy anterior lacinia, and a small white column washed under the stigma with purple; thus you have the first rank beauty, raised by Mr. Seden at the Royal Exotic Nursery of Messrs. Veitch." Such is Prof. Reichenbach's description of this beautiful hybrid Orchid, which, on account of its uncommon and effective colouring, is one of the most welcome. It was raised between *Lælia cinnabarina* and *Lælia Pilcheri*, itself a cross-bred plant between *L. crispa* and *L. Perrini*. It was described by Mr. T. Moore as follows:—"The plant is of moderate stature, and has slender cylindrical stems, each terminating in a solitary ligulate, oblong, fleshy leaf. The peduncles are terminal, somewhat elongated, and bear one to two flowers, possibly more; the individual flowers are some 4 inches across, with ligulate acute sepals and petals, of a brilliant cinnabar-orange colour, while the lip, which is oblong and trifid in front, has the yellow side lobes folded over the columns, and the intermediate one rounded, denticulate, somewhat crisped, and of a rich crimson hue, passing into crimson veins on the disc." It blooms during the spring months.—G. T.

SHADING ORCHIDS.

WHERE shading has been practised as little as possible during the past month the blinds may be removed and stored during the winter. If no attempt has been made to prepare the plants for full exposure the change will be too sudden, and it will be better to continue the use of the blinds for a few weeks longer, employing

them as little as possible before removing them altogether. It will still be necessary to shade *Phalænopses* from bright sunshine for some time yet, and the blinds may be drawn down on the south side of the *Odontoglossum* house for a few hours when the sun is hot. If the structure in which they are grown runs north and south it will be necessary to use the blinds on the west side only. Full exposure from the present time will do the plants no harm, and the use of the blinds for a few hours is only advised on the ground that it prevents the temperature rising too high and the atmosphere of the house drying quickly through a high temperature and abundance of air. Overshading cannot be too strongly condemned, it results in long soft foliage that will scarcely support itself. Good flowers and stout spikes cannot be expected from plants in this condition. The finest flowers, with good substance and highly coloured, may be looked for from plants that have sturdy well ripened pseudo-bulbs and foliage that turns nearly red by gradual and careful exposure to light.

WINTER BLINDS.

These are of the utmost value for covering Orchid houses during the winter. They protect plants that may be arranged in baskets or on blocks close to the glass, and assist wonderfully in maintaining a uniform temperature about the plants. The hot dry heat that has to be maintained during very windy weather proves injurious to these plants, but is largely overcome by the use of strong canvas blinds for covering the roof. However well houses may be glazed or supplied with pipes, it is difficult in windy weather to maintain the requisite temperature without overheating, and any system that will obviate this is worthy of consideration.

CATTLEYA TRIANÆ.

In many gardens these cannot always be given the exact temperature in the various stages of growth that will suit them best. It often happens that they have to be grown slightly warmer than is good for them in order to suit other plants. Those that have made their growth and produced their flower sheaths are very liable to start again into growth. This must be prevented, for growths that are made during the dull sunless days of winter are only puny in comparison with what they should be, and the next season's growth is often considerably weaker than it would have been had winter growth been prevented. Where plants may have started into growth nothing is to be gained by starving them; on the contrary, the growths started may damp and the plants next spring will be compelled to force dormant eyes into growth, which rarely make growths as strong as those from the leading pseudo-bulbs. The best course with those that have started is to move them to the warmest structure, say the East Indian house, and thus assist them to make and complete their growth as early as possible. To prevent growth no harm is done to the plants by removing them to a cooler and more airy structure, fully exposing them to the sun. The temperature should not fall below 50°, and the plants must be carefully watered at their roots but not allowed to suffer by keeping them too dry.

MILTONIA CANDIDA.

This is a strong growing Orchid, and flowers with great freedom when grown at the coolest end of the *Cattleya* house and exposed to plenty of light during the latter stages of growth. It does well in a pot with fibry peat and a good layer of sphagnum moss on the surface. It flowers so freely that pseudo-bulbs of moderate strength only will produce two spikes, and often three and four. It is useful, flowering as it does during September. The supply of flowers may be prolonged considerably where a number are grown by pushing some forward at the warmest end of the house, and retarding others by growing them at the coolest. The form of this Orchid known as *grandiflora* is unquestionably the finer of the two, being of stronger growth with larger and brighter coloured flowers, but it is a rare plant in comparison with the other. It flowers at the same time, and grows luxuriantly with the same treatment.

MAXILLARIA PICTA.

Where sweet Orchids are appreciated this is well worth growing. For some years we have had some in 5-inch to 7-inch pots for placing, when in flower, in vases in dwelling rooms, and the flowers for cutting for filling small glasses. The plants bear confinement in rooms without the slightest injury. Our plants make their growth in the *Cattleya* house, and are then placed at the coolest end of the *Odontoglossum* house and fully exposed to the sun. From this structure they are removed to heat as required. It is a free growing Orchid and increases rapidly. It grows well in peat, and only needs a complete rest after the completion of growth. The plants are also allowed to rest again after flowering. Their removal from a warm house to a cool one after flowering appears to do them no harm.—ORCHID GROWER.

THE ORANGE-COLOURED SATYREUM.

TERRESTRIAL Orchids have with a few exceptions been somewhat neglected by cultivators, and it is satisfactory that some species are being again brought into notice. Upon several occasions during the past season plants or flower spikes have been exhibited at the Westminster meetings, and one for which a certificate was

FIG. 36.—SATYREUM AURANTIACUM.

granted—namely, *S. carneum*, has already been figured in this Journal. Another shown by Mr. T. S. Ware under the name of *S. aurantiacum* is now represented in fig. 36, and though somewhat smaller and less imposing than the one previously noted, it is decidedly attractive. The leaves are broad, the flower spike

compact and long, the flowers being of a rich orange colour. It succeeds with the same treatment as the other species from the Cape of Good Hope.

THE CHISWICK VEGETABLE CONFERENCE.

LAST week we gave a summary of the Exhibition, and referred to the papers announced in the programme to be read on Wednesday and Thursday, September 25th and 26th. We are now able to publish abstracts of some of the principal contributions, with a list of the awards made by the Committees of Selection.

The proceedings commenced on Wednesday, at 2 P.M., by an opening speech from the President, Sir Trevor Lawrence, Bart., M.P., who complimented the exhibitors on providing such a representative display of horticultural produce, and on behalf of the Society he extended a hearty welcome to the horticulturists present. He considered it was most desirable, in the interest of the community, that more vegetables should be eaten, for although he was not a vegetarian, he was assured that if more good vegetables and less beef and mutton were consumed, a great improvement would be effected in the health of the people. He also suggested that attention be paid to the preservation of vegetables in this country. It is at present neglected in England, and if he wanted preserved vegetables he had to obtain supplies from abroad. He hoped that much would be done to bring into greater prominence the best varieties in the several sections, and also that attention might be directed to several really good vegetables but little grown. He mentioned the Turnip-rooted Celery and Cardoons as worthy of more general attention. With regard to improvement in the cooking of vegetables, he appealed to the ladies present to do all in their power to effect a much-needed reform.

Mr. H. J. Veitch followed with an address on the improvement amongst vegetables during recent years, in which he remarked that though vegetables are not so important for exhibition as ornamental plants, flowers, and fruits, they are full of interest to the gardener, for to their production he had necessarily to devote a large share of his attention. He said Cabbages were generally grown throughout Western Europe 2000 years ago, and that the evolution of the numerous and widely diverse members of the Brassica family from the wild form represented a very long period. The Potato, introduced about 200 years ago, had undergone a great improvement, and it was probable that still further improvement might be effected by intercrossing. Of late years a considerable change had been made in Potato culture, and now the importance of a change of seed and a thorough tillage of the soil are fully recognised, with the result that the losses from disease had been much reduced. Of Peas in the lists twenty-five years ago about 100 have disappeared, the most important of the old varieties remaining being *Ne Plus Ultra*, Veitch's Perfection, *Champion of England*, and *British Queen*. The sorts which had disappeared were replaced by improved varieties, of which forty-two had after trial been certificated by the Royal Horticultural Society. These are undoubtedly superior to the older sorts. Beans also had materially improved, and he mentioned several as valuable additions. Several Butter Beans have been introduced, and he considered they deserved to be more generally grown, for when served in accordance with the practice which obtains on the Continent they are delicious. Carrots, Turnips, and Radishes were noted, and Mr. Veitch observed that the cultivation of Mushrooms had been so greatly increased during the past thirty years that to every pound then grown at least one ton is now produced. If there had been activity in the introduction of new sorts, the manufacture of new names had not been neglected, and the Royal Horticultural Society have been fully justified in making their comparative trials for the purpose of bringing more prominent into notice the finest kinds, and reducing the names both in gardens and catalogues. He hoped that gardeners would in all cases support the authority of the Society by adopting its recommendations in the matter of nomenclature.

The next paper was by Mr. Hibberd, and was followed by an interesting discussion in which Sir Trevor Lawrence, Mr. H. J. Veitch, and Mr. H. de Vilmorin joined.

CULTIVATION OF ASPARAGUS.

[Abstract of a paper read by Mr. Shirley Hibberd.]

IN a brief essay on this subject Mr. Hibberd said he had no intention of touching those points in the cultivation of Asparagus that were generally understood, but some exceptional matters, the consideration of which his own circumstances had forced upon him. The actual necessities of his domestic life during a series of years included a continuous supply of Asparagus for the table. To be without this vegetable for two or three months together had been to him so serious a matter that he was bound to adopt measures to bridge over the hiatus; moreover, he had been compelled to produce a continuous supply on a heavy clay soil altogether unfit for the purpose. He had been enabled to secure any necessary amount of rubbish from the demolition of buildings, the usual cost of this material being 1s. per cubic yard, with a trifling gratuity to the carters. When roughly turned over in the yard there was obtained a great bulk of broken lime and plaster, and this being mixed with decayed vegetable rubbish and the top spit of turf from the clay pasture to be operated on formed the material for the Asparagus beds. The beds were formed by simply depositing the mixture on the surface, and thereby forming banks 2 or more feet deep and 6 feet wide, and the

rule had been observed of growing on these rough beds a quick green crop of Potatoes the first season. The preparatory crop being removed, and the beds dug over and liberally manured, they were sown with Asparagus in rows 2 feet apart, after which the beds were cut down to a reasonable width for two rows of plants, and these as they advanced were thinned in the rows to 2 feet apart. In hot dry summer weather irrigation was practised, and great care was taken to keep down weeds and to ensure that only one stool should be formed at each station at 2 feet distance every way. The growth of the plant was vigorous; in due time the supplies were liberal; and usually a fair supply of table grass was obtained agreeably to the primary requirement of a continuous supply.

Certain rules observed in this culture were set forth, comprising first a conservative system of cutting; the removal of sprue not being allowed, and only so much of the "fat grass" being taken as was actually wanted. This treatment favours the accumulation of vigour in the plant, which is favourable to continuity of supply and the production of a fine sample. Another point of importance is to afford shelter in spring when growth commences by sprinkling light litter on the bed. The grass rises more freely when thus aided, and on occasions of sharp frosts in the month of May, loss by the freezing of the pushing points is avoided. Another system of shelter is secured by leaving the straws on the bed wholly untouched until the autumnal growth is stopped by frost, when the beds are cleaned and a good dressing of half-rotten stable manure is put on as a finish.

Mr. Hibberd insists on the presence of lime in considerable proportion in the soil as essential to a fine growth of Asparagus. He condemns the cutting of sprue as a wasteful weakening of the plant, and as explaining the often poor quality of the Asparagus grown in English gardens. He placed before the meeting samples of several qualities of growth from 3 feet, with a circumference at the base of the straws of 1½ inch to straws of 7 and 8 feet with a circumference of 2½ to 3 inches; this growth being entitled to the name "giant" Asparagus. As regards varieties, however, he insists there is but one, and it is impossible there should be more so long as the plant is grown from seed; the visible variations, therefore, must be attributed to local circumstances of soil, climate, and cultivation.

On the subject of an autumn supply we were warned in a general way it was not to be looked for, and perhaps was not often wanted. In his case a great supply was not needed, but a continuous supply was of the utmost importance. He had therefore set apart a sufficient extent of plant for the autumn cutting, and from the beds so reserved not a single head was cut of the spring growth. A free early growth was the natural result, and this ripened off early, and then the plant would take a rest. By means of irrigation in July and August a new growth was obtained, and this in a favourable season would continue until about the 8th of October, when frost would put a stop to it. But in the least favourable seasons the supply during August and September was often not far short of what the same beds would have produced in spring had they not been reserved for this special purpose. He placed upon the table a nice sample of table grass, the heads measuring 6 to 9 inches in length, and 1½ to 2 inches in circumference, with an abundant proportion of tender green top. Such Asparagus he averred was delightful eating with grouse or partridges, and probably in the more favourable parts of the island a supply might be secured even for an accompaniment to pheasants. His experiences had been acquired on the cold clay soils of the northern suburbs of London, and during some part of the time in the valley of the Lea, where frost and fog are frequent destroyers of garden produce as late as the end of May, and as early as the middle of August. Being exposed also to strong gales he had found it necessary to support his Asparagus with stout stakes such as are employed for the support of tall Peas. These are driven into the ground in such a way as to prevent the breaking of the straws, which would otherwise happen in a strong wind.

Not a word was said by the author about the relative values of English and French Asparagus, but from the beautiful examples of table Grass Mr. Hibberd displayed before the meeting it was evident that his taste inclines to the English custom of securing a green top full of flavour in place of the white Grass that is comparatively flavourless, though in such general esteem on the continent of Europe. It is something to see Asparagus equal to that of average growth in June, cut after a frost of 10° has given new colour to the woodlands at the close of September.

Mr. G. Norman's paper on Winter Salads was brief and practical. Lettuces and Endives receiving especial attention, and a vote of thanks to him concluded the first day's business.

Upon Thursday Mr. Shirley Hibberd presided, and there was a good attendance of Fellows and visitors. The first paper was that by Mr. J. Wright, which evoked considerable discussion of an instructive character, and it was followed by papers read by Mr. A. Dean, Mr. T. Laxton, and Mr. J. Smith of Mentmore, abstracts of the three first named being appended in the order they were read. The proceedings of this most satisfactory Conference were terminated by the customary votes of thanks to the Chairman and contributors of papers.

THE FOOD OF VEGETABLES.

[Abstract of a paper read by Mr. J. Wright.]

AFTER alluding to the unprofitableness, for purposes of utility, of vegetables of enormous size, and giving a striking instance of the hoe as a creator of wealth, dwelling on the importance of turning the virtues

of the atmosphere to the best account by good tillage, giving an example of nutritious vegetation and the reverse, as influenced by manures in Dr. Hogg's pasture as determined by the cows choosing one portion and rejecting the other, Mr. Wright said:—

But what is manure, or the ingredients which crops abstract, and which, as Liebig says, are "lost for ever," if not replaced by man? What are known as natural or animal manures employed in cultivation are obtained from vegetables, which, as Johnston says, contain "ready formed, that is formed during their growth from the food on which they live, phosphate to form the bone, gluten to form the muscle, oil to produce fat." Now if the food referred to is defective in the requisite constituents so must the animals be, and so must be the resulting manure. Such is the fact, and it is impossible to get nourishing food out of vegetables that do not contain it, as they cannot if it is not in the soil, but as they certainly will if it is there and within their reach.

Some persons condemn natural manure and extol the so-called artificial; others condemn the artificial and extol the natural. I think it is better to do neither, but to discriminate. Ville, the great French chemist, says land to which farmyard manure only is applied is being gradually exhausted, and that its fertility can be better maintained and crops better fed with the three ingredients—lime, potash, and phosphoric acid in combination with nitrogenous manure. Professor Wrightson says farmyard manure has no equal. Stephens, in his "Book of the Farm," says a ton of first-class well made manure should contain between 12 and 14 lbs. of nitrogen; 11 to 15 lbs. of potash; 8 to 9 lbs. of soluble salts of phosphoric acid (as in superphosphate); and 10 to 13 lbs. of insoluble phosphate, as in bones. As these are all the ingredients Ville asks for, and as the manure also acts mechanically in opening the soil, supplying silica, and eventually humus—which is the nursery of Bacteria or micro-organisms that render the nitrogen active by converting into nitrates—such a mixture of good things must be long in exhausting the land. It will feed the land and the crops; but—and here is the point—not one ton of manure in ten thousand equals, or even approaches, the standard named. The bulk of the material that gardeners have to work with does not half equal it, and a vast quantity is but a poor apology for the genuine article—the husk without the kernel, a dead body from which the spirit has gone.

Then come the value and the need of the concentrated essences known as artificials. Every gardener should have a supply of these, and he may then not only increase the produce of the soil, but improve it—storing the vegetables with food, without which, though they may be passable, they cannot be perfect. Phosphoric acid with potash, the former predominating, for the Brassica family; potash with phosphates for the Legumes or pod-bearers, also Potatoes; and nitrogen for every crop that needs a whip on to enable it the more freely and fully to abstract the substantial ingredients. With superphosphate of lime, chloride (or nitrate) of potash, the latter the more potent and costly, also nitrate of soda or sulphate of ammonia at hand, the gardener can improve his probably poor farmyard manure considerably, and indeed need not wait for it as so many men have to do till they lose their tempers and prejudice their crops.

When special manures are found to be good they contain the above named ingredients, and possibly others, which may act beneficially in certain soils; thus magnesia for Potatoes, soda for Asparagus and Carrots, and chlorine for Beet (both imparted by common salt), and a little iron for most crops. According to the experiments of Dr. Griffiths, principal of the Lincoln School of Science, many soils do not contain sufficient of this ingredient. His "Treatise on Manures," which is an admirable work, contains striking examples of half cwt. of iron sulphate (green vitriol) per acre increasing the crop of Potatoes, Turnips, Mangolds, Cereals, and Beans, while it cured the stubborn root disease of Cucumbers (according to the evidence of Mr. Crocker, of Ham Green Tomato fame), and gave him extraordinary crops. Passing for a moment from vegetables, Mr. Divers has recently stated in the "Gardeners' Chronicle" its efficacy in curing a fine Peach tree of yellows. I have seen the tree, and can pronounce the cure complete. For vegetable crops about a quarter to the square yard will suffice for experimental purposes, either in solution or powder, this to be applied only when the soil is wet to yellowish-looking plants and crops for producing colouring matter or chlorophyll.

But while the soil must be fed for feeding the crops it is possible to impair its productiveness by over-manuring, especially with matter from stables of milking cows, and decayed leaves. I once took possession of a garden that was like a mass of humus, through additions of that nature for generations, perhaps. A walking stick could be pushed down it to the handle easily. One plot, I was told, would grow Potato plants, but no tubers. I found that to be a fact, and recorded it in the *Journal of Horticulture* at the time. Peas were yellow and profitless. The soil was poisoned with acids, and lime was needed to neutralise them, also to set free the dormant nitrogen. It was given freely, as also was potash and bone meal. The effect was magical, and the crops of Potatoes and Peas, where they would not grow before, were remarkable. Why were potash and phosphates so much needed? Because there were none in the cowyard manure. The phosphates were drawn away with the milk. Manure from milch cows, especially if largely fed on grass and roots, is greatly over-estimated. There is little good in it to feed crops. It may make them grow, but the growth is comparatively worthless. Proof of this can be found in any cow pasture where the manure is not spread. The grass grows freely enough, but the animals refuse to eat it, and eventually tussocks form and pastures are spoiled. Manure from full-grown well-fed bullocks is very different,

for it is rich in phosphates and other nutritive or manurial properties. It is well then, as I said before, to discriminate.

If weak manure is supplied to the garden, and I have often had it so weak that it would not ferment when moist, mix half a peck or more of good guano in a load. The mass will soon heat then, and eventually its value for the land will be a good deal more than doubled. Instead of conflict between natural and artificial manures we then have combination, and the union is a happy one for whatever crops are fed with the preparation.

In conclusion the lecturer remarked:—Quick-acting nitrogenous manures, such as nitrate of soda and sulphate of ammonia (the former for light and dry, the latter for heavy and cold soils), should be applied early in the season to growing crops, never late in the autumn; phosphatic and potassic manures earlier still, before growth commences and before dry summer weather sets in, or they cannot be appropriated, because not dissolved, by the crops they are intended to support. Chemical manures have often been condemned as worthless, when the fault rested with the users in simply applying what was really good at the wrong time for attaining the object in view. These remarks are founded on practice. I think they cannot do harm to any, and may possibly be suggestive to some who may engage in the cultivation of food-producing crops.

POTATO IMPROVEMENTS DURING THE PAST TWENTY-FIVE YEARS.

[An abstract of the paper read by Mr. A. Dean.]

TWENTY-FIVE years ago we had no great wealth of variety in the Potato, and it is a significant fact that, with the exception of the Ashleaf Kidney, a sort which has kept its place chiefly because hitherto there has been a lack of first early varieties, there is hardly to be found in seed Potato lists one then in ordinary cultivation. It is still very much the fashion on the part of those who sigh after the days and years that are gone to declare that none of the modern Potatoes equal in quality the Regents, Lapstones, Fortyfolds, and other sorts of the past. We have had since the date I refer to myriads of good Potatoes introduced and plenty of bad ones. We have myriads of good Potatoes now also, and a far less number of bad ones, and we have at least an abundance of varieties which, whilst equal in quality to the best of bygone days, do by far excel them in robustness and productiveness. The Potato really has improved—the eaters of them have become less capable of appreciating them.

Then there has been no inconsiderable improvement in form and beauty. Those who saw, and remember, the singularly beautiful tubers shown at the various exhibitions held under the auspices of the International Potato Show Committee, must admit that in development of form wonders have been worked during the past twenty-five years. "But," exclaims the Potato pessimist, "beauty of form and smoothness of skin is no evidence of quality!" Perhaps not; but, on the other hand, neither is ugliness. If we have had some beautiful Potatoes of bad quality we have also had myriads of good ones, and the efforts of the International Committee were specially directed to the elimination of the bad and the expansion of the good, not only at the Crystal Palace, but through the Royal Horticultural Society in their gardens also. Form and beauty, beyond satisfying the requirements of the cultivators of refined tastes, have become marketable commodities also, for the handsomest samples always secure the best prices.

One of the chief factors in Potato development during the time previously named, however, was found in the introduction of American varieties. These came to us in myriads, generally characterised by similarity of appearance, but varying perhaps in colour. All were remarkable croppers, and if few possessed high quality or flavour, yet all did materially help to swell our Potato supplies. How many of these varieties introduced at the time with much flourish of trumpets have now gone to the eternal Potato bourne our lists of to-day will serve to show. Just one or two remain to us in their natural form and goodness, chief amongst which is the favourite Beauty of Hebron; the best perhaps, as it has been the most permanent of all the family. But our home raisers awakened to the need of doing something to counteract the flooding of our trade with American sorts, and further, alive to the value of these strangers as parents of better strains, they utilised the best for seed-bearing purposes, fairly skimming the cream off them and casting the residue aside as worthless.

Our esteemed friend, Mr. Robert Fenn, who had at Woodstock been raising varieties which were perfect in quality, but lacking in robustness and productiveness, was one of the first to utilise American varieties as parents. Many others presently followed suit, with the result, briefly put, that dispensing with all old sorts, and nearly all American varieties, we have a race of Potatoes which is productive, robust, gives good quality, and supplies the tables of the poorest in the land cheaply and abundantly. But apart from the Americans, which in spite of their comparative robustness still succumbed wholesale to the deadly effects of the *Peronospora*, there was this very fungus with all its dire destructiveness constantly forcing upon Potato men the need for battling with it for the preservation of our Potato stocks. It is idle to regard it as other than a terrible and a disastrous visitation, and in years past when we had none other to depend upon but Regents, Fortyfolds, Victorias, and similar tender though delicious varieties, there was at times reason to fear that the Potato crops of the kingdom would be absolutely decimated.

One of the first products of the Anglo-American Potato crosses was that famous variety, *Magnum Bonum*. Its history is pretty well known;

but in referring to the improvements in Potatoes during the past twenty-five years it would be impossible to omit reference to a variety which has proved to be so important a factor in the work of disease-resisting, and practically of conquering. Raised from the seed produce of the Early Rose, assumedly crossed with the Victoria—a once famous Potato, but now rarely met with—by Mr. Clark of Christchurch, it became so widely known and grown in a few years that probably it made more noise than any other Potato ever introduced to commerce. Fortunately for Mr. Clark and the community tubers of it and other varieties were sent to that once famous trial ground at Stoke Newington, over which Mr. Shirley Hibberd was the presiding genius; and so much was that gentleman taken with the variety that he introduced it to the Messrs. Sutton & Sons of Reading, who purchased the stock.

But even in raising a variety which presented so formidable a barrier to the progress of Potato disease there were not wanting critics who railed at its quality. If half a loaf be better than no bread surely a whole one is better still, and that much did Magnum Bonum give to myriads of Potato consumers, to whom in previous years the tender old kinds of Potatoes, under the deadly effects of the disease, gave no loaf whatever. It is, however, worthy of remark that in spite of the critics the Magnum Bonum is more largely eaten now than any other Potato. But having found so admirable a barrier against the tide of fungoid decay, raisers have not been slow to take advantage of it for the purpose of producing many other disease-resisting kinds, and possibly of much superior quality. We have now not one but a wealth of disease-resisters, and because of them have such an abundance of Potatoes that they can hardly be disposed of at any price. Really the salvation of the Potato and of the consumer has been the ruin almost of the trade, for with stocks so plentiful few want to purchase, and trade is almost unprofitable to growers.

Why, in the old disease days, before Magnum Bonum and other fine sorts came to our aid, we imported thousands of tons of Potatoes during the winter months from Germany, Belgium, and elsewhere. That trade has been entirely suspended, for the excellent reason that we grow plenty of Potatoes at home, not only for our consumption, but have an abundance to spare. It is true we import large quantities of early Potatoes from France, the Channel Islands, &c., but their consumption in preference to good home-grown old tubers displays a sadly vitiated taste, as in most cases they are more fit for pigs than for intelligent men. Mr. C. Fidler of Reading has informed me that the average price of Potatoes now in the market is fully thirty to forty per cent. lower than it was ten years ago, a fact which speaks volumes for the wonderful development of Potato production, the result of the possession of numerous disease-resisting varieties.

The following list of sorts affords some evidence of the change which has been effected in Potatoes within the past comparatively few years:—Beauty of Hebron and its white variety, Webber's White Beauty, a distinct early sort; Sutton's Early White Kidney, Seedling, Satisfaction, and Abundance, all robust and great croppers; Snowdrop, Schoolmaster, Magnum Bonum, Vicar of Laleham, The Dean, Reading Russet, Prime Minister, Chancellor, Reading Giant, White Elephant, Imperator, The Daniels, Lye's Conqueror and King of Russets, The Governor, The Bruce, Stourbridge Glory, and many others, nearly all great croppers, and creators of that wealth of Potatoes which contrasts so wonderfully with the comparative dearth of twenty-five years since.

IMPROVEMENTS AMONGST PEAS.

[Abstract of a paper read by Mr. Laxton.]

MR. LAXTON contended that, during the past quarter of a century, great improvements had been effected, especially in the directions of earliness, of handsome, large, and well-filled pods, and of dwarf later sorts, but that there is scope for further advance in fertility and hardiness, more particularly in the production of hardy market varieties; and he holds that continued and constant attention will ever be necessary to maintain the acquired earlier and dwarf characters of Peas, as the stocks are especially liable to deteriorate in these respects, chiefly from repeated shelling out previous to and in harvesting, and the destruction by birds, &c., of the earliest and dwarfest portions of the stocks before the bulk can be secured. Mr. Laxton also alluded to the two modes of improvement resorted to by growers—selection following natural or insect cross-fertilisation, which, contrary to the general belief, he considers does take place, although rarely in the Pea, through the instrumentality of thrips and similar small insects, and that the presence of "rogues," as the stragglers in a crop of Peas are termed, is more often due to this cause than has been suspected, but mostly to the natural tendency of the cultivated Pea to sport and revert back to the original type.

Artificial cross-fertilisation, as practised by Mr. Laxton, was also described as the other plan more recently adopted by raisers for the obtaining of new and improved varieties and the mode of proceeding, as from the flower of the Pea becoming naturally fertilised in an early stage of its formation, and some two or three days before it is fully expanded, the operation, which has frequently been considered a difficult one, although in reality very simple, must precede this. The lecturer divided garden Peas for shelling green into three gastronomic classes as follows:—

1, *Lamb Peas*, consisting of the small early sorts frequently eaten young with lamb in the early season in this country, and answering to the *petits pois* of the French.

2, *Ham or Bacon Peas*.—Those usually consumed with ham or bacon,

and which are generally round-seeded and of a more farinaceous character, and are eaten in a somewhat more mature condition.

3, *Marrowfats or Quality Peas*, consisting chiefly of the larger main crop or later wrinkled sorts, and which are sweet in flavour and of a buttery texture when cooked green.

That in order to meet the requirements for the above purposes and to suit the various soils, positions, climates, and seasons for which the gardener has to provide and the losses by deterioration, he holds that a larger number of sorts of Peas than are generally considered necessary must be maintained. Comparative tables were also given of the best sorts in cultivation twenty-five years ago and of those now in general use.

AWARDS AT THE VEGETABLE CONFERENCE.

Certificates were awarded by the Committees of Selection for the following varieties shown by the exhibitors named.

GREEN VEGETABLES.

Cabbages.—Hâtive d'Etampes, Messrs. Vilmorin, Andrieux & Co.; Offenham, Messrs. J. Harrison & Sons; Hardy Green Colewort, Messrs. J. Veitch & Sons; Red Dutch, Messrs. Dobbie & Co.

Savoys.—Early Elm, Dwarf Green-curved, and Vertus, Messrs. J. Veitch & Sons.

Borcoles.—Extra Dwarf Green-curved and Cottager's Kale, Messrs. J. Veitch & Sons.

Brussels Sprouts.—Deverill's Large Wroxton, Mr. H. Deverill; Paris Market, Messrs. J. Veitch & Sons.

Cauliflowers.—Veitch's Autumn Giant, Mr. J. Lambert; Pearl, Messrs. J. Veitch & Sons.

Globe Artichoke.—Green Globe, Mr. J. Lambert.

Spinach.—Viroflay, Mr. R. Smith; Prickly Seeded, Mr. W. Poupart.

FRUITS AND PULSE.

Vegetable Marrow.—Anglo-Indian, Mr. J. Chadwick; Long White, Mr. W. Palmer.

Pumpkin.—Rouge de Crimée, Royal Horticultural Society.

Cucumber.—Lockie's Perfection, Mr. T. Lockie.

Tomatoes.—Red Chemin and Mikado, Messrs. Vilmorin, Andrieux & Co.; Chiswick Hybrid, Royal Horticultural Society.

Beans.—(Runner) Neal's Ne Plus Ultra, Mr. G. Neal; (Butter) Early Golden Cluster and Filbasket, Messrs. J. Veitch & Sons; (Butter) Sutton's, Mr. R. Gilbert.

Peas.—Duke of Albany, Telephone, Prodigy, and Sutton's Matchless, Mr. J. Lambert.

Capsicums or Chillies (collection).—Messrs. Vilmorin, Andrieux & Co.

Maize.—Extra Early Sweet, Messrs. Vilmorin, Andrieux & Co.

TAP ROOTS.

Parsnip.—Dobbie's Selected Hollow Crown, Messrs. Dobbie & Co.

Beet.—Edinburgh Blood Red, Mr. Hugh Hanan; Dewar's Dwarf Red, Messrs. J. Veitch & Sons; Dobbie's New Purple, Messrs. Dobbie & Co.; (Turnip-rooted) Eclipse, Messrs. J. Veitch & Sons; (Dracæna-leaved), Messrs. Vilmorin, Andrieux & Co.

Carrots.—New Scarlet Improved Short Horn, The Novelty Seed Company; Long Red Surrey, Messrs. J. Veitch & Sons.

TUBERS AND BULBS.

Potatoes.—Reading Russet, Mr. J. Hughes; Reading Giant and King of Russets, Mr. J. Lye; Snowdrop and London Hero, Mr. E. S. Wiles; Suttons' Abundance and Reading Russet, Mr. W. Wildsmith; Adirondack and Early Puritan, Messrs. R. Veitch & Son; Favourite, Mr. E. S. Wiles; Veitch's Improved Ashleaf, Mr. J. Hughes; Wordsley Pride, Epicure, and Renown, Messrs. E. Webb & Sons; Suttons' Seedling, Prime Minister, Suttons' Abundance, and Cole's Favourite, Mr. J. Lambert; Vicar of Laleham and London Hero, Messrs. R. Veitch & Son, Exeter; The Rector and Edgecot Purple, Mr. E. S. Wiles; Reading Giant, Suttons' Abundance, and Hughes' Pink Perfection, Mr. J. Hughes; Suttons' Seedling, Messrs. G. Bunyard & Co.

For any new named seedling variety not in commerce, six tubers to be supplied for cooking, first-class certificates were awarded as follows:—

Victory (Mr. J. Lye).

Duchess of Fife (Mr. J. Hughes).

Edgecot Early (Mr. E. S. Wiles).

Talisman (C. Ross).

AWARDS OF MERIT.

Duke of Fife (Mr. J. Hughes).

Seedling (Mr. R. Clive).

Onions.—Giant, late White Flat Tripoli, for type, Messrs. Vilmorin, Andrieux & Co.; Queen, for type, Messrs. J. Veitch & Sons; Giant Madeira, for type, and large Blood-red Flat Italian, for type, Messrs. Vilmorin, Andrieux & Co.; Giant Zittau, for type, Messrs. R. Veitch & Son, Exeter; Brown Spanish, Messrs. Oakshott & Millard; Main Crop, Mr. Nicholas; Deverill's Improved Wroxton, for type, Mr. W. Pope; Brown Globe, Messrs. J. Veitch & Sons; Bedfordshire Champion, Mr. G. Wythes; James' Keeping, Mr. Muir; Flat, Yellow, or Brown Anglo-Spanish, for type, Mr. H. Deverill; Anglo-Spanish and Rousham Park, Mr. W. Pope; Reading, Mr. J. Hughes; Anglo-Spanish, Mr. Wingrove; Rousham Park, Mr. C. J. Waite, Mr. Bowerman, and Mr. Deverill; Ailsa Craig, for type, James' Long Keeping, Pinesfield, Advancer, and Cocoa Nut, Mr. Deverill; James' Long Keeping, for shape, Royal Horticultural Society; Ailsa Craig, for shape, Mr. W. Pope, Mr. W. G. Gilbert, Mr. J. Hughes, and Mr. R. Kneller; Black Douglas, for type, Mr. H.

Deverill; Black Douglas, for type, Mr. Murray; Blood Red, for type, Messrs. Dobbie & Co.; Southport Red Globe, for type, Messrs. J. Veitch and Sons; Southport Red Globe, for type, Royal Horticultural Society.

Leeks.—Lyons, for type, Messrs. Stuart & Mein; Lyons, for type, Messrs. Dobbie & Co.; Lyons, for type, Mr. J. Lambert; Musselburgh, for type, Mr. C. J. Waite; Musselburgh, for type, Mr. J. Lambert; Musselburgh, for type, Messrs. R. Veitch & Son.

Shallots.—Large red, for type, Messrs. Stuart & Mein.

Garlic.—Mr. R. Smith.

Turnips.—Early Milan (Red-top), Messrs. J. Veitch & Sons; Model White Stone, for type, Messrs. Dobbie & Co.; White Stone, Messrs. J. Veitch & Sons; White Stone, Mr. J. Lambert; Early Marvel, for type, Messrs. Harrison & Sons; Green-top Stone, Mr. R. Moper; Round Red Globe, for type, Messrs. J. Veitch & Sons; Round Red Globe, Messrs. R. Veitch & Son; Golden Ball, for type, Messrs. Dobbie & Co. and Mr. J. L. Ensor.

Kohl Rabi.—Early Vienna, green for type, Messrs. J. Veitch and Sons; Early Vienna, green, Messrs. J. Carter & Co.; Early Vienna, purple, Mr. C. Doman; Early Vienna, purple, for type, Messrs. J. Veitch & Sons.

SALADING.

Celeriac.—Large Smooth Prague, Messrs. Vilmorin, Andrieux & Co.

Radish.—Long Scarlet, Messrs. Vilmorin, Andrieux & Co.; Early Scarlet Forcing, Messrs. Vilmorin, Andrieux & Co.; Early White Forcing, Messrs. Vilmorin, Andrieux & Co.

Celery.—Wright's Giant, Messrs. Oakshott & Millard; Dobbie's Invincible, Messrs. Dobbie & Co.; Sandringham White, Messrs. J. Veitch and Sons; Sutton's White Gem, Mr. J. Lye; Standard Bearer, Mr. F. Taylor; Covent Garden Red, Mr. W. Poupert.

Endive.—Ruffec, from Messrs. Vilmorin, Andrieux and Co.; (Green Curled), Messrs. J. Veitch & Sons; (Moss Curled), Chicorée Parisienne d'Été, Messrs. Vilmorin, Andrieux & Co.

Lettuces.—(Cabbage), Lorthois, Messrs. J. Veitch & Sons; (Cabbage), Blonde Berlin, Messrs. J. Veitch & Sons.

EVENTS OF THE WEEK.—The Royal Horticultural Society's Fruit and Floral Committees will meet in the Drill Hall, James Street, Westminster, at 11 A.M., on Tuesday, October 8th. The National Chrysanthemum Society's Floral Committee will have a meeting at the Royal Aquarium, Westminster on Wednesday, October 9th, at 2 P.M. The Crystal Palace Hardy Fruit Show will take place on October 10th, 11th, and 12th, the British Fruit Growers' Association holding a meeting in conjunction with this Exhibition on Thursday, October 10th, at 3 P.M.

— THE twenty-fourth monthly reading (second of the present season) in connection with the PRESTON AND FULWOOD HORTICULTURAL SOCIETY, will be given in the large room of the Castle Hotel, Market Place, Preston, on Saturday evening, October 5th, when Mr. Alfred Waters, of the Gardens, Farington House, will read his paper on "Brief Notes on Peach Culture. Failure v. Success." The chair to be taken by the President at 7.30 P.M.

— THE WEATHER here has been very stormy of late, with heavy rains and high winds. On Friday last, the 20th, we had thunder and hail. It completely riddled our pot Strawberries, and broke a number of our Chrysanthemums about 2 inches below the bud, leaving only one and two buds on some of them. The same has happened at other places around here; but we have had very little frost, not more than 2°.—GEO. HILTON, *Bolton-le-Moors*.

— THE CHISWICK GARDENERS' ASSOCIATION. — On October 11th, Mr. Shirley Hibberd will DELIVER an ADDRESS on Green Leaves.

— ANTHRACITE COAL.—The value of this form of fuel has been abundantly proved by many practical horticulturists, and some of the advantages claimed for the HENDREORGAN ANTHRACITE are as follows:—A ton will do the work of three times its bulk of coke, consequently in addition to the saving in cost, there is the saving of labour in cartage and handling, besides the decreased space required for storage; it is smokeless; it requires much less attention, fires being good for at least twelve hours after being made up; and it gives a steadier and greater heat by 5 to 10° than is obtained from coke. It is supplied from 23, Lime Street, London, or the Swansea Valley Collieries, South Wales.

— DEATH OF THE VEN. ARCHDEACON LEA.—With much regret we learn that Archdeacon Lea died on Tuesday, September 24th last, at his residence near Droitwich. The deceased gentleman was the author of several practical and useful articles on small farms which appeared in this Journal, and were subsequently published in book form. Archdeacon Lea was educated at Brasenose College, and gained a second class in Literæ Humaniores. He took his B.A. degree in 1842, and the M.A. degree in 1859. In 1843 he was ordained deacon by Bishop Peps, the then Bishop of Worcester, and priest in the following year. The first curacy to which he was appointed was at Rowington, Yorkshire, and in 1844 he was appointed to the curacy of Tardebigge, in this county. In the following year he was removed to St. Peter's, Droitwich, under the Rev. J. R. Ingram, the then vicar, who resigned in 1849. Mr. Lea was next appointed by Earl Somers, the then patron, to the vacant living, which he held till 1887, when he resigned. He was made an Honorary Canon of Worcester in 1858, and was appointed Archdeacon of Worcester in 1881, succeeding the late Archdeacon Hone. He took a deep interest in public affairs, and his much-regretted decease will cause a vacancy in many public bodies. One of these is the County Council, Archdeacon Lea having been elected an Alderman; he was also a county Magistrate, and a member of the Droitwich Board of Guardians, the meetings of which he attended regularly. He was seventy years of age, and his tall erect figure will be greatly missed in the Archdeaconry in which it was so well known. He took great interest in fruit and Rose culture, and won many prizes with products of the rectory gardens at Droitwich. He was also an admirer of game poultry, an aviary of which he kept at his residence. The funeral took place at St. Peter's, Droitwich, last Saturday at two o'clock.

— THE BRITISH FRUIT GROWERS' ASSOCIATION (President, Lord Brooke, M.P.) intend holding a meeting and Conference at the Crystal Palace, Sydenham, on the first day of the Hardy Fruit Show, Thursday, October 10th, at 3 P.M. Important papers on fruit culture will be read by Mr. T. Francis Rivers and other eminent authorities. The Hon. Secretaries are Mr. Lewis Castle, Merton, Surrey, and Mr. William Earley, Ilford, Essex.

— OUR attention has been called to useful material—namely, ALLPORT'S PATENT WIRE-WOVE WATERPROOF ROOFING AND PANEL BOARDS, which consist of waterproofed paper boards or sheets made upon a foundation of fine japanned or tinned steel-wire gauze. For the sides of cheap houses, frames, &c., or for roofing sheds and similar buildings, it will, no doubt, be found useful, as it is admirably calculated to endure exposure to weather influences. Our samples were received from the Patent Wire-Wove Waterproof Roofing Company, Limited, 108, Queen Victoria Street, London, E.C.

— DESTROYING RATS AND MICE.—In answer to "L. K.," I quote a method which I have taken from an old book for getting rid of rats or mice. The gardeners in the vicinity of Paris use a simple trap for these animals, which consists of an earthen vessel or jar, rather narrow at the mouth, but much wider towards the middle. These are sunk in the ground, sometimes partly filled with water, and at other times empty, the mouth being placed level with the surface of the earth, and slightly covered with leaves, twigs, or straws, forming a trap into which many of them fall.—A. G. FRAMPTON.

— THE ECCLESALL (SHEFFIELD) FLORAL AND HORTICULTURAL SOCIETY.—The annual dinner of this Society was held on Wednesday, September 25th, at the Prince of Wales Hotel, Ecclesall. There was a good attendance of members. Letters were read regretting inability to be present from the President (Mr. J. B. Mitchell Withers), Mr. Charles Belk, Mr. David Davy, and Mr. C. E. Vickers. The Rev. George Sandford, vicar of Ecclesall, presided at the dinner. The Society was reported to be in a very prosperous condition, there being an increase of 164 entries. The balance-sheet showed a balance of £18, which was slightly less than last year, owing to the very unfavourable weather on the day of the Show. After the toasts had been gone through, various songs and recitations were given by Messrs. Frost, Willerton, Latham, Lomas, and others.

— GILBERT'S SURPASSE TOMATO.—I see by last week's issue of the Journal that "S. T. W." finds this an excellent Tomato for out of doors, but it has not done well with him under glass. Here we have it under glass with twelve varieties, and we like it as well as any of them. The fruit is of medium size and suitable for market. Laing's Pedigree much resembles it; in fact, I can see little difference between them.

Both are good and well worth growing. I have grown *Sensation* two years under glass, but it sets badly, and does not grow so large as I expected. *Vick's Criterion* has done as well as any with me. It is a handsome fruit, and sets well. Perfection is of great size, sets well, and is of a good flavour. *Queen*, a small Plum-shaped variety, fruits immensely, and is the best flavoured Tomato I know. It is a splendid dessert fruit.—G. HILTON.

— *COLEUS GIL BLAS*.—During recent years several valuable additions have been made to *Coleuses* till we have now varieties which are as remarkable for the elegant form of their leaves as are others for their diversified markings and brilliant colours. *Gil Blas* is one of the best among new varieties, either for growing into specimen plants or for supplying suitable material for decorative purposes. It is a strong grower, and if given plenty of room develops naturally into shapely plants. The leaves are large, and the groundwork of a pale yellow colour, spotted and suffused with crimson magenta when growing close to the glass in full sunshine. This variety is remarkably handsome and showy. Well-grown plants placed singly in water, and used for house decoration, cannot fail to find favour wherever plants noted for the rich markings of their foliage are appreciated.—H. D.

— *SALVIA PRATENSIS*.—This native plant deserves a note of recommendation for the back row of the herbaceous border. If fairly treated its long spikes of blue flowers, often numbering two to three hundred, continue to rise for two months in succession, and form an agreeable contrast to the almost universal *Compositæ* now in bloom. Like other strong growing subjects it should be divided at the roots every few years, watered in dry weather, and the stems which grow 5 to 6 feet high tied up in good time. It is one of the best honey plants, as the bees swarm upon it during bright weather. It is equally attractive to moths, by visiting it at night with the lantern good captures may easily be made. There are said to be both red and white varieties; these I have not seen, and should be glad to obtain.—GEO. WALL, *Breakspears*.

— *MANDEVILLA SUAVEOLENS*.—On page 260 of last week's issue attention is called to this grand old climber by Mr. G. Abbey, and he asks who has tried it in a cool house or against a wall. At Battle Abbey, Sussex, I have seen it growing outside and flowering most profusely. I do not know if it still remains. Its greatest enemies when grown indoors are thrips. In the old nurseries of Messrs. Rollisson's at Tooting when I was a boy it occupied a large space in their conservatory where it flowered magnificently, and beside a pillar adjoining the above was the old neglected *Hovea Celsi*, now seldom seen, which used to flower freely, its bright blue flowers being very attractive. I have seen *Solanum jasminoides* growing outside trained against a house in Southsea, and flowering grandly. Although there are instances of such plants growing outside it does not say they are hardy, but it shows what can be done with many of our so-called greenhouse climbers, &c., in favourable situations.—ALFRED OUTRAM.

— *THE WALLFLOWER*.—The Wallflower in its cultivated state is perfectly familiar to all, but it may not have been the happiness of all to see it in its native habitat, the crumbling walls of some old ruin. While most plants delight in a good body of soil, others seem to thrive under the most adverse conditions, and amidst the cracks in the masonry of some old abbey, where we should expect the lack of earth, the insufficiency of moisture, the scorching sun, and the fierce rush of the breeze to render existence impossible, we often find a perfect garden. We have in such positions seen the Wallflower, the Bugloss, the Snapdragon, Harebells, the Stonecrop, and even such plants as the Elder and the Dog Rose, growing in wild profusion. To this short list many other flowers might be added, and the stone fences that are so common in some parts of the country yield equally "happy hunting grounds" for the botanist and lover of plants. The common name of the plant, Wallflower, is, of course, bestowed upon it from its being so essentially a lover of old walls, but we sometimes find it referred to as the Gilflower, or Gillofer, a corruption of the French *Giroflier* and Italian *garofano*. We need scarcely remind any who read these remarks that the etymology of our language was in mediæval times in a very chaotic state, and we find the plant appearing in various old authors as the *Gilofre*, the *Gyllofer*, *Jereflouris*, and *Gariflus*, all more or less corrupt renderings of the Latin *Caryophyllum*, a name bestowed on it from its Clove-like odour. The name was, however, originally bestowed on the true Clove, a species of *Pink*; and while some of our earlier writers refer to this latter plant as the *Gillofer*, later authors have transferred the name to the Wallflower.—(*Assell's Familiar Wild Flowers*.)

— *CARNATION VALENCIA* is one of the most useful of the whole family of perpetual flowering Carnations. In habit of growth its characteristics are great vigour combined with sturdiness. The flowers are large, full, and deep crimson. Among the many varieties we have grown at various times, *Valencia* easily bears the palm for producing the greatest quantity of flowers from a given number of plants. Unfortunately some of the most beautiful varieties of the family under notice flower but little till the early spring months, although the period during which Carnations are the most appreciated is from the present time till Christmas, and all who require a good supply of these deliciously scented favourites should make a point of striking plenty of cuttings during next February and March. Those who possess plants set with flower buds should now place them near the glass in a light structure, give abundance of air on all favourable occasions, and keep a gentle heat in the pipes when the weather is cold and foggy. To secure flowers of good size and colour, diluted liquid manure should be given two or three times weekly, with an occasional supply of soot water.—H. DUNKIN.

— *EALING DISTRICT GARDENERS' MUTUAL IMPROVEMENT SOCIETY*.—The annual general meeting of members was held last Monday evening, when a very satisfactory report and balance sheet was presented. On Wednesday evening next, the 9th inst., the opening of the autumn session will be in the form of an address to the members and their friends by Shirley Hibberd, Esq., to be given in the Victoria Hall, Ealing, at eight o'clock. Some interesting exhibits will also be staged, and it is the intention of the Society to encourage the production of these at the weekly meetings by awarding marks according to their quality, and at the end of each session the holders of the greatest numbers of marks will have gardening books presented to them as prizes. Mr. Hibberd's address will be followed by others from Dr. Masters, the Rev. Percy Myles, Messrs. R. Dean, J. Hudson, A. Wright, A. Dean, Geo. Gordon, and J. Fraser. On Wednesday, October 30th, a concert and entertainment in aid of the Gardeners' Orphan Fund will also take place in the Victoria Hall, under the patronage of several of the leading inhabitants of Ealing, and a great success is confidently expected. There will be no meeting of the Society on November 6th, as that is the date of the annual Chrysanthemum Exhibition by the Ealing, Acton, and Hanwell Horticultural Society.

— IN Consul-General Playfair's report to the Foreign Office on the agriculture of Algeria, it is said *VITICULTURE* in that country is beset with many dangers. In spring, hailstorms frequently destroy the young shoots; the flowers are often ruined by fogs; and the ripe fruit by the sirocco. The most serious enemy is, of course, the *Phylloxera*, but the officials have been fairly successful in dealing with this pest. Another is the *Altise*, a small beetle that causes great destruction, particularly when in its larval condition. The mode of killing the *Altise* commonly adopted is to place bundles of grass and Vine cuttings around the vineyard when winter is approaching; in these the insects conceal themselves in large compact masses, and the whole is then set on fire. Other diseases are the *Oidium*, *Anthrachnosis*, *Peronospora*, and *Chlorosis*. It is calculated that the want of intelligent treatment of these diseases causes the owners of the vineyards to lose annually nearly a third of the crop. The Olive seems to grow everywhere in Algeria except in marshy ground, and attains dimensions quite unknown on the northern coast of the Mediterranean. At present, however, from careless cultivation, the plant has not proved as remunerative, nor have its products been as good, as in Europe.—(*Nature*.)

— THE British Consul at Bogota, in his last report to the Foreign Office on the *AGRICULTURAL CONDITION OF COLOMBIA* says that for Tobacco cultivation in that country no manure is used, and the same land is used over and over again for an indefinite number of years. In some districts, where disease has completely exterminated the Tobacco plantations, it has been found that when plants are brought from other districts they are not attacked for a few years, but ultimately they are also destroyed. This, perhaps, might be avoided by constantly importing fresh seed; but the experiment was tried on some of the best Tobacco land in Colombia, with the result that as the seed brought from inferior districts began gradually to improve by transportation to the better soils, it became more liable to disease, while the plants grown from seeds brought from the better districts were attacked at once. Another instance of the ignorance of scientific agriculture in Colombia appears in the case of Cocoa. It is most carelessly cultivated, though it is a crop which requires constant care and labour to weed and clean the ground, and free the trees of the numerous insects, especially the cater-

pillars, which infest them. A most destructive disease has lately attacked the trees in the south of the Tolima, which is one of the very richest districts in Colombia. This disease does not seem to have been investigated, and no remedy has been suggested, but the extent of its

APHELANDRA CRISTATA.

At a recent meeting of the Royal Horticultural Society a cultural commendation was awarded for an uncommonly fine example of the

FIG. 37.—APHELANDRA CRISTATA.

ravages will be understood from the fact that one of the plantations attacked produced only 175 lbs. instead of 18,000 lbs. of Cocoa, an astonishing and deplorable decrease.

above named handsome old plant, from the Pendell Court Gardens. The flower heads are much larger and of a brighter colour—a rich shade of red—than any other cultivated Apelandra, and when the plant has

attained good size it is especially attractive. Mr. F. Ross favours us with the following particulars :—

"The specimen from which your figure is taken was from a standard plant some 6 or more feet high, having about 3 feet of stem, with a dense bushy head about 4 feet through, every shoot of which flowered similar to the one figured. Although planted out in this instance, yet it makes a capital pot plant; indeed, in years gone by it was frequently used for exhibition specimens. Its culture is easy, and similar, whether grown in a pot or planted out. After flowering we cut the plant hard back, which induces the formation of several leads, selecting as many of the strongest as will be needed to give the plants a well-furnished appearance; afterwards repot, and otherwise encourage growth, keeping the plant in a light position in a moderately warm and moist stove. A good rich and strong loamy compost best meets its requirements. We keep it free from insects, and as sure as September comes round it yields an abundant crop of its brilliant flowers. Some growers recommend enforced rest after flowering, but I have never seen any advantage from this treatment. It is easily increased by cuttings in the usual way."

TREATMENT OF SOILS AND MANURES.

IN reply to Mr. Tonks' remarks on page 239, if he thinks I am offended he very much mistakes my feelings, and I will not follow his example by seeming to be exasperated.

Mr. Tonks is not satisfied with what I have written, but adds something I have not stated. I do not deny authorities so far as they are used for information and enlightenment, but where are we to stop when scarcely two authorities agree in themselves on many points? Would Mr. Tonks advise us to stop where our tutors left us? I regard instructions as being given for us to develop, and so to improve ourselves. How many excellent gardeners have instructed pupils who in time have found reason to adopt different methods, and thereby brought about better results? Are they ignorant still?

I am sorry Mr. Tonks spent the greater part of his time in ignorance, as fifty years out of sixty is a long time to live in such a state. My age is only half that of Mr. Tonks, and I feel flattered to learn that my mind was capable of perceiving what is right in one-third of the time that it took him to accomplish.

Carbonic acid is carbonic acid, and not carbonic dioxide, and I must repeat that the formula is H_2CO_3 , and the carbonic acid of the air that Mr. Tonks speaks of is not carbonic acid, but carbonic dioxide, CO_2 . I will quote Johnston and Cameron for his information, page 36—"The compound commonly called carbonic acid is carbonic dioxide CO_2 ; real carbonic acid would have the composition given above, which is H_2CO_3 ." Again, on page 37, "Acids are bodies containing hydrogen." As CO_2 has no hydrogen I think Mr. Tonks must confess that he is wrong. In what form carbonic acid exists has nothing to do with the question. The quotation from Watts in the "Dictionary of Chemistry" substantiates my argument that CO_2 is an anhydride.

I am not such an ignoramus as to suppose that carbonic dioxide of the air occupies the whole space, the quantity is very small. Carbonic dioxide is taken in, and at other times given off, by the plants. If a field or piece of land is dressed with fresh lime, and this is left exposed to the action of the air, it absorbs carbon dioxide and forms carbonates; also carbonic dioxide is really taken up and carried down by the rain, and mixes with other ingredients, forming compounds. These compounds are taken in, the calcium, soda, &c., used by the plant, yet the carbon of which half of the dried plant is composed is thrown off or down, and not used. I have stated that CO_2 is absorbed by lime; this is only a plain way of putting it. The real fact of the combination is that hydrogen being present the compound of H_2CO_3 takes place first, and then combines with the lime and forms carbonates. I think it only right that I should make my contentions as plain as possible, whereas if CO_2 is passed through lime there would be no chemical reaction, but only an apparent electrical shock, but in the case of a chemical reaction carbonic acid is taken in water thrown off, and carbonate of calcium and caustic hydrate is the composition left, which most gardeners and farmers call lime. I know, and knew before, that animals cannot live in carbonic dioxide, also that the test given I used in my school days. I was aware that carbonic dioxide was found high and low, even as high as Mont Blanc. This I attribute to the different currents of air. If the gas was lighter than the air it would all ascend.

The forms I spoke of as the various salts or the oxides of metal elements—viz., soda, potash, &c., in combination with carbon, is the carbon divided from or decomposed before being taken in by the plants, or is the compound taken in by the plant decomposed, and the potash and soda used and the carbon thrown off. I have

sufficiently disposed of Mr. Tonks' remarks about phosphorus in my last article written before his reply was printed. The uncertain manure has nothing to do with me. If prepared as I stated there will be no uncertainty, but, like artificial manure, if left exposed to all atmospheric influences both would be useless. Most people know by the sensible reduction of quantity it is harmful to leave artificial manure unprotected. Farm manure is different, it loses its vegetable-producing qualities, but does not diminish in bulk perceptibly. When Mr. Tonks speaks of the advantage of 1 cwt. of artificial manure over farm manure, he means a manure properly taken care of and one that is neglected. I am writing about the neglected as being carefully looked after and protected. Farmyard manure in the fresh state has 28.24 per cent. of organic matter, three months exposed 16.53 per cent. What would be the result with longer exposure? My experience is that manure is more abundant in the country than near London, and the meaning of Latin adages can be found in dictionaries.

In reply to "W. S.," on page 264, I am sorry he should have been put to so much trouble, owing to a slight mistake. The sentence on page 173 should have read, "The larger part of soil being inorganic proves that the mineral elements are far in excess of that required by plants. Is it possible to exhaust the soil of mineral constituents by heavy cropping without returning any of those minerals to the soil?" The next sentence confirms this. They can be reduced by bad cultivation, but not exhausted.

Respecting my "assumed scientific manner," I will ask "W. S." whether it is presumption to have passed through all the stages of agricultural chemistry under qualified men, and to bring my "assumed" knowledge of the subject to bear upon the practical cultivation of vegetables, &c., and thereby produce on ground that was practically sterile or barren such crops as others had failed to procure, and after having been told I should fail, and this with only the resources at hand? Does the presumption come in when I try to put others in the same way of getting the best results with what they have at command? Will "W. S." state where the "unscientific" treatment comes in, and give the readers of this Journal the benefit of his knowledge in garden chemistry? I must thank "W. S." for supporting me in my endeavour to make the best use of all manures at hand.—G. A. BISHOP.

CHRYSANTHEMUMS IN THE SOUTH.

THE time is now fast approaching when Chrysanthemums become more interesting, and as many persons may be glad to know something about the plants in the south I have jotted down a few notes hurriedly made during a short tour amongst old friends quite lately, but not with "the object of viewing the nakedness of the land," as was attributed to me some time since by a correspondent. That the season in the south of England will be an early one no one will dispute, as the buds, crown and otherwise, came at early dates, in some instances too much so to please experienced cultivators, but no doubt they have taken the precaution of not putting all their eggs in one basket, as experience teaches growers that it is more advantageous to grow extra plants of well known and tried varieties than it is to grow fanciful varieties of which they know little. Cultivators have the opportunity of selecting early and late buds of the same sort, so as to extend the season of any particular variety. From what I saw I should think the coming season is likely to be a good one amongst Chrysanthemums, especially with plants grown for the production of large blooms for exhibition.

WARREN HOUSE GARDENS.

My first call was at Warren House Gardens, the seat of Lady Wolverton, where visitors are certain of a kindly welcome by Mr. Woodgate, the popular Hon. Secretary of the Kingston Chrysanthemum Society, and an enthusiastic cultivator. He not only grows to win prizes, but he does not forget the home display, as he has many early varieties to prolong the season; neither does he confine the number of blooms on the plants in all cases to the orthodox three, but for the sake of a few extra to cut from he allows the plants to carry more branches. The plants are grown during the summer in the kitchen garden, having an open position on the sides of the paths, which are well sheltered from south-westerly winds. Earwigs have been in great abundance this season, and taking the earwigs from the traps each morning they are put into bottles with stoppered corks for convenience. The "take" that morning was quite 500. Mr. Woodgate, for curiosity and to prove the fallacy of those who say that earwigs are not injurious to the plants, allowed them to have a "roving commission" over one plant—Duchess

of Albany, the leaves of which were riddled, and to make sure that earwigs were responsible for the depredation he had taken steps to carefully examine the plant in question at various times during the night. The other plants looked well, being stout, yet not gross, but hard and well matured, the leaves of good size, thick, and leathery, and of a good colour, not a yellow or pale coloured plant to be seen, which was a new experience to me. The buds also in most cases had shown at good times to develop fine blooms. The plants were not tall on the whole except, of course, a few of the Japanese that must "go up" to produce satisfactory blooms. Violet Tomlin, Miss M. A. Haggas, both promised as well as their parents Princess of Wales and Mrs. Heales, having good foliage, stout flower stems, and well formed buds, almost certain indications of blooms to follow. These had reached a height of 7 feet. Queens average 6 feet 6 inches, and were amply clothed with good leaves, neither too large nor too small. The buds in this section were coming well to time to perfect shapely blooms. Avalanche was growing well, the flower stems and buds reminding us of miniature drumsticks. The Wolseleys, Alfreds, Tecks, and Heros, as they are familiarly called, looked well, the latter quite dwarf and carrying large leaves. The former two were dwarf compared to their growth sometimes. Early varieties, such as W. Holmes, a brightly coloured useful sort; Duke of Berwick, Fernand Feral, Hiver Fleuri, and many others too numerous to mention were giving early promise of useful blooms. A variety always welcome evidently meets with much favour, Elaine, judging by the numbers and appearance of the plants. Mr. Woodgate has good reason to be satisfied with his plants, which number nearly 500.

MORDEN PARK.

Morden Park was our next call, where our old friend Mr. Gibson received us with his usual heartiness. The locality there being low lying is in favour of a season like the one we are now having, encouraging the production of large and good blooms. I should say having much more moisture in the air during dry weather than where the position is higher, drier, and more exposed. The plants were arranged in one block in a sheltered yet sunny position. Mr. Gibson knows the necessity of allowing plenty of space between the rows, both for the welfare of the plants and convenience of attention to their wants, and as the whole stock is arranged close to Mr. Gibson's cottage it would not be a difficult matter to find him any evening, so engrossed is he with their growth. Judging by the appearance of the stock generally, and they will also bear examination individually, opponents of this "old hand" must not "play light" if they mean to win. The plants are strong right from the base, showing they have had early attention as well as during the summer; different from some one sees sometimes, being no thicker at the base than cedar pencils, then at about 3 feet from the ground a spasmodic kind of help has been given them, and they bulge out in thickness, not at all in accordance with their base. None of this is seen in the Morden Park plants; steady progressive growth, producing good leaves, some would say rather pale in colour, but of that healthy tone and feel which men of experience know must result from the water used. The wood is matured, not too much to cause contraction of the sap vessels. The buds are formed mainly about the time required; of course, in a number there must be some too early for the shows, but they are by their present appearances indicators of what are to follow. On the whole Mr. Gibson thinks they are rather taller than usual, but quite as good as he has had them. The Queens promise remarkably well, averaging about 7 feet high, with buds in all stages. Jardin des Plantes, John Salter, Prince Alfred, Nil Desperandum is here always good, this year being no exception. Mabel Ward is always looked for in the stands from Morden, and this year I fancy not in vain. Refulgens will be this year, I fear, very early, which will be annoying, as the promise is so great. Edwin Molyneux, Avalanche, and M. A. Délaux promise by their extra fine foliage to develop good blooms. The finest plants that I have ever seen of one variety are here; I allude to Grandiflorum. Many who happen to read this, and who are conversant with the blooms shown by Mr. Gibson, will say, "Of course they are always good." Such stems and leaves! No wonder they turn out good flowers. Pompons and Anemone Pompons are more largely grown here than hitherto. Taken all in all a busy season, as well as we trust a successful one, will be experienced.

HECKFIELD.

The number of plants here cultivated for large blooms is somewhat reduced owing to diminished requirements, but the number of "bush" grown plants has been increased, of which the single varieties, as well as Anemone Pompon and Pompon sorts, are conspicuous, and capably grown they are, being clothed with foliage down to the pots, and giving promise of a splendid display later on. The large flowered varieties are perhaps not so strongly grown as in the past, yet they present a remarkably healthy appearance, being clothed with stout leaves and furnished with promising buds. Some varieties have grown extremely tall, owing to the early formation of crown buds which were discarded, while the bulk of sorts average 4 feet to 7 feet high. Avalanche here shows its extremely useful habit of growth, carrying stout foliage, thickly set on almost self-supporting stems, and with most promising flower buds.

SWALLOWFIELD PARK,

The seat of Sir George Russell, near Reading, has become somewhat famous in the Chrysanthemum world through the success achieved at the exhibitions during the last season, especially by Mr. Allen, ably

assisted by his two sons, the eldest of whom acts as foreman and grower. The whole of the plants are arranged along the sides of a path in the kitchen garden, and cannot number much less than 600, forming much the longest avenue I have yet seen. That the position and the treatment the plants have received agree with them no one can deny who inspects them, and with such grand houses as are here to flower them in, opponents of Mr. Allen must not reckon too lightly wherever he is met. On the whole the plants are not so tall as in some seasons, but they are strongly grown without being gross, the leaves of good texture and colour, and good results may be expected. All the leading varieties are found, and some which are useful only in point of numbers or strong personal taste. The Queens were most promising, Lord Alcester especially so, Mr. Allen being no doubt desirous of repeating his success of last year with that variety, with which he secured honours at Kingston for premier incurved. Jeanne d'Arc, Lord Wolseley, Barbara, Princess of Wales and its sports, Jardin des Plantes, and numerous others, the mention of which would serve no useful purpose, but which will, I have no doubt, have to be chronicled later on. Here was growing a fine stock of Mrs. Falconer Jameson, which showed by its dwarf habit and robust leaves that in that respect it is a worthy addition to our short list of low growing varieties.—E. MOLYNEUX.

A VISIT TO THE BULB FARMS OF HOLLAND.

[A paper read before the Nottinghamshire Horticultural Society by Mr. Alfred H. Pearson.]

(Continued from page 273.)

As a rule we have to wait about a week after the Hyacinths are fully out to see the early Tulips, and a few days longer for the double and later ones. This year they bloomed very closely together, and we could see them on the same day; so we will run round a typical Hyacinth farm in the morning and a Tulip farm in the afternoon.

We are staying at Haarlem, the centre of the Hyacinth district, and so well known that all Dutch bulb-growers put "Near Haarlem" on their English catalogues, even though their places are situated about as near to Haarlem as Southwell or Edwinstowe are to Nottingham. Leaving our hotel at 8 A.M., we can take a steam tram to our destination, about twelve miles distant. Our host meets us at the village, and we at once start on a tour of inspection. The land is all divided, by low shelter hedges, into squares of about one-third of an acre each. First we come to some land occupied with Potatoes last year, now a nursery for young stock yearling Hyacinths. There are three rows of beds in each division between the hedges, and about 20,000 "babies" in each row of beds; next we come to several pieces that were Scilla sibirica last year, and here are millions of seedlings on the ground, but the last have been taken up; these will be dug in along with the manure for Potatoes. This nursery is famous for Scillas. We can see acres of them; they were out of bloom, but last year they were lovely when I visited them. Walking on, we come to several enclosures which were last year filled with Hyacinths, and which are now planted with Lily of the Valley; then to a number of pieces where the ground seems empty, but is neatly levelled down; there are Gladioli and Ranunculuses here. But what is that man doing with the barrow and scoop? He has a mixture of cowdung and water in the barrow, and is artistically spreading it over the surface of the land, where it makes a thin crust something like the inside of a thrush's nest, and prevents the sand blowing away. Next we cross a wide ditch, and enter some new land that was levelled last year; here we find the beds filled with common Narcisuses and Tulips. We meet an old man who touches his hat and politely gives us "Good day." Our host says, "That is our oldest workman; he is eighty-three, and is always busy; we never tell him what to do, he can always find plenty of work." We inquire about wages, and are told that the men are still on short hours—from 6 A.M. to 7 P.M., so their wages are about 2s. per day; shortly they will work long days, from 5 A.M. to 8 P.M., and then they have 2s. 6d. The old man keeps these hours, and grows some bulbs of his own, and for years has rose at 3 A.M. to work a couple of extra hours in the morning, and often puts in an hour at night.

We must walk on, for the sun is getting hot and time flies. We come back to the old ground and reach a piece devoted to "mothers"—hollowed bulbs and crossed, and again beds of one-year bulbs. You will notice that each sort is in duplicate, some in triplicate, half a bed or a whole bed of each; that is to prove the stock and to see if it is free from disease. Here we come to bed with blanks in the lines; disease has shown itself here, and that bed, although carefully rid of every tainted bulb, will not be propagated from; the next, which is quite healthy, will be used. As we pass out of each section we notice a large stock of reed; this has been used for covering the bulbs in the winter, and the Dutch growers say that we in England, as a rule, do not take half enough care of our bedding bulbs during the winter to ensure a good display in the spring. Most of us know how disastrous a severe winter is to unprotected bulbs in beds, and I remember some few years ago that a number of small circular beds at Chilwell, which were filled with Tulips for trial, presented at the time of blooming a most curious appearance, having perfect blooms all round the outsides, whilst the centres were spoilt. This was owing to their being raised in the centre so that the snow was there, rapidly melted, whilst around the outer circumference it remained and protected the bulbs from frost. Ah! here is the fell disease again, as we see a blank at the end of the bed; no, that is where the rats have been at work; they often play sad havoc

during the winter, when they get under the reeds and snow, and cannot be seen.

We must hasten on, for we want to see the patch of "Emperor" Daffodil with 10,000 bulbs all in bloom. What a sight it is when we reach it; surely anyone would go Daffodil-crazy here! I feel touched a little myself. On the next square are nearly as many "Empress," and our old friend "Horsefieldi" by thousands close by. Those who only see these beautiful plants grown singly can have little idea of the effect produced by these huge masses with their luxuriant foliage. Leaving here, we go down to some fresh land planted with Hyacinths—somehow they look brighter than ever they do with us; that is because we do not plant them thickly enough to get the true effect. Here they plant the beds according to the size of the bulbs, beginning with the largest, which are set about 6 inches apart each way, and graduating them down to the smallest of the same age which stand thicker; not very artistic, you will say, but it gives a grand effect of colour *en masse*. The one and two-year bulbs are seldom planted near the older ones, as the growers don't like "to have all the eggs in one basket," in case of spring frost, &c., added to which a change of land is beneficial, so that most of the best growers have farms at a distance where they grow the young bulbs for one or two years and then finish them on the very best land they have. Now we come to a bed of Hyacinths all one colour; surely they are "Robert Steiger!" Yes, and just for curiosity we will count them. Thirty-nine beds 10 yards by 1 yard of large bulbs, and three beds of small; 700 on the first bed, and more on the others; not less than 50,000 of this one variety, and only one man's stock.

There is much more to be seen, but we are tired of looking, and before we leave we want to run down over the canal there and see the old lake of Haarlem which was drained during this century. The land is much lower on the other side of the canal, being 18 feet below the level of the sea, whereas the general run about here is 8 feet below sea level. Looking down from the canal bridge we seem to be on the edge of a basin of which the canal forms the rim all the way round. This basin, which is the old lake bottom, is perhaps twelve miles across; the land is strong, and is used mostly for corn growing. Crossing about the centre is a large canal, and into this the water is lifted by wind-power pumps from the ditches, from thence into the outer canal, and finally into the river, whence it goes into the sea at low tide, and is pumped out when the tide is too high. A similar system prevails all over this part of the country. Each wind-power pump has a man in charge, to whom is entrusted the drainage of about 100 acres of land, and by his house is a marked gauge showing the level at which the water is to be kept according to the season. Coming back, our friend tells us much respecting this wonderful drainage, of how when they get short of water, in the summer the sluices are opened from the river, and the ditches filled with water from the old Rhine; of how last winter during a stormy night the sea-bank threatened to give way, and the alarm bells rang all night in the town of Leyden, which is 8 feet below sea-level; more about pile-driving, and the new railway station at Amsterdam, which is built on piles 120 feet long. But interesting as all this is, we must say adieu and hurry on, or we shall never reach the Tulips we want to see. True we have seen plenty of Tulips already to-day, but we are going now to the home of the Tulip.

We mount once more into the steam tram, and whilst it takes us to our destination (perhaps, by the way, it does not go there direct, but no matter) we will just make notes on what we have seen. The first thing that strikes an observer, after a careful inspection of a Hyacinth field, is the number of varieties which are second rate and inferior to others growing around them. If the observer has an inquiring mind he will ask as I did on my first visit to Holland, "Why do you grow this and that when others are so much better?" The answer came, "Were they not in your catalogue last year? Just so, and there are numbers of people who year by year order varieties which are long out of date, and superseded by newer ones; the only other reason they are grown is that they are cheap." Having then marked the second-rate names off, we make notes of the good stocks we have seen, as we have done at other places, not forgetting those Queen of the Blues measured yesterday in the fields, with spikes 8 inches long. Time was when the few men who exported bulbs grew each their own speciality, and purchased the specialties of others. There are so many exporters that they are jealous of each other, and each man tries to grow and sell everything. The Hyacinth man grows Tulips, and the Tulip man tries to grow Hyacinths; so if you wish to have really the best of everything you must buy largely, so as to make it worth while to get the best each man has. Some who come to England for orders have little ground of their own. They buy up what they want at the auctions, for thousands of people grow bulbs and sell them by auction who are not in the trade at all, just as Lincolnshire farmers grow Turnip seed. Where do all these little half-starved bulbs go to that we see in every cottage garden, in the railway porter's garden alongside the line and elsewhere? Probably, like the Potatoes, to England. Certain it is that with such a demand for Tulips as there was last season, when all the best growers were sold out almost before the season began (at fancy prices), they would never send their bulbs over for sale by auction, and yet there were plenty to be bought much under wholesale prices. Are all the Dutch growers who sell retail in England connected with the best houses here? Certainly not; a man like our friend we have just left would not accept a retail order; he would not attempt to do both trades. Some who advertise as retail traders are much in the position of merchants. So far as what they grow themselves is concerned they have the advantage of saving an intermediate profit, but they cannot grow all they require, and if they

attempt to do so they simply arrive at a very second-rate all-round produce. For what they want to buy they are very much worse off than the merchant, for the best growers prefer to supply their English customers who come regularly, rather than to trade with Dutch retailers. When you take into consideration the fact that the merchant saves very much by importing in large quantities instead of paying carriage on small retail lots, you can readily see how it is that he can, if he understands his business, compete on favourable terms with his Dutch rival.

I do not think our tram has had anything like time to reach its destination whilst we have been making our notes, but we must anticipate, for time flies. As we look out of the window we see the country has changed during the last few miles (our tram runs about twelve miles an hour including stoppages, so we are getting over the ground). We have left the pleasant flat meadows which seem so full of cattle that one wonders where they go for a change of pasture, and we now find the soil getting stiffer and principally arable; to speak correctly, it is principally under the spade, and really some of it seems as if there were enough men employed upon it to ruin anyone. Look at those seven men digging on that narrow strip for Potatoes, and women planting after them; one would think their wages would purchase the crop, and if you look all around the land seems all over men. These towns we see here, which are only four or five miles apart, are almost wholly agricultural, but then, you see, there are no scattered houses as with us. Everyone lives in villages or small towns, and the men and women walk backwards and forwards to their work. In our own fen country it is much the same, and probably in a country which is at any time liable to be inundated by the bursting of a bank, it is safer to live together than scattered in old houses. Looking out we see here a field of Strawberries and there a field of which you cannot guess the crop! No, it is Roses; they are grown in long lines of cut-down bushes, and the flowers are picked for Paris perfumers.

Now look out of the window behind; the sun is shining his best, and what a glare he shines upon—a crimson sea! Yes, those are Scarlet Van Thols, and as nearly as I can guess there are three acres of them. A little further and our host meets us. Let us leave our overcoats, which have not been of much use to us to-day, and make a start. Of course, as this is the home of the Tulip, our host is very anxious to show us his Hyacinths. We have seen such numbers of Hyacinths that we do not care to see more, but we wander on, and see acres of Hyacinths old and young, and really the stock of one or two sorts is very fine, notably the Giganteas. After seeing the Hyacinths, we cross the road and come to some Narcissus, a very fine lot of Golden Spur, and some good beds of Horsefieldi. Then we come to some Tulips set out in pieces of about half an acre each. What a sight! I never saw such Keizers Kroon; they are immense. As you stand over them they are fully expanded, and the blooms hide the whole ground, not as you see them in some of our parks like plums in a sailor's pudding, but set out 4 inches apart every way. Then we see acres of La Reine, principally grown for the London and Berlin market growers. By the way the Scarlet Van Thols we saw as we were coming were evidently part of a farmer's property. What becomes of them all? Our host tells us that one London market grower uses half a million annually of this one variety, and it is not at all uncommon to have an order for £200 or £300 worth of Tulips from one grower. These market orders are very useful, for they take the rough bulbs that the merchant would refuse. They bloom as well as the others, but are not so clean and pretty for retail work. Of course the market grower has them cheaper, and now I understand what I never did before—viz., how it was possible to bloom bulbs for sale at a profit. The ill-shaped Hyacinth bulbs are mostly sold to Germany for the same purpose. The Germans are very fond of forced Hyacinths, and they do very well for the immense cart-wheel bouquets they make up. In our English markets there is little demand for them.

We walk on. Another acre, this time brilliant with yellow Chrysolora, then a piece of that lovely silky carmine Proserpine, which one can distinguish as far as one can see it; then pieces of Van der Neer, Cardinal's Hat, Yellow Prince, Duchesse de Parma, Joost von Vondel, various Van Thols, Pottelbakkers, and others too numerous to mention. The doubles are hardly out, but if I should see another year I intend to come a week later, and have a full Tulip treat. Meanwhile, in passing we must stop at this bed with variegated foliage. They are really beautiful, quite as handsome as variegated Yuccas. What a talk they would make in Nottingham arboretum just as they are here. This variety is rather expensive yet, but the variegated Purple Crown is an excellent variety and cheap. Some of the variegated sorts are not much good. Strangely enough some do not produce flowers when the leaves are variegated, and as soon as they bloom the foliage assumes its normal hue.

Leaving the Tulips, we come to a fence of wire netting and a shelter hedge made of reed. Behind the latter we find beds of *Lilium lancifolium album* and *roscum*. The wire is to keep the hares from the Crocus, of which we find an acre or so of Mont Blanc (the finest of whites), and others in smaller plots. A short walk takes us to another nursery, where we find a number of *Polyanthos Narcissus* just coming into bloom. What a grand lot of Bazelman major! How strong and what blooms! This variety, which is undoubtedly the finest grown, is unfortunately bad to propagate, and the stocks are small and very scarce. Does it strike you that the foliage is scorched and sickly? That is the effects of the frost, and one but rarely sees the beds in Holland when the leaves have not been caught by spring frost. The blooms are often lovely, but they seem to be too happy compared with their blighted leaves. I feel sure from this that one need not try to grow the

Polyanthus Narciss out of doors in England, its place is in the conservatory. You and I find the utmost difficulty in distinguishing more than six or seven varieties of Polyanthus Narcissus. Yes, and so I believe do the growers. They tell you that these two are just alike except the hulbs, which vary a little. The fact is two are catalogued, and people ask for them. The grower has years ago chosen the better of the two, and sells it for both. On our way back we pass acres of small Tulips, and as we approach the large canal we see a huge field covered with that tender russet brown which denotes the young growth of *Spiræa japonica*, or, as the Dutch call them, Hoteia. There are scores of acres grown on the heavier and damper land which will not grow hulbs. Our host could show us much more if we would stay, but we have been walking three hours with him, and now the day is declining, and we have a long ride before we get back to our dinner. Of course we must smoke a cigar with him, and drink a little glass, for the Dutchman is the soul of hospitality, and would be quite hurt if you did not take something with him.

I always find myself quite at home in the Netherlands—the people, the manners, the cleanliness all seem to remind us of home; everything except the language, and that is fairly easy for a Scotchman. Everything did I say? No, I must make an exception. One rarely sees a beggar, and abject poverty is almost unknown. True, there are not so many millionaires, but the towns are smaller, and people do not get lost as they do in our fearful metropolis, and either starve, or what is almost worse, work for such wages as starve themselves, whilst they take employment from others. The working man in the Netherlands keeps long hours—*i.e.*, in the summer. I suppose he cannot do much in the winter, but he seems contented. His sabots or wooden shoes cost him 6d. a pair, perhaps 10d. if he is stylish. They keep his feet dry and warm in winter, as I can testify, having worn them myself, and in the summer he can keep his feet cool, or fairly cool, walking in the hot sand, whereas in boots one feels the heat very much.

I have been particularly struck on the bulb farms with the appearance of politeness and goodwill displayed between employers and employed, and I know that a good feeling exists, for when I ask a large grower, "What do you do with your men in the winter?" he replies, "Oh, there is always something; they must live in the winter as well as the summer." In making this remark I would not draw any contrast between Dutchmen and our own people, for if an employer cannot get on with English workmen it is generally his own fault. I have been moralising some time, but have not been keeping our host waiting, for we bade him good-bye some time ago, and are rolling along in the steam tram towards our well-earned meal and repose.

ROSES ON THEIR OWN ROOTS.

WHILE thoroughly endorsing all that "Utilitarian" (page 82) says in favour of raising Roses on their own roots, it might be well to give another system of attaining the same end. It gives an additional chance to those who have not availed themselves of the way recommended by him, and who might still wish to put in a few cuttings this autumn, for which there is still ample time, for November is as good a time as any for this operation. As a frame is not required the system has the advantage of great simplicity, and when properly done will ensure a strike of about 80 per cent. at least. Select a shady border, under a north wall for instance, so long as it is free from draught. If the soil is of a tenacious nature it is well to fork-in a quantity of leaf soil and sand, but if moderately free or sandy this will not be necessary. When the ground is ready set the line. Take out a narrow space with the spade about 7 inches deep, cast a little sand along the bottom, and insert the cuttings about 6 inches apart, and a foot between the lines. Tread the soil firmly when filling up the lines, and leave the ground level. When finished spread about an inch of sand over the surface, and by the following November there will be quite a forest of Roses, fit to be removed to their permanent quarters.

As to the cuttings I always make them from 12 to 15 inches in length and of medium wood, if with a heel so much the better. It will therefore be seen that they are about half in and half out of the ground. As Mr. David Thomson said in a January number of this Journal, they will continue to grow and throw up fresh shoots like Osiers when generations of Briar-worked Roses have passed away. It may surprise many to know that tender Tea and China Roses may be propagated in this way, while such as *Gloire de Dijon*, *Rêve d'Or*, and others similar to these root more freely than the Hybrid Perpetuals.

About the middle of last November I had a mixed lot potted that had been put in exactly twelve months before, and in April they bloomed as well as the older Briar-worked ones, and better in some instances, as the blooms of *Magna Charta* would not have looked out of place on an exhibition table. At the same time I remember when I first began this way of propagating Roses some sixteen years ago I potted a number, and top-dressed them heavily with hen dung in spring. They

grew well and bloomed magnificently, but lacked the Rose's greatest charm—they were totally without scent, while the older established ones treated the same way were all right. It is needless to say I have never resorted to a similar top-dressing until the second year at least.—H. C. W.

A ROSARIAN'S INVENTION.

ON Saturday afternoon last the whole of the officers and Committee of the Preston Fulwood Horticultural Society were entertained at luncheon in a large marquee, erected for the purpose upon the lawn at the residence of Mr. Samuel H. Stott, Linden House, Fulwood, Preston. This gentleman is an expert in Rose culture, and is a frequent visitor at some of the principal exhibitions. He has a large collection of all the most popular varieties, and for many months past has been engaged in his leisure hours by an endeavour to invent a scheme by which insecticides and manures might be distributed for both cleansing and feeding purposes. Mr. Stott's endeavour has proved successful, as was shown at the various trials of insecticides and manures which the members, numbering over forty, were invited to witness.

The distributor is a vessel made of either zinc or iron sheeting, in the shape of an ordinary 4 or 6-inch hot water pipe, with two divisions causing three or more cells. At either end a hosepipe is attached, the latter being fixed to the water supply of the house, or from any other source from which there is a downward course in the direction of the distributor. With the water connected, all that remains to be done is to put the desired insecticide soap or manures into the cells. The water now turned on passes through the instrument. The water in passing through dissolves and carries with it the properties of the soap or otherwise, which are distributed by a man at the hose in the same way as clean water would be put on from any water supply in the ordinary way. The strength is regulated by filling one, two, or more of the cells, according to the requirements.—A. W.

THE ENGLISH ARBORICULTURAL SOCIETY.

A VISIT TO ALNWICK CASTLE.

THE fifth annual excursion of the English Arboricultural Society took place on Wednesday, September 18th, the place chosen being Alnwick Castle, permission having been kindly given by His Grace the Duke of Northumberland. It was a lovely September day, the sun shining brightly, cheerful, and yet not too warm, adding considerably to the pleasure of the visitors. The party met and breakfasted at the Crown Hotel, Newcastle, and left by the 8.20 train for Alnwick, where they arrived at about 10 A.M. They were met by the head forester, Mr. J. D. Coxon, who conducted them to the gardens, when they were met by the gardener, Mr. Geo. Harris. On entering the visitors were much struck with mixed beds, which had a most pleasing and telling effect. The large conservatory or winter garden, which is 120 feet long, 60 feet broad, and 30 feet high, was visited, and well repaid the trouble. All the usual greenhouse plants were doing well, but the great feature was the climbers round the posts which support the large roof. *Lapageria alba* was 25 feet high, flowering most profusely. Mr. Harris never entwines the shoots, which causes them to fall in graceful festoons, and the large clusters of white flowers are seen to much better advantage. *Lueulia gratissima* is showing over 100 heads of flowers, and even the laterals are all showing flowers. *Fuchsia Carolinae* has grown 35 feet in four years, and was profusely draped with flowers from top to bottom, and the charming *Clianthus puniceus* is also in a very flourishing condition, and is likely to flower well in February. There is also the rare *Bignonia Chirire*, which has the remarkable character that in its early stages of growth the leaves are small, but as the growths develop the leaves increase proportionately. There is also *Tacsonia Von Volxemi* and *Solanum jasminoides*. In this conservatory were some plants of *Chrysanthemum G. Vermig*, which was splendid both inside and out. Mr. Harris considers it invaluable.

We next entered the vineries. A range of about 120 feet divided into three compartments. These were planted some fifty years ago at considerable expense, the borders extended, and from 4 to 5 feet deep. This depth of rich soil is considered by our guide far too much; 2 feet 6 inches is ample, and artificial food can be employed better and safer to them under these conditions. These Vine borders are gradually being restored. By noting carefully the northern climate here it is found that all the thick-skinned Grapes are six to seven weeks later than the thin-skinned ones, and it is advocated that all late Grapes be started by the first week in March, and Muscat of Alexandria on no account later. The favourite late Grape is Mrs. Pince, then Trebbiano, Lady Downe's, and Pearson's Golden Queen. The bunches averaged from 2 to 3 lbs. each, were large in berry, and likely to finish off very well. On emerging from this range our attention was drawn to some fine horizontal trained Pears of *Beurré Clairgeau*, a good cropper, and a much esteemed Pear in the ducal kitchen. *Beurré Diel* was good, and Louise Bonne of Jersey had an excellent crop. In the borders worthy of note were Roses flowering from the second growth. The principal varieties were *La France*, *Gloire de Dijon*, and *Souvenir de la Malmaison*, the latter is often seen good in the north very late. We again entered two fine Muscat of Alexandria houses planted in 1885. These houses are 30 feet long, 18 broad, and 16 feet high at the apex. Fine new hay was spread all over the borders inside to stop the ascending moisture, and removing the hay the borders were seen to be quite damp under-

neath, and yet no moisture seemed visible in the house. These were started the second week in March; they are just now finishing, and are faultless in colour, size of berry, and bunch. The bunches average 3 to 4 lbs. each, are a heavy crop, and regular all over the house. The usual Vine soil was used with Ville's manure, and each year about 2 lbs. to the square yard is allowed as a top-dressing. The growths of the wood were splendid; joints of the shoots were only from 4 to 4½ inches apart.

The pinetum is known to the many readers of the Journal to be very extensive, and was very interesting to the visitors. Notable were *Abies Veitchi*, *Cedrus Deodora*, *Abies nobilis* and *Douglasi*, the latter not so good where it has caught the winds; *Picea monticola* and *Thuja plicata*. A fine plant of *Abies Englemanni glauca* was pointed out, some contending it was *Parryi*; however, they all agreed the latter was the harder. *Abies grandis* was pointed out to be the hardest becoming tree for glens and dales, while it was stated that *Abies Douglasi* would fast take the place of the Silver Fir as a timber tree, it makes as much as 3 to 4 feet in one year. In the kitchen garden were some fine Cauliflowers, Early London planted 15 inches apart, as they are cut in a small state by the thousand. King of the Cauliflowers is also a great favourite, and London Rosette Coleworts were also planted in thousands after Potatoes. Some fine late Pears of Hacon's Incomparable, which comes in December and January, were noted here; it is a great favourite. Marie Louise and Glou Morceau were also spoken of highly.

From the top tier is observed a fine view of the flower garden, terrace, glass houses, &c., which were all fully described by Mr. L. Castle two years ago. This fine flower garden was designed by the present Duke, and contains his coats of arms worked in crescent shape. We may here mention the promenade round the tennis court. This is an agreeable shady resort. It is planted with Lime trees about 9 feet apart and about 14 feet broad, these have been trained over some wirework about 11 feet high: the whole work has been very successful. In another portion of the kitchen garden, and were pointed out some magnificent Onions, spring planted, of Rousham Hero; the size much astonished the visitors. The secret of success was not kept back; it was by raising them in a frame and pricking out early. This is a hint that kitchen gardeners would do well in the cold north to take note of. Mr. Harris pointed out that through another hint in a recent article by Mr. J. Wright on Apples, that he had procured about a dozen trees of Domino Apple, which he was of opinion as a kitchen Apple would prove an undoubted success at Alnwick. It is rather like Ecklinville Apple, except the eye, and a small tree had eleven fine fruits. Peas were doing well planted 15 to 16 feet apart from each other. Veitch's Perfection and Ne Plus Ultra were especial favourites; amongst newer varieties Duke of St. Albans was also a favourite. As our time was short we had to take a reluctant leave of Mr. Harris.

The party next proceeded to the Abbey grounds by way of Forest Gate, under the guidance of Mr. J. D. Coxon. There is much to interest the historian at Alnwick, and we may just state that before entering the park we observed the place where William the Lion was taken prisoner in besieging Alnwick Castle in 1174. The Stocking Drive contains many fine specimens of trees, a *Wellingtonia gigantea* 45 feet high and 13½ inches quarter girth attracted much attention; the *Abies nigra* was 30 feet, and some *Abies nobilis*, 38 feet, were also observed; *Pinus Cembra*, 45 feet high, 10½ inches quarter girth, 4 feet up; *Thuja gigantea*, a fine *Liriodendron Tulipiferum*, and *Ailantus glandulosa*, 41 feet high, commonly called Tree of Heaven; a fine *Abies Douglasi*, 63 feet high, and at 5 feet 9½ quarter tree. This tree was only planted twenty years ago. Crossing the Aln over a graceful suspension bridge a fine view of the castle is obtained. Here are some fine specimen *Abies Douglasi*, and a *Betula alba pendula* attracted general attention, which was about 60 to 70 feet, and 5 feet from the ground 17½ inches quarter girth. On ascending a hill well above the Aln a fine view of the historic abbeys, Alnwick and Hulne, were obtained. The landscape here is a charming combination of woodland dale and valley, watered in tortuous and winding courses by the rippling Aln. Hulne Abbey was a Carmelite monastery, it is said, and owes its name to the hill having a strong resemblance to Mount Carmel. It is supposed to have been built in 1240 by one Ralph Fresborn, and the ground given by William de Vesey. Alnwick Abbey was founded about 1147 for a colony of Premonstratensian canons. The foundations are large, and were lately excavated by the present duke so as to show the lines of the foundations, and these are clearly defined in gravel. There is also a flagstaff pole over 100 feet high, that was, it is said, even higher, and was a Vancouver Pine given to a former member of the ducal family. From there we proceeded to what is called the Far Stocking Park Dene, where there are some fine Larches, one 28½ inches girth at 5 feet from the ground, 100 feet high, containing about 250 cubic feet of wood, was planted about 140 years ago, and for ready money in the market would yield about £16. From there we come to what is termed Brissle Tower. This was built by Hugh, the first duke. It is built in the pseudo-Gothic style in the year 1781. Many fine trees were blown down in 1881. The view is of the most charming description, the Cheviot Hills and many other objects of historic interest can readily be seen on a fine day.

By way of Dingle Drive and Catreugh Wood we proceeded to Hulne Abbey, already mentioned, passing by the Lady's Well, a spring of pure water. A short distance from here is the Trysting Tree, a gnarled and venerable Oak, very hollow and much decayed. It is known to have been a great tree in 1624. A little to the east of the Lady's Well are

several fine specimens of the Silver Fir, some of which reach a height of from 108 to 114 feet. The girth of the tallest is, at 5 feet from the ground, 14 feet 6 inches. A little further east still is an *Abies Douglasi*, over 100 feet high. Several of the Silver Firs contain about 400 feet of wood, and some sold in 1876 contained 576 feet. In the fine old ruins of Hulne Abbey are several Service or White Beam trees, and here again occurred an interesting discussion, Mr. Brown of Hexham contending that they were not synonymous terms, but that the Service Tree was more serrated in the leaf, which opinion was generally supported.

The party drove back to Alnwick, as dinner was to be ready at four o'clock, which was served in good style at the White Swan Hotel, Alnwick. The usual toasts were proposed, and Mr. Wilson, Leazes Park, Newcastle, was presented with the bronze medal of the Society for an essay "For Suitable Trees for Various Soils and Climates." The chair was occupied by Mr. T. Dodds, Eilan's Gates, Hexham, and the vice-chair by Mr. Isaac Batty, of the same place. The following were present:—Mr. J. Davidson, Sec. and Treasurer, Haydon Bridge; Mr. Wm. Fell, Mr. Wm. Milne, and Mr. Brown, all of Messrs. Wm. Fell and Co., Hexham; Mr. John Balden, jun., and Mr. John Balden, sen., Dilston; Mr. Luke, Greenshaw Plain; Mr. J. Scott, Newton Hall; Mr. Ralph Shipley, Plunderheath; Mr. Clark, Blenkinsopp Castle; Mr. Thos. Vasey, land agent, South Shields; Mr. D. Smith, Scremerston; Mr. and Mrs. Graham, Findon Cottage, Durham; Mr. J. Wilson, Leazes Park, Newcastle; Mr. H. T. Crook, Manchester; Mr. J. Robinson, Burnopfield; Mr. Bernard Cowan, South Shields; Rev. W. Johnson, F.R.S., Gateshead; Mr. W. Taylor, of Little & Ballantyne's, Carlisle; Mr. Gallie, forester, Ravensworth Castle; County Councillor Davidson, South Shields; Mr. Geo. Cooper, Superintendent Gateshead Cemetery, Gateshead; and Mr. Jos. D. Coxon, forester to His Grace the Duke of Northumberland. The latter gentleman proved a good and constant guide all day from 11.30, and had it not been for that gentleman's tact the visitors would not have seen so much of the fine woods in the short time they were there. Several new members were proposed, and all parted highly pleased with the day's proceedings. The fine weather they experienced, and the pleasure enjoyed in visiting the Duke of Northumberland's stately domains will be long remembered.—BERNARD COWAN.

HARDY FRUIT GARDEN.

GATHERING APPLES.—This in most cases will not be a laborious undertaking, but if there is a scarcity of fruit there is a greater necessity to take extra care of the fruit. In many gardens the tits and blackbirds have been most destructive among the fruit, and it was a case of gathering early or having none to store. As a rule, however, it is unwise to gather the fruit before it parts freely from the branches, or until the seeds are nearly brown. If these tests are not applied, the Apples being dragged from the trees, the chances are the greater portion will shrivel prematurely. This applies to all varieties, whether early or late, but it is of the greatest importance that the keeping sorts be the most carefully tested prior to gathering.

STORING APPLES.—Whether the fruit will keep well or not, much depends upon the way in which they are stored, the quality or flavour being also quickly impaired under certain conditions. Many of the modern fruit rooms are light and airy, latticed shelves being provided for Apples as well as for Pears, but it does not follow that the fruit of the former will keep any better or even so well under this presumably favourable treatment than it did formerly in more makeshift quarters. The simple methods of storing sometimes adopted by those in charge of comparatively small places are sometimes the best. Apples keep admirably in clean sweet boxes or casks, and also in hampers lined with paper, these being stored in dry cool lofts or rooms, and not interfered with till required for use. It is of the greatest importance that only quite sound fruit be stored in this manner, as one decaying fruit in the lower portion of the mass will soon infect the others. Sound Apples will keep surprisingly well in such positions, and also when stored in heaps in a cool dark room, or even in the open and protected with clean straw, or much as Potatoes are clamped. In the case of dessert fruit especially sweet surroundings are of the greatest importance. Apples being of a soft porous nature soon absorb any effluvia to which they are subjected, and for this reason ought not to come into contact with musty hay or straw, nor be confined in an impure atmosphere, such, for instance, as pervades a disused Mushroom house. The shelves or floors should be lined with nothing but clean kitchen paper, as quite fresh straw or hay eventually becomes musty, and imparts an objectionable flavour to the fruit. Boarded floors ought especially to be covered with paper, this effectually excluding cold air draughts, and paper coverings freely used will protect sufficiently in frosty weather. If the fruit is stored in a well heated fruit room, fire heat should be turned on sparingly, or only sufficiently to prevent a very low temperature being reached, or otherwise premature shrivelling will inevitably result.

APPLES THAT KEEP WELL.—Good keeping Apples are of the greatest value, and it ought to be almost unnecessary to point out how unwise it is to use them in a reckless manner or long before they have attained perfection. Only those that will not keep, this including any that are damaged in any way, ought to be used now, the rest being kept as much as possible till their proper season has arrived. By way of a guide to the inexperienced it is advisable to mention a few of the most popular late or semi-late Apples, adding their time of maturity or when they are fit for use, beginning with culinary varieties. Stirling Castle and Nonesuch are in season up to the end of October; Emperor Alexander, Golden Noble, Waltham Abbey Seedling from September to December; Cox's Pomona and Cellini during October, and sometimes till the middle of November; Hawthornden frequently keeps good to December; Ecklinville Seedling, Flower of Kent, Hollandbury, Kentish Pippin, and Mère de Ménage are available from October to January; Beauty of Kent, Lady Henniker, Kentish Fillbasket, and Winter Hawthornden are at their best from October to February; Blenheim Pippin, Fearn's Pippin, Tower of Glamis, from November to February; Dumelow's Seedling, Royal Somerset, and Warner's King from November to March, and sometimes even later; London Pippin, Alfriston, Winter Greening, and Norfolk Stone Pippin from November to May; Dredge's Fame, Hanwell Souring, and Winter Pearmain from December to March; and Winter Majetin, Hambledon Deux Ans, and Norfolk Beefing will frequently keep good to June. Dessert Apples are even more scarce than culinary varieties this season. Of these Early Nonpareil and Gravenstein are good from October to December; Cornish Aromatic and Golden Winter Pearmain October to January; Cox's Orange Pippin, Court of Wiek, and Mannington's Pearmain October to March; Downton Pippin, Ross Nonpareil, Margil, and Sam Young, November to February; Claygate Pearmain, Golden Pippin, Braddick's Nonpareil, and Golden Rennet, November to April; Adams' Pearmain, Rosemary Russet, and Melon, December to February; Golden Knob and Ribston Pippin, December to March; Newtown Pippin, Cornish Gilliflower, Court Pendu Plat, Lord Burghley, and Northern Spy, December to May; Cockle's Pippin, Scarlet Nonpareil, and Duke of Devonshire, January to May; and Sturmer Pippin February to June, the months named being inclusive in every instance.

GATHERING AND STORING PEARS.—Much that has been advanced regarding the time to gather Apples also applies to Pears. It is a very great mistake to drag these from the trees, this being especially the case with Glou Morceau, Beurré Rance, Easter Beurré, Huyshe's Prince of Wales, Chaumontel, Beurré Bachelier, Beurré d'Aremburg, Josephine de Malines, Bergamotte Esperen, Nec Plus Meuris, Olivier de Serres, and Madame Millet, all of which if not gathered too soon or not before they part freely from the trees when carefully raised out of their natural position, will keep late, and as a rule ripen satisfactorily. Gathered too soon they shrivel badly, and never attain perfection. In any case it is useless to attempt keeping fruit recently damaged by birds, and these may well therefore be sent in for stewing purposes. Very small holes pecked near the footstalks by tits some time since, and which have healed over, will sometimes keep fairly well, especially if the air is excluded from the wounds. Sealing wax dropped into these, or even a small piece of gummed paper such as frequently accompanies postage stamps duly plastered over, will frequently tend to preserve these slightly damaged fruits, which are too plentiful this season. Pears, unlike Apples, do not as a rule keep long after they are ripe, and it is not advisable therefore to store these in boxes, hampers, or heaps. The better plan is to place them in a single layer, stalk end uppermost, on clean benches or latticed shelves in a dry but not very airy room, where they can be frequently examined.

FRUIT FORCING.

PINES.—To maintain the sturdy, healthful appearance of young growing Pines, free ventilation is necessary, keeping the bottom heat about the roots at 80°, watering the plants whenever they require it, employing weak liquid manure occasionally, and avoiding the use of the syringe too frequently; merely sprinkling the paths, &c., morning and evening daily will suffice. Fire heat must be resorted to maintain a night temperature of 60° to 65°. Let newly potted plants have a bottom heat of 90° to 95°. Recently started suckers, as soon as roots are plentiful, can be raised near the glass, those intended to be watered in small pots being brought on gradually. Fruiting plants must have a night temperature of 70°; 80° to 90° during the day, closing at 85°.

When the suckers started this autumn are rooted, pot them without delay, draining the pots well. Employ the fibry part of turfy loam, and do not tear it up too fine, but use it in lumps proportionate to the size of the pots. The strongest plants may be transferred to the largest pots at once, the size being proportionate to the habit of the varieties. Jamaicas do well in 9 or 10 inch pots; Queens in 10 or 11 inch pots; Smooth-leaved Cayennes and similar varieties in 11 to 12 inch pots; and Providence in 12 to 13 inch pots, which will afford fruit of the largest size. Where smaller plants and fruit are required pots an inch or two less in diameter will answer. The plants that are not now fit for transferring to the largest can be shifted into 8 inch pots, in which they may be kept until spring, and then be transferred to a larger size.

CUCUMBERS.—The autumn fruiters must have careful attention, affording copious supplies of liquid manure, removing superfluous male blossoms and tendrils, avoiding overcropping, and not allowing the fruit to hang too long. Syringe only at closing time on bright afternoons. Earth up the roots as the plants advance in growth, from time to time.

Pinch out the growing point one or two joints beyond the fruit, examining the plants at least once a week for that purpose, retaining no more foliage than can be fully exposed to light. All water must be given at the same temperature as that of the roots.

Pot the plants from seed sown at the beginning of September for winter fruiting directly they are large enough, plunging the pots in bottom heat until the plants are established, then raise them near the glass, maintaining a temperature of 70° at night, 75° by day, with an advance from sun heat of 10° to 15°. The fermenting materials, if such are used for bottom heat, must be in preparation for the formation of the beds in due time. For producing a good supply of fruit in the late winter and early spring months sow seed at the beginning of October. Where the "disease" prevails it is a good plan to make frequent sowings, so that the succession may be better assured.

Plants in dung-heated frames or pits must have the linings renewed as required, the foliage being kept thin, the shoots stopped to a joint beyond the show of fruit, and no more water given than to secure healthy moisture for the roots, placing mats over the lights on cold nights.

STRAWBERRIES IN POTS.—A loose surface for Strawberries in pots prevents the soil leaving the sides of the pots, and admits of the water passing equally through the ball, and moistening it thoroughly. A little dried horse droppings or cowdung rubbed through a sieve applied to the surface will keep all right there. Remove all runners as they appear, also weeds, and do not allow the plants to suffer through insufficient supplies of water. The plants must have full exposure to light and air, allowing them plenty of space, to ensure sturdy growth and plump well-developed crowns. In the varieties required for early forcing, such as Noble, La Grosse Suerée, and Vicomtesse Hericart de Thury the crowns are plumping well, and the plants may, when required for early work, be plunged in ashes in cold frames, keeping them well up to the glass, the lights being withdrawn in all mild weather, only employing them in case of heavy rains, when they can be lifted or closed if frost prevails. As a first early we give preference to Noble, but we start along with it plants of La Grosse Sucrée and Vicomtesse Hericart de Thury, for Noble, though large, free in setting and swelling, has a colour which some do not like, and the flavour does not please all palates. La Grosse Sucrée is bright in colour, as well as large and free, with unquestionable quality; Vicomtesse Hericart de Thury sets and swells freely, and the quality pleases everybody—indeed, it is the very best flavoured of useful early Strawberries. We follow with Sir Joseph Paxton and President, both of which are in every respect excellent, and close with Sir Charles Napier, perhaps the most taking in appearance of all Strawberries; Auguste Nicaise and Unser Fritz, which are noble in size, and good in colour and quality, lead up to the finish and high quality of Dr. Hogg. In those we find everything desirable in forced Strawberries, also for outdoors, with the addition of Oxonian (syn. Eleanor). We have also a few King of the Earlies, which is readily forced, and though the fruit is small it is esteemed for jellies.

The autumn fruiters, if any are grown, should be encouraged with liquid manure—weak guano water or sulphate of ammonia, 1 oz. of the first and half an ounce of the latter to a gallon of water, and in the case of heavy rains and the fruit approaching maturity, the plants being placed in frames with abundant ventilation, which will improve the quality and colour considerably. Sir Harry as an abundant fruiter is unequalled, La Grosse Suerée is good, also Vicomtesse Hericart de Thury. Noble, though we have kept the forced plants, does not present any tendency to produce an autumn crop of fruit, but it has one prevailing characteristic which we have not noticed in any other variety—viz., the runners of forced plants push trusses of bloom after they become established in the small pots in which they are layered, or even when not layered, the smallest runners invariably throw a corresponding truss of bloom. Plants of the approved varieties that have been forced in spring, shaken out, repotted, and grown on are excellent for autumn and early winter fruiting, or if planted out and duly attended to they can be lifted at the end of September or early October, potted, and placed in a cold frame. Any autumn fruiters not required to fruit for some time yet may be retarded by placing them on a north border.

KITCHEN GARDEN.

CLEANING.—Winter is fast approaching. There are indications of it being unusually early, and all vegetable gardens will be much benefited by being thoroughly cleaned before they are saturated with moisture. Do not allow decaying vegetables to remain where they are growing, but place them in a heap to decay for manure. Clear all decayed leaves to the same heap, and above all remove the weeds that are producing seed.

STORING ROOTS.—Roots of all kinds should now be stored. The whole of the late Potato crop must be stored as soon as possible. The longer they are left the more difficult it is to dry them, and this is an important point, as when the tubers have to be dealt with in a wet state they are sure to deteriorate. Onions should now be in their winter quarters, and if Carrots and Beetroot are full grown they may be lifted and stored. They keep best in a place neither very dry nor very damp, the atmosphere of an ordinary shed will suit them as a rule. Beetroot must be carefully handled to prevent damage, and all roots keep better if not bruised. Those who have to send a large supply of vegetables to the kitchen every day during the winter know that roots form an important item in the demand, and the utmost attention should be given to insure the supply.

MUSTARD AND CRESS.—With us more of this is used in the kitchen than in the pantry, and the demand for it comes almost daily. Since April we have been growing it in the open air, but now it is too cold to do this, and it must be sown under glass. One of the best ways we have yet tried is to make up a gentle but firm hotbed, place a frame on this, fill it half way with any old rich soil, and sow the seed on the surface. A bed formed for the purpose now will produce crop after crop for two months or more, and it does not require more than three successional beds to keep up a supply throughout the winter.

PESTS AND YOUNG PLANTS.—We find slugs, snails, and other pests very plentiful this autumn. They soon injure and disfigure the young Cabbage Lettuces and other plants, and if not checked they will destroy them. A little lime or soot shaken over and around the plants once or twice weekly is a profitable practice, and may be continued until the plants have attained some size or become so hardy that the pests are less partial to them. If the soil is dry on the surface the Dutch hoe may also be run between the rows weekly with advantage.

ASPARAGUS.—The success of this if forced or left in the beds for next spring depends greatly on the manner the crowns are matured. If thoroughly ripened they will produce many good heads, although the roots are not of the best, and the surface of the beds should be cleared of weeds. If the stems are shading each other tie them up and do not remove any that are attached to the roots until they have become quite brown.

KIDNEY BEANS.—In the spring with proper appliances dwarf Kidney Beans will gain maturity in eight or nine weeks after sowing the seed, but at this season they will take twelve weeks or more, and those who wish to gather at Christmas and December should sow a quantity of Ne Plus Ultra seed at once in 3-inch pots and grow the plants in a gentle heat and plenty of light.

EARTHING UP CELERY.—The parts of Celery that are exposed when frost occurs often suffer, become soft, and will not keep well afterwards. It is therefore desirable that all Celery should be carefully earthed as far as possible without covering the stems above the centre, which may cause this to decay prematurely. One should hold the plants together and press the soil close to the stem while another pushes the soil forward with the spade; and after the whole has been done in this way tread the ridges all over very firmly so as to cause them to throw off the wet.

EARLY RHUBARB FOR FORCING.—Some of the Rhubarb crowns have nearly thrown off all their leaves, and the most advanced in this respect may be completely cleared to expose the crowns fully, and thereby prepare them for the first forcing a few weeks hence.

VEGETABLE MARROWS.—These are easily injured by frost, and a few degrees will render the plants useless. It will also affect the fruit in such a manner that they will not keep for any length of time afterwards, and as all the fruits that are young and tender now may be kept for several weeks after being cut, if secured in good condition, every one of them in this state should be taken in at once. If yellow and hard they will not be good for cooking, but anything short of this will prove useful. By putting them in a piece of net and hanging them up in the kitchen they may be kept in good condition until Christmas or later.

Do not allow winter Radishes to become crowded; keep the young Cauliflower plants hardy as long as possible by exposure; Lettuces that are of full size may be kept useful for a considerable time by lifting them with a ball of soil to the roots and placing them in a cold frame. The check received in lifting prevents their bolting. Cut and store Cauliflowers, and do not allow anything to remain exposed that is apt to be injured by frost.

PLANT HOUSES.

Poinsettias.—Be careful not to excite these plants into fresh growth. This often takes place after they are removed from cold frames by maintaining too light a temperature and too close an atmosphere. Air may be admitted liberally on all fine days, but be careful to avoid cold draughts. Employ fire heat to maintain a night temperature of 55° to 60°. Water the plants with care, and use for them water slightly warmer than the temperature of the house. Euphorbias, Linums, Plumbagos, Justicias, and other similar plants will require the same treatment.

Begonias.—These are likely to suffer from damp if kept in cold frames or cool structures any longer. They will do in the same temperature as advised for Poinsettias, only more liberal ventilation may be given during the day. Keep the atmosphere much drier than is necessary for those plants. For some weeks longer we shall keep plants of the *B. manicata* section cool, using fire heat only when the temperature falls or shows signs of falling below 45°. Let all watering be done in the morning, so that the atmosphere will become dry before the ventilators are closed in the afternoon. *B. Ingrami* and the old *B. semperflorens* are now being placed into 4-inch pots. The latter will be allowed to come into flower, and later plants now in small pots on a shelf close to the glass will be grown on to succeed them. In a temperature of 60° they grow quickly. The best of the early flowering varieties will be retained for flowering again. They can be kept in the same pots, and assisted by the aid of artificial manure. *B. nitida* and its variety *rosea* will be useful presently either for the stove or an intermediate house if allowed to come into flower. The same may be said of *B. Ingrami*, *B. Knowsleyana*, and the coloured forms of *B. semperflorens*. Such Begonias as *B. weltoniensis* and *B. parvifolia* may be placed in a cool house, kept dry, and allowed to rest.

Gardenias.—Plants that have not yet set their buds need not be kept in a higher temperature than 60°. If too warm and too moist they are liable to start again into growth, which has no chance of being ripened thoroughly, deformed flowers resulting. Strong insecticides should not be used for syringing plants that have formed flower buds, as they are almost certain to turn yellow afterwards. Plants that have buds swelling freely may be pushed forward in a temperature at night of 65° to 70°. If the plants are grown in pots, and can be given slight bottom heat, such as a bed of leaves afford, all the better.

Eucharis.—Some care is needed at this season of the year where numbers of plants are grown. They are liable to show flower, and though a few are always useful when quantities are produced at one time it frequently happens that many are wasted. If plants that have completed their growth are removed to a temperature of 50° they can be kept back for a long time without the slightest injury. The soil should be somewhat dry at their roots before removal, and water must be supplied with great care while they are in a lower temperature. The plants are not injured by a lower temperature provided cold draughts are not allowed to reach them.

Stephanotis.—Plants that are intended to flower early should be taken from their trellis and thoroughly cleaned. What pruning is needed may now be done, the soil kept rather dry, and the temperature at 50°. To grow these plants well it is important that they enjoy a complete period of rest.

Allamandas.—These will grow throughout the year if they are encouraged by heat and moisture. Plants that are needed for early flowering should be induced to rest by placing them in a lower temperature and a drier atmosphere. Water may be withheld until the plants flag. Sufficient, however, must be given to prevent the wood shrivelling. *Clerodendron Balfourianum* and *Bougainvilleas* may also be induced to rest.

NOTES ON BEES.

QUEENS FOR NEXT YEAR.

IN addition to having all stocks of bees supplied with ample stores this month, no pains should be spared to make sure that every stock has a young and fertile queen; without that nothing but disappointment will follow next spring and autumn. Many stocks swarmed this year at the Heather, and owing to the sunless weather few of the young queens are fertilised. After an unfertilised queen commences laying, and until the brood is sealed, it is difficult to know by appearance whether she is fertilised or not. A test by which I can discriminate her state is to catch her by both wings, when if unfertilised she contracts her abdomen to very small dimensions, whereas if fertilised the abdomen round the ovaries retains much of its usual dimensions.

TARRING THE INSIDE OF HIVES.

Absorbing or porous hives lately formed an absorbing topic. Some of their advocates seemed to lose sight of the fact that absorbing material could store only a certain quantity of moisture. Plaster of Paris, one of the ingredients recommended, becomes so saturated with moisture as simply to become a wall of water, which as it absorbs gives off moisture so as to seriously affect the health of the bees and destroy the combs and honey.

Double walled hives have a similar tendency, and moreover decay sets in at the angles in a short time after the bees are put in them. As a guard against decay and damp I have for some years tarred the inside of all my double cased hives, in every instance to the great advantage of the bees, demonstrated to a greater extent this year than at any time previously.

DAMP IN HIVES.

Nothing injures a hive so much as damp, whether it arises from internal or external causes. It is now a fitting time to repeat, for the sake of novices, that non-porous material on the top of hives is a great mistake, as also is placing watertight or non-porous material close on the top of porous material. Place porous non-conducting material on the body and crown of the hive in sufficient quantity that the atmosphere cannot conduct the heat from the hive, and over that an impervious roof or covering some distance

from the packing, with sufficient ventilation to carry off all moisture as it escapes from the bees through the packing. A narrow doorway and a proper ventilating floor, together with what is advised above, is all that is necessary to provide or do till April or May, or if all is favourable till June.

RAISING PARTLY FILLED SUPERS ABOVE EMPTY ONES.

We have advised the placing of empty supers above partly filled ones for upwards of thirty years now, and although at times the contrary has been successful, still it is not in accordance with the best management. It is only a haphazard way. I have scarcely ever practised it, and only once did I succeed in getting things to my mind when the empty super was placed beneath the full one. To be successful the weather requires to be exceptionally fine and uninterrupted for some weeks, which is rare in this country. Circumstances compelled me to put the empty supers beneath the partly filled ones at the Heather this year, which has resulted in the bees carrying some of the gathered super honey down to the body of the hive, and filling the body boxes thoroughly with it and the subsequently gathered honey. I need not have expected it otherwise, as the weather never was settled during the whole month of August. I give the failure as prominent as my successes as a warning to others. Had the weather been fine during the latter part of August, when the Heather was in bloom, every available space would have been filled, and the error of placing empty supers between partly filled ones and the crown of the hive would never have been observed. Experience has long taught us that nothing is gained by placing the partly filled supers uppermost, but often much is lost.

THE HEATHER SEASON.

I have observed "A Hallamshire's" remarks, pages 276, 277, regarding the Heather season. Where I took my bees from the 7th of July until the last day of August there was not a single day upon which rain did not fall. Previous to that the weather had been exceptionally fine from April 1st, very little, if any, frost until the morning of the 23rd July—a rather unusual occurrence. The first six days were dry and warm, but always with rain at night. Monday the 12th and Tuesday the 13th of August were the most productive of honey the bees had, but rain fell on both days. The latter was the day in which the greater gathering occurred, and was that when the hive gathered 38 lbs. After the 13th the weather gradually became more rainy, and less honey was gathered daily. The first week in September was dry and warm, but the bloom had nearly gone from Heather, and very little more honey was gathered.

Some people complain they cannot get their bees to take to supers. I have never any difficulty in that. The difficulty is to keep them in them, and that can only be accomplished when the weather is favourable. In such a season as the present has been the bees leave supers and store the body of the hive; the lowering of the temperature is the cause of this, and is explained by the fact that supers are extra room; the bees on the temperature lowering retreat towards the brood nest and cluster there, and as the hive becomes filled draw nearer the doorway.

My good hives, after the hatching of the brood and other losses from consumption and evaporation, &c., stand about 80 lbs. heavier than they were when set down, but the supers are in many cases unsealed. An octagon hive filled completely four supers, but are deficient in weight 25 lbs., and incomplete, although otherwise good. My weaker hives have risen in weight from 10 to 20 lbs. only, but were capable of rising 50 lbs. easily had the weather been settled—a strong argument in favour of having strong hives; and what a boon it would be could we discover some method to prevent swarming and still keep the hive in a normal condition. He who gives us the information will be a benefactor indeed.

It is customary for bees to swarm at the Heather even up till the middle of September, and rarely will a strong stock supersede

the queen regnant without swarming. Sometimes very few bees leave and may not be observed. Regarding the ripening process, I disagree with many writers upon this question. I always held the opinion that extracting the water takes place while the bee is sipping it from the flower while on the wing, and being lighter than honey is evaporated from the hive by the heat of the bees, so great sometimes this year that I have witnessed the vapour ascending from the sides of the hive when rain fell upon them, and the vapour issuing from the mouth of hives illustrates my idea. Therefore I differ in opinion from "A Hallamshire Bee-keeper" regarding bees being able to ripen the honey they gather daily, even although it be greater than the quantity gathered by my strong stocks. The more honey a colony of bees gathers in a day the better able they are to ripen it—if the term is a proper one, it sounds harsh in my ear. In fact, a hive able to gather 33 lbs. a day is better able to evaporate the excessive moisture than one able to gather 1 lb. daily only. I have repeatedly watched bees storing honey as they came from the fields, and it never underwent any other process than the first storing, and the supposition that as the water rose on the top of the honey the bees sipped it off, the work of a few seconds only.

THE PUNIC BEE.

Although the Punic bees have not excelled at the Heather they seem assiduous workers at home, and may by another season prove themselves good honey gatherers.

YOUNG QUEENS.

It is perhaps not out of place to bring before your readers the doings of a young queen fertilised about the 7th September, showing how completely it sets at defiance all the theories of "breaking seals of honeycomb," "stimulative feeding," or "contracting or spreading the brood, &c." In ten days' time she laid nearly 30,000 eggs, the only thing conducive to this is what I have so long advocated—namely, having the hive well stored with honey and pollen. It would be interesting to know what those think of this that say "a queen must be some months old before she is at her best."

ERRATUM.

At page 255, second article, last line but one, instead of "several ombs," read "several hundredweight of wax."—A LANARKSHIRE BEE-KEEPER.

* * * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

List of Gardeners (J. L. G.).—There are numbers of small local improvement societies, but nothing of a general character, though you can obtain all the information you require from the "Horticultural Directory," published at this office, price 1s.; post free, 1s. 3d.

Bluebottle Flies in Conservatory (J. C.).—We can only suggest their destruction by suspending soda-water or similar bottles half filled with beer, made very sweet with sugar or syrup, near their haunts. The flies, we presume, are attracted by the secretion emanating from insects infesting the plants, the flies being very partial to the

excrementitious matter of the scale insects. If the plants are infested with insects they must be destroyed, and then the flies will cease their attentions.

Improving Old Orchard Trees (J. J. C.).—As you say manure is scarce, you perhaps cannot do better than follow the practice described by Mr. J. Wright on page 237, which so well answered the desired purpose. It is also recommended by Mr. Tonks in our present issue. The best Peruvian guano is good for the purpose, and may be applied at the strength of an ounce to each gallon of water, after the earth has been previously moistened to a depth of 2 feet with pure water. For assisting its penetration holes may be driven down with an iron rod here and there, and these filled repeatedly with water, and subsequently liquid manure. Information relative to the analyses of soils can be obtained from the Secretary of the Royal Agricultural Society, Mr. Ernest Clarke, 12, Hanover Square, London.

Vines Unsatisfactory (Constant Reader).—The roots are probably in an unfavourable medium, the border being wet, close, and cold, the roots at a considerable distance from the surface. We suggest that the surface soil be removed down to the roots, and some of it removed from amongst them, lifting and laying in fresh loam with an admixture of one-sixth old mortar rubbish, and a sprinkling of crushed bones. This should be done now whilst the leaves are on the Vines. The roots should not be covered deeper than 3 or 4 inches with fresh soil, and they should be mulched with leaves about 6 inches thick, with a little litter on top to prevent their blowing about. The drainage must be examined, and if defective rectified. The only alternative course is to allow more lateral extension of the Vines, which by encouraging root action will, to a certain extent, counteract the tendency to defect of colour, and be serviceable against shanking.

White Pinks for Forcing (B. R. S.).—Some time ago a correspondent gave the following description of a method he had found successful:—"During the first week in October we look over our elumps, and choose such as are most compact and are then showing a number of small fibrous roots at the base of the season's growth. Some plants appear to emit roots much more freely than others, hence our care in selecting. Cutting them off with 2 or 3 inches of old stem will ensure having a cluster of growths on each piece. According to their size place two, three, or four together in a 4 or 5-inch pot, which may form one bushy plant. Place them in a shady position or cool frame for a few weeks, when the small hair-like roots soon commence growing, and by the middle of February reach the pot sides. If the plants have had a cool airy position sheltered from heavy rains and frost they may be introduced as required into gentle moist heat, and will give a good supply of bloom from Easter onwards. Some other Pinks may be flowered under the same treatment, though not quite so early, nor are they so valuable as the old white."

Euphorbia jacquiniæflora (M. T.).—Plants that have been in cold frames up to the present time must be removed to a house or pit where the atmosphere can be drier at night, and the temperature at about 55°. If left in cold frames after this date the foliage is very liable to turn yellow, especially if too much water is given at the roots. If removed to a heated structure care must be taken that the plants are not excited again into growth, or they will soon become tall and weak, and in the end flower but poorly. To avoid this no artificial heat will be needed for some weeks yet during the day, and only at night when the temperature is likely to fall too low. On all favourable occasions air should be liberally admitted during the day as well as at night. If the pots are full of roots stimulants may be given in a weak state every time water is applied, nothing being better for these plants than liquid made from cow manure and clear soot water. If the plants display any signs of starting into growth feeding must be discontinued for a time, at least until this tendency is checked.

Constructing Tomato House (J. Williams).—The height at the sides is of no consequence. It may be 18 inches, so as to admit of side ventilation, and all you want in that case is sufficient head room in the centre, about 8 feet 6 inches from the floor to the ridge being necessary. The pathway may be sunk, which will save having so sharp a pitch, which will of course, as regards length, be proportionate to the width of the house. An angle of about 45° would be suitable. A width of 9 feet to 10 feet 6 inches would be suitable, and the length could be corresponding to the requirements or means. Provision should be made at the top of the house for ample ventilation. There are other houses of an economical kind, in which the sides can be of wood to a height of about 4 feet 6 inches, with a board opening the whole length on both sides for ventilation, similar provision being made at the top of the house. The width of the house ought not to be less than 8 feet 6 inches, which will allow of a 2-feet 6-inch pathway and a 3-feet border on each side. It may be any greater width, and in respect of the pitch of the roof it may fall or have incline of 1 foot in every yard of width.

Treatment of Narcissus in Pots (G. W.).—It will be quite safe to leave the bulbs plunged in the ground and covered with ashes, sand, or cocoanut-fibre refuse until the close of December or later. They will probably be advanced in growth, which will not be injured, as they are hardy. It is advisable, however, to afford protection in severe weather, nothing answering better than a single or double thickness of mats, kept clear from the growths by a framework of laths, removing the mats in mild weather. The night temperature is quite high enough, and the day also by artificial means, but keep them near to the glass, and afford air on all favourable occasions. In fine weather the growths may be sprinkled daily, but it is more important to maintain a genial

condition of the atmosphere by damping cool, not heated, surfaces when they become dry. The water draining from pots in watering will be sufficient in most cases during severe weather, as a saturated atmosphere is not then desirable. Stand the plants outdoors as soon as the weather becomes sufficiently settled, as it will by the middle of May, and a sheltered situation being chosen they will mature much better than if they were kept under glass until the middle of June. If they can be hardened a little before being placed out it would be an advantage. Plunge them in ashes outdoors, and afford plenty of water and liquid manure occasionally when they are in full growth, and up to the foliage showing signs of becoming yellow for ripening, when it will suffice to keep the soil moist. Early potting is very desirable, the time you name (early August) being good, and plunged in ashes to the rim of the pots they could remain outdoors as long as you desire, only before frost it would be advisable to cover with 3 inches thickness of cocoanut-fibre refuse. Nothing is so injurious to Daffodils as keeping them out of the soil and not planting until late, or when those left to Nature would be well furnished with fresh roots.

Increasing Deutzias (S. T.).—If it is necessary to increase the stock of these for another year's forcing, strong plants may be lifted from outside borders and potted at once. Many lift these plants and force them the same season, but this is a mistake, for they should be established in their pots for one year before forcing them into bloom. If placed at once in 6 to 8-inch pots, according to their size, they will become partially established before the foliage falls, and will make splendid plants for another year. They can stand outside until the approach of severe frost, when they should be pruned and the pots plunged in a cold frame. If allowed to start into growth and are encouraged in cold frames until June they will be ripened early, and in a fit state for forcing into bloom early in the season. It is a good plan to lift a few plants annually from the outside for potting, and then the stock of these plants can be kept in admirable condition. Plants that have been weakened by forcing may now be turned out of their pots and have their roots reduced by one-half and repotted in fresh soil. These if given cold frame treatment will thoroughly recruit themselves in a season, and be in the best condition for forcing. A portion of our stock is subjected to this treatment annually, and by this simple method the whole of the plants are kept in good condition. Plants that die or do not start freely into growth are replaced by new stock from the borders. The plants for this purpose are raised by striking cuttings in heat in spring, placing them singly in boxes 2 inches apart, and afterwards planting them out.

Gas Lime for Ground to be Cropped with Potatoes (J. E. P.).—We use gas lime on ground intended for Potatoes alike as a preventive of attack by vermin and fungi. The gas lime is from our own works, the gas being manufactured for lighting the mansion, stables, &c., driving engine for pumping, &c., consequently we have gas lime always available. The best time to apply it is to ground to be cropped with Potatoes in October or November before the ground is dug or manured, and at the rate of half a bushel per rod (30½ square yards). The gas lime is disposed as evenly as possible on the ground, and either lightly hoed or pointed in with a fork. At that time vermin and fungoid germs are on or near the surface, and more readily available for attack, and any injurious effect the gas lime may have passes off by exposure to the atmosphere; in fact, passes quickly into the gypsum state, in which it is not a despicable manure. After lying a month or so the ground is manured if necessary, the gas lime being buried in the work of forking or digging. In spring, before the Potatoes are planted, we occasionally use the gas lime again, particularly for ground that has not previously or recently been dressed with it, and at the same rate as in the autumn, spreading it evenly on the surface, and leaving it there for at least a month before "setting" the Potatoes. This, however, is only practised when the ground is foul with slugs, &c., as the full application of gas lime—viz., 1 bushel per rod, should only be had recourse to when the soil as shown by the attacks on the crops is extremely foul. As to the beneficial effects of dressing with gas lime as a preventive of scab, we can only state that on some ground which three years ago gave scabbed crops, the Potatoes are this year free, the land having been consecutively cropped with Potatoes, which in this particular instance is a necessity. It is not, however, sound practice to follow Potatoes on ground that produce scabbed tubers, nor to use "seed" tubers that are scabbed or taken from an infected crop. Necessity, however, precludes choice, and it is not certain that the ground is at fault, as tubers show no trace of scab at lifting, but during the winter it develops, and they become much deteriorated in value, the quality being invariably good. Scabbing does not always arise from the attacks of a fungus, as in some instances there is no trace of the action of fungi, and in such cases may arise from corrosive substances in the soil.

Names of Plants.—We only undertake to name species of plants not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (J. M.).—1, *Solidago virga-aurea*; 2, *Begonia semperflorans*; 4, *Euonymus japonicus variegatus*; 5, *Pachyphyton bracteatum*. The others were insufficient for recognition. (A. T. M.).—Send a better specimen with flowers. (W. R.).—1, *Aphelandra cristata*; 2, *A. aurantiaca*.

Michaelmas. The drains can very well wait till winter, but now we must turn every hour of fine weather to account to get as much of the land broken up as we can, and we must endeavour to do this in the right way. Walking recently over a heavy land farm with an advocate of shallow ploughing we saw a lot of the common Bindweed (*Convolvulus arvensis*) on a bare fallow, which had been left during harvest long enough for growth to appear well above the surface. The thick fleshy roots of the Bindweed had remained undisturbed in the soil near the surface, all through the "summering" of the land, simply because the ploughshare never entered more than 2 or 3 inches into it. There was the enemy left undisturbed to send up growth and enfold the stems of the next corn crop in its baleful grasp. The remedy was deep ploughing followed by a grubber, and a cultivator or duck-foot harrow pricking up every root by hand again and again after each turn of the implements. The Suffolk duck-foot harrow is an invaluable implement for thorough cultivation. In point of fact it is a light cultivator, with the tines curved forward and flattened at the ends, so as to sever roots as well as dividing the soil. It is of simple construction, strong, yet of very light draught, and is not to be regarded as a mere cleaning tool, but as one of the best tillage implements.

We have said that when a farm comes in hand from a tenant under the covenants of old agreements a certain proportion is invariably bare fallow. As a matter of expediency this is sown with winter corn, light harrows only being used before the drill. However fair to the eye the fallow may be its actual condition is always doubtful, and if the weather is favourable a turn or two of the duck-foot may have a favourable influence upon the Wheat crop as well as bring a lot of couch grass to the surface. A well managed fallow should be innocent of perennial weeds, but how frequently are they mismanaged. Very seldom can the number of ploughings and harrowings be taken for an assurance of thorough cultivation. If a proper interval had been allowed between each time of stirring the soil, grass and other weeds would have been destroyed in a fine summer, but it is not often that an outgoing tenant pays much attention to the interests of those who come after him upon the land, and fallow ploughing is but too often done when convenient and not when necessary.

To an experienced eye the manner in which autumn tillages are done affords a tolerably clear indication of subsequent results. Every foul stubble should be pared with broadshares if they can be used, then with light harrows all the surface weeds can be got out and burnt. A few turns with the duck-foot next will bring other weed roots to the surface, and then it requires some judgment whether to plough and follow with a grubber or cultivator or not. The object of autumn tillage is to clean the land as quickly as possible, and this must be done in accordance with the state of the weather and condition of the soil. We want the land clean, dry, and thoroughly disintegrated before it is cropped; that is our aim before all things, and we can for the moment leave out all thought or care about fertility, as we can impart that at will at any time by means of chemical manures. When land is intended for spring cropping disintegration is a certainty if we finish our work now by throwing up the land into high ridges with a double-breasted plough. With sound under drainage, taking all superfluous water away quickly, no matter how wet a winter may follow, the soil remains dry in the sense of being free from any hurtful accumulation of water in it. Frost, snow, wind, and rain all have a beneficial effect upon it, and in spring it is in the best possible condition to receive manure and seed.

But we may be told that to thus do all we can to break up the land now and to ridge it for winter leads to a loss of nitrogen. Have not the Rothamstead experiments proved this? Yes, they have; but we have ample compensation for such loss in our deep, fine, clean seed bed, and we know too that air does not circulate freely in soil without imparting some degree of fertility to it, so that it is a clear case of give and take with very much in

LANDLORDS' FARMING.

ALTHOUGH drainage has been mentioned as of primary importance in reclaiming poor land, yet tillage in reality comes first at

favour of the take. No doubt it requires some experience to enable one to manage tillage in the most direct and thorough way, so as to economise labour, and yet do all that is necessary; but even a beginner cannot go far wrong if he acts upon the lines indicated and resolves that, come what may, his tillages shall be both deep and thorough. If he does this he has certainly taken the first step towards improvement. Whether it may eventually lead to profitable results depends upon very much more than this, and we have next to consider our course of cropping, and to try and see whether it will answer best to keep the land under a regular four or five course shift or to lay it down for a few years.

(To be continued.)

WORK ON THE HOME FARM.

Change of food tends to promote health in all animals, and is of especial importance for sheep. The ewe flock is now upon the last stubbles, with a change to Sainfoin and pasture, and on the whole it is healthy. The exception is present in frequent cases of foot-rot, which are kept from becoming bad by constant attention. Much depends upon the shepherd in keeping down this contagious disease, and if he becomes at all negligent he cannot conceal it, for not only do lame sheep multiply, but there is a rapid falling off in condition of all the badly affected animals. We recently heard it questioned if foot-rot were infectious, and we repeat that we proved it to be so many years ago. We are using both shearling and lamb tups this season of necessity, and not of design. We always prefer the younger tups, but the purchase of fresh tups yearly becomes a serious item if really well-bred animals are required. It is well to change them daily in all large flocks, and to feed them well always. Many flock masters prefer to tup with the flock upon White Turnips; well, we have no objection, but it is mere prejudice that could see any advantage in such a plan, which doubtless had its origin upon large corn-growing farms, where it answered to sow Turnips as early as possible, simply because there was so little pasture. The risk of thus having to depend upon so uncertain a crop is obvious, and much inconvenience must follow in an unfavourable root year. Lambs at all forward are approaching the hogget stage, and it answers well to push them on with plenty of trough food when they leave the stubbles. This food need not contain any cake, but may consist of crushed home grown corn. Oats, Peas, Beans, and Barley may often all be so turned to better account than to be sold as corn. A field of early Turnips folded off now will be available for Wheat, and the sheep are all the better for being upon the arable land so long as it continues firm enough for folding. But they must be withdrawn if very wet weather sets in, for no sheep can continue to thrive in such mud puddles as they are often kept upon in winter, with mud half way up the legs and nothing but mud to lie down upon. Under such conditions the strain upon the frames of the strongest must be very severe.

REVIEW OF BOOK.

The Book of the Farm. In six Divisions—Division III. By HENRY STEPHENS, F.R.S.E. Fourth Edition. Revised and in great part re-written by JAMES MACDONALD. Blackwood & Son, Edinburgh and London.

UNDER the heading of "Practice—Spring," the third volume of this very practical work contains—Cattle in Spring, Sheep in Spring, Manures and Manuring, and Seed-time. Each subject is treated fully, not from a particular point of view, but by a series of deductions from the best practice generally, and the high character of the work is well sustained. To give some idea of the exhaustive manner in which each subject is treated we may take that upon calving and calf-rearing, to which are devoted some 160 paragraphs, each under its distinctive heading. In no other work have we seen such a fund of sound practical information upon this subject, and the fact of the heading of each paragraph being given in a table of contents makes reference easy, and adds materially to its utility.

The treatment of sheep in spring points naturally to the lambing season, and the entire process of lambing with its attendant risk is fully discussed. The views given of some of the best flockmasters upon abortion are of special value as affording direct information of its cause and how to avoid it.

In his introduction to the important section of manures and manuring the able reviser says, "In the advanced agriculture of the present day the question of manuring possesses far more importance and involves greater difficulties than were associated with it in the elementary farming of olden times. The extension and accumulation of knowledge in regard to the maintenance, utilisation, and recuperation of fertility; the discovery and development of new sources of manurial commodities; and the vastly increased and still growing consumption of farm produce of all descriptions have, with their combined influence, contributed largely to the great revolution which, since 1840, has taken place in British farm practice. The farmer can no longer wait for the recuperating power of Nature to restore reduced fertility. He is not content to merely "turn over," as it were, the natural store of plant food which the soil possesses. Before the advent of artificial manures and feeding stuffs the prevailing system of farming was little else than a turning

over of the inherent fertility of the soil—the abstraction of fertility from one field in certain crops, and the returning of it, or a great part of it, to another field in the shape of farmyard manure. This, however, was a slow process, quite unequal to the wants, the aspirations, and resources of the progressive age in which we live. A speedier, more intense, more artificial system of farming has arisen, and to make provision for the greater demands which are now made upon the productive powers of the soil active and persistent attention has for years been devoted by scientists, capitalists, and practical farmers to the all-important question of *manuring*.

"By the discovery of vast natural deposits of manurial elements and by the manufacture of useful fertilisers from waste products and other material, great possibilities, hitherto undreamt of, have been placed in the hands of the farmer. By the means of these agencies it is possible for him to vastly increase and hasten the production of his farm, not only by adding to the supply of plant food already in the soil, but also by so stimulating, equalising, and preparing that supply as to render it far more serviceable and nutritious to the growing crops."

For this and other cognate reasons he goes on to explain why exceptional attention and space have been given to the subject in this volume, and why he has taken to his aid the writings of our most eminent chemists and practical agriculturists. He then deals with the exhaustion and restoration of fertility in the soil, the manufacture and use of farmyard manure, and artificial manures are classified in groups as nitrogenous, phosphatic, potassic, and calcareous manures. Much valuable information follows of the application of manures, and then we have the Rothamsted, Aberdeen, and Sussex experiments and results, with those of the Highland and Agricultural Societies, given with sufficient detail and fulness to render them of real practical utility to every earnest intelligent reader.

Under "Seed Time" the cultivation of spring corn is treated in all its various aspects of soil tillage—the varieties, preparation, and sowing of the seed. Permanent pasture hardly has the attention it deserves. Descriptions of Grasses and Clovers are taken from Mr. Martin J. Sutton's great work on permanent pastures, and some useful lists for layers of from one to seven years' duration are given. The diagrams showing the influence of drainage and tillage upon seed germination are of especial value, and the few paragraphs on "Forage Crops" which follow bring this valuable addition to agricultural literature to an end. We certainly regret space should not have been found in it for a few emphatic hints upon the importance of pasture cultivation, about which such general remissness prevails, for it is more than ever desirable that every acre of land under cultivation should be rendered as profitable as is possible.

OUR LETTER BOX.

Winter Dietary for Channel Island Cows (*A Subscriber*).—

Let the best meadow hay be given three times daily, only as much as the cows can consume being given each time. A little watchfulness will soon show how much they require. At milking time both morning and evening give each cow 3 lbs. of a mixture of equal parts of bran, crushed oats, decorticated cotton cake, and Smith's palm nut meal. This dietary is sufficient, but if you have any Carrots or Cabbages a few may be given till Christmas, and a little Mangold may be used in the new year. You ask for the best and cheapest way of feeding in winter, and we may remind you that the cheapest way is not of necessity that which costs the least, but which gives the best return upon expenditure. The best way also is that which induces a full flow of milk that is entirely pure and sweet.

REMARKS.

22nd.—Fair morning, overcast at times, but generally fine; bright night.

23rd.—Overcast cold morning; dull day and night.

24th.—Dull damp morning, with heavy rain; dull evening.

25th.—Fine morning, day, and night, with fresh breeze.

26th.—Bright sunshiny morning, fine day and night.

27th.—Dull and overcast, slight rain; fine day and night.

28th.—Fair, but rather dull all day.

Temperature slightly below the previous week, and about 2° below the average.—G. J. SYMONS.

ROSE ANALYSIS.

1886—1889.

TAKING down the names of the Roses at the National Rose Society's Exhibition at the Crystal Palace proved this year no easy task, owing to the number of visitors and the very limited area into which the Show was crowded. Thanks, however, to the kind assistance given to me by several exhibitors and other friends, to whom I must here express my great indebtedness, but few stands were missed. For the purposes of our analysis this is extremely fortunate. The three previous Rose seasons having been unusually late ones, a very forward summer like that of the present year was much needed in order to help to keep the balance true between the early and late varieties; it is therefore a matter for congratulation that a sufficiently complete record of the Roses in the prize stands at this Show should have been secured.

Before proceeding to consider the tables more in detail it may be well to explain once again the system upon which they have been compiled. All those varieties which were sent out prior to 1883 find places in the analysis according to the average number of times they were staged at the last four metropolitan Exhibitions of the Society. In the case of those Roses introduced during that year their average for the last three Shows is alone taken into consideration, for those of 1884 their average for the last two Shows only, while the positions accorded to the still newer sorts are entirely dependent upon how they were represented at the Exhibition this year.

The number of Roses tabulated in each of the four years has been as follows:—

	HYBRID PERPETUALS.	TEAS AND NOISETTES.
1886.....	1038	509
1887.....	1130	642
1888.....	1247	854
1889.....	1176	778
	<hr/> 4591	<hr/> 2783

Coming now to the table of Hybrid Perpetuals it is interesting as usual to notice how certain seasons favour certain Roses. For instance, at the Crystal Palace this year Captain Christy appeared in no fewer than forty-two stands, or in a greater number than any other H.P., whereas in 1887 it was to be seen in only eight. Alfred Colomb also took a good position, its average record for the previous three shows being eighteen, while this year it was set up in as many as thirty stands. Among other varieties specially favoured in one way or another by the past summer may be mentioned Merveille de Lyon, Comtesse d'Oxford, Marie Finger, Pride of Waltham, Reynolds Hole, Star of Waltham, Pierre Notting, Charles Darwin, and Queen of Queens. On the other hand Madame G. Luizet was much less frequently shown than usual. Nevertheless, owing to its very superior form in the three previous years it still manages to hold the premier position in the analysis, having been staged no fewer than 145 times at the four exhibitions. Lady Mary Fitzwilliam, Baroness Rothschild, Etienne Levet, Le Havre, Sénateur Vaisse, Duke of Edinburgh, and Général Jacqueminot were also indifferently represented. Duke of Edinburgh, for instance, is evidently not a dry or hot season Rose, for this year it appeared in only eight stands against thirty-three in the cool and wet summer of 1888. This would also seem to be the case with Général Jacqueminot and Etienne Levet. Marie Baumann, A. K. Williams, La France, and François Michelin were almost equally

well shown in each of the four years, but the same can be said of but few varieties, nearly all being more or less at the mercy of the seasons.

The following Roses were this year exhibited about twice as frequently by amateurs as by nurserymen:—Madame G. Luizet, La France, François Michelin, Marie Finger, Captain Christy, Louis Van Houtte, Marie Verdier, Camille Bernardin, and Dr. Andry. Whereas those sorts which as greatly predominated in the nurserymen's stands were Lady Mary Fitzwilliam, Xavier Olibo, Comtesse d'Oxford, Ferdinand de Lesseps, Reynolds Hole, and Queen of Queens.

Very few new Hybrid Perpetuals find places in the analysis. Of those sent out in 1884 the only representative is Victor Hugo, and this has rather lost than gained ground since last year. Her Majesty, which was first distributed in 1885, has already proved itself a splendid exhibition Rose. In fact at the Crystal Palace this year there were only three other H.P.'s more numerous shown—Captain Christy, La France, and Merveille de Lyon. The year 1886 is altogether unrepresented. In 1887, however, appeared Earl of Dufferin, Mrs. John Laing, and Silver Queen. The Earl of Dufferin now stands at No. 25, Mrs. John Laing at No. 29, and Silver Queen at No. 44 on the list. I am not as yet a very ardent admirer of the Earl, but could not well speak in too glowing terms of Mrs. John Laing, which is certainly the finest Rose of recent introduction. It may be noticed in passing that four out of the five new varieties above mentioned were raised in the British Isles—Her Majesty and Mrs. John Laing by Mr. Henry Bennett, and Silver Queen by Mr. William Paul in England, and Earl of Dufferin by Messrs. A. Dickson & Sons in Ireland.

Catherine Mermet still stands at the head of the list of Teas and Noisettes owing to its consistently good form at the last three exhibitions. The most prominent variety this year, however, was that superb but somewhat fickle beauty, Comtesse de Nadaillac, which was staged as many as fifty-seven times, or more frequently than any other Rose in the Show. Niphetos, Madame de Watteville, Jean Ducher, Madame Cusin, Princess of Wales, Francisca Krüger, and Madame A. Jacquier also appeared in more or less unusual force. On the other hand, as might have been expected in so early a summer, Maréchal Niel was to be seen in but few stands—fourteen against forty-four in 1887. Madame Lambard, as a show flower perhaps the most uncertain member of its race, was shown in only twelve stands, whereas last year it was to be seen in fifty-one. Again, Marie Van Houtte was staged only eighteen times, but in 1888 fifty-seven times. Anna Ollivier was also seldom exhibited.

As regards the newer varieties, Souvenir de Gabrielle Drevet (1884) is evidently a cool season Tea, for although a year older it was much less frequently shown at the last Exhibition than at the previous one. The Bride, which first appeared in 1885, has already reached the fourth place in the analysis, having risen no fewer than eleven difficult steps since last year. As in the case of the H.P.'s, there is no Tea or Noisette to represent the year 1886. The only other new variety is Ethel Brownlow, which was sent out in 1887, and now stands at No. 24. Of these three new Tea Roses there is but one which came to us from France—Souvenir de Gabrielle Drevet. The Bride sported from Catherine Mermet in America, while Ethel Brownlow was raised by Messrs. A. Dickson & Sons at Belfast.

I again append a select list of Roses that may be recommended for general cultivation, and yet which are at the same time among the very choicest of our exhibition Roses.

HYBRID PERPETUALS.—*Light-coloured Varieties*—Madame G. Luizet, La France, Merveille de Lyon, Captain Christy, Marie Finger, Baroness Rothschild, Mrs. J. Laing, and Marguerite de St. Amand. *Medium Reds*.—François Michelin, Ulrich Brunner, Marie Verdier, Marquise de Castellane, Camille Bernardin, Comtesse d'Oxford, Dupuy Jamain, Heinrich Schultheis, and Suzanne

Marie Rodocanachi. *Reds*.—Marie Baumann, A. K. Williams, Alfred Colomb, Prince Arthur, Le Havre, E. Y. Teas, Ferdinand de Lesseps, Sénateur Vaisse, and Earl of Pembroke. *Dark Varieties*.—Charles Lefebvre, Louis Van Houtte, Horace Vernet, Duke of Wellington, Duke of Connaught, and Sir Rowland Hill.

TEAS AND NOISETTES.—Innocente Pirola, Souvenir d'un Ami, Caroline Kuster (N.), Marie Van Houtte, Madame de Watteville, Hon. Edith Gifford, Madame Lambard, Anna Ollivier, Francisca

Krüger, Rubens, Souvenir de G. Drevet, Perle des Jardins, Souvenir de Thérèse Levet, and Souvenir de S. A. Prince.

HYBRID TEAS.—Grace Darling and Viscountess Folkestone.

BOURBON.—Souvenir de la Malmaison.

CLIMBING ROSES.—William Allen Richardson (N.), Gloire de Dijon (T.), Bouquet d'Or (N.), Belle Lyonnaise (T.). *Summer-flowering Varieties*.—Blairii (H.C.), Charles Lawson (H.B.), Coupe d'Hébé (H.B.), Bennett's Seedling (Ayr.), Félicité Perpetue (Evergreen), and Madame Plantier (H.N.).—E. M., *Berkhamsted*.

HYBRID PERPETUALS.

Position in Present Analysis.	Average Number of Times Shown in the Four Years.	Number of Times Shown in 1889.	Name.	Date of Introduction.	Raiser's or Introducer's Name.	Colour.
1	36.2	24	Madame Gabriel Luizet	1877	Liabaud	Light silvery pink.
2	33.0	33	Her Majesty	1885	Bennett	Pale rose.
3	32.5	38	La France	1867	Guillot	Silvery rose. B.

THE CULTURE OF ONIONS FOR GENERAL USE AND EXHIBITION.

It is now about thirty years since Banbury and district became famous for the production of fine Onions. The method of cultivation practised by some of the best growers was to select an elevated piece of ground, and in the month of October to trench three spits deep, working in a good dressing of farmyard manure. The bed would then remain until December, when it would receive a top-dressing of soot; this would be forked or raked in, and the ground made firm early in February, and the seed sown at the same time in drills 10 inches apart, and as soon as the plants were established they were thinned to 8 inches apart.

The beds were never allowed to get dry during the growing season, and received liberal top-dressings of well decayed manure sifted, as also artificial manures of various kinds. I would recommend those who grow for general crop to adopt the same plan as given above, with the exception of the distance in drilling, &c., which should be 6 or 7 inches from drill to drill, the seed sown thinly, and all the plants left, none being pulled.

I now come to our modern or present growers, such as Mr. Wingrove, Rousham Park Gardens; Mr. D. Murray, Culzean Castle; Mr. W. Pope, Highclere Castle; Mr. Wiles, Edgcote Park; Mr. Miller, Rood Ashton Park; Mr. Doherty, Wroxton Abbey; Mr. Bowerman, Hackwood Park; and Mr. N. Kneller of Malshanger Park. The first six named gardeners have grown magnificent bulbs, 16, 17, and upwards of 20 lbs. the dozen, the last two named growers producing this year twelve bulbs weighing 29 and 30 lbs. respectively, the varieties being Rousham Park Hero and Ailsa Craig.

The methods are much alike with these growers. In October the ground is deeply trenched with two layers of good cow manure, and in January a heavy top-dressing of soot and lime, which is well forked in during March. The seed is sown in boxes in a cool vinery or frame about the 1st of February, and when about an inch high pricked out 3 inches apart each way into other boxes, and grown in gentle bottom heat with plenty of air until about 6 inches high, then hardened off and planted into the

beds a foot apart each way. When established the beds are mulched with cow or spent Mushroom bed manure and liberal top-dressings of Cannell's, Deverill's, or Thomson's manures applied in showery weather or well watered in.

The ground, of course, to grow fine Onions should be a strong, stiff black or red loam, it being impossible to grow exhibition bulbs on light soils. Frequent heavy waterings between the rows is absolutely necessary to ensure success.—H. DEVERILL.

RESTORING UNSATISFACTORY VINES.

IN accordance with my promise I send a few lines as to the treatment adopted with my Grape Vines, which have previously been in an unsatisfactory condition, but which are now carrying a heavy crop of fruit, the colour fine, and the berries—according to your high opinion—above the average size. I will commence from the time I took charge of them, which was in August, 1886, when I found the Vines in a weak and exhausted condition, the bunches and berries being very small and their colour red. On examining the foliage I found it very flabby, but the worst of all was many of the shoots which should have been quite ripe and brown were still green. I knew the cause of this laid at the roots, and on examining the border (which is outside) this assumption proved to be correct, for they were very deep down in the border and appeared to be dying in consequence. The only course to remedy this evil was to try and raise the roots to the surface. I therefore decided to partly renew the border, which I did in the month of October. I took out all the old soil, beginning from the foot, until the roots were reached, and then supplied fresh cut turfy loam; and as the filling proceeded a good layer of cow dung was added between the courses of loam, and a fair sprinkling of half-inch bones was applied. Of course, as I filled the border again the greatest care was taken to have all the ends of the roots well in the new soil, and their points were directed upwards, so as they grew they would come to the surface. From the other part of the border I had a good spit taken and applied the same composition with the addition of Burrell's artificial manures.

After all was completed some long litter was spread over the border to throw off the heavy rains. This was removed again in the spring, for I am confident that where Vine borders are allowed to be covered in the summer more evil is caused than good.

The inside treatment I adopted was to give a longer period of rest, therefore they were not started until March, and then an abundance of ventilation was provided at the top both night and day. This was to induce them to break strongly for another season's crop, for I did not expect much this season. My aim was to grow them strongly and encourage as much root-action as possible; I therefore let the young shoots run more freely without pinching. The second year I could see the beneficial results of my labours, as they broke more strongly and showed a crop of fruit; but as good Grapes were wanted I decided to give them another year's partial rest, therefore all the larger portion of the bunches were pinched off, and I am quite sure I am repaid tenfold for my pains. I omitted to mention when I took charge of the Grape Vines they were very subject to shanking, but now I have scarcely a shanked berry, and the wood has that beautiful brown and ripe appearance that they seem certain to carry an excellent crop another year.—ALFRED BISHOP, *Westley Hall Gardens, Bury St. Edmunds.*

PELARGONIUMS AND BEGONIAS AS BEDDING PLANTS.

For many years Pelargoniums have been the reigning beauties of the flower garden. Other rivals have tried to displace them, but until now the necessary essentials have been lacking in each one. Verbenas and Calceolarias have failed to rule, although they both possess much beauty, and even the few years that carpet bedding held the sway appear only to have increased our fondness for the old favourite. Pelargoniums possess a greater power of adaptability than most other plants, so that whether in groups or singly they are always pleasing and worthy of admiration. They have received a great share of the hybridiser's attention, until the favourites of our early days are almost forgotten, except when in some old garden we happen to see a forlorn specimen of Tom Thumb, which recalls to our memory the names of some other varieties. Yes, Tom Thumb and Stella have been replaced by Vesuvius and Henry Jacoby, but amongst the multitudinous varieties now extant it is very questionable whether any will be remembered as long as they have been. It need occasion no wonder that Pelargoniums have been so long honoured when we think of their varied forms and colours. The trusses of bloom stand clear out from the dense foliage, as if eager to do its part to brighten the surroundings, and show the artist's work off as much as possible, while the varieties which are cultivated for their foliage—whether bronze, silver, tricolors, or others—perform their parts in the same way. There is a certainty about Pelargoniums which has much to do with their popularity, so that when planted out they are sure in an ordinary season to fill the space allotted to them in the desired manner. Failures with them are of rare occurrence, and although grown in the same beds where their progenitors grew for years before, they have so far escaped any virulent disease. What may be termed their adaptability to circumstances is well known to all, for as soon as planted in the beds the effect intended to be produced is apparent, probably more so than with any other bedder. The effect also improves until the bed is completely filled, and the operation of taking cuttings has to be performed to prevent overcrowding. After the cuttings are removed, and a genial autumn follows, the beds of Pelargoniums are generally the most satisfactory in the flower garden, even if they are more sombre than some of the other occupants. Their dwarf compact habit of growth prevents the storms from committing great ravages amongst them, while no unsightly stakes show themselves obtrusively in their midst. Altogether they are most useful for furnishing the flower garden, and if only double varieties could be raised that would be as floriferous as single sorts, we might never expect to see a more popular plant.

As it is, perfection has not been reached. This changeful climate of ours plays occasionally sad havoc with the petals, and so we continue introducing every plant that gives promise of greater stability and effect. The one which has gained most popularity of late is the Tuberosa Begonia. Steadily and deservedly it has advanced in favour, and even sceptics, if there were any, must have been convinced, after the account rendered of it last year, that a decided acquisition had been secured. I can remember the first plants of B. Chelsoni being brought into the houses of which I had charge, and how at first we coddled them in the stove until they were drawn up and nearly useless, when we tried and found that they liked cooler treatment better. Soon after, when in "Veitch's" for another situation, in the department presided over by that excellent plant

grower the late Mr. May, I learned to like them in something of the same degree that he did, but at that time few could have predicted such a future for their descendants as they have gained. I think he believed they would eventually eclipse Pelargoniums, and at present they bid fair to do so. The yearly improvement of the different strains makes us wonder what will be the next advance, as those now used for bedding are much better for the purpose than formerly.

No better opportunity could have been afforded us for judging how far they are suited for bedding out purposes than the extremes of this season and last year, and it is well that this test has been applied to them thus early in their history, as those who are called enthusiasts are apt to form hasty opinions from favourable appearances. Last year most satisfactory reports appeared from all quarters, and many who had not grown them were tempted to do so, and those who had them before in many instances increased their numbers. It may be safely stated that in no instance has disappointment been the result, although the cases are many in which the effect they produced was beneath the expectations. Two causes are partly to blame for this result. The weather of last year was favourable for their well doing and unfavourable for Pelargoniums, so that the poor appearance of the one heightened the effect of the other. This season the same result was noticeable, but in a manner directly opposite, the Pelargoniums this time being the favoured ones. Nothing could have been better than their glowing colours during the heat of July.

Besides being deficient in decided effect, which even the upright forms cannot altogether remedy, their lateness in blooming is against their being too extensively planted where earliness is desired. They are essentially autumn flowers, and most charming, but it is doubtful if ever the most careful hybridising will produce a strain with stems sufficiently strong to show the colours so effectively as Pelargoniums. Large-flowered varieties should not be employed so much as some advise, as they are more easily damaged than medium-sized varieties. One strong point in their favour is the easiness with which they can be housed during winter, but in gardens where this has not to be studied so much it would be well to give Pelargoniums still the first place in the flower garden, and rank Begonias with Calceolarias and Verbenas.—M. D.

HOW TO PROCURE RIPE GRAPES IN MARCH.

To accomplish this would appear to many almost an impossibility with Vines planted in inside and outside borders; but having been fortunate enough to secure a cultural commendation from the Royal Horticultural Society for some Grapes shown at their meeting on March 26th this year, I thought that a few practical notes on the cultivation here may be of service. Since receiving the above reward I have been asked by a brother gardener for such notes, and I am granting his request by placing them in the Journal, so valuable to many readers.

The Vines, all Black Hamburg, were planted in a lean-to-house fourteen or fifteen years ago, but were, I believe, not forced so early until I took charge of these gardens four years since. The Vines had been up to that period treated as late, the Grapes generally ripening about the end of June. The Vines being in good condition stood the extra forcing well. The house was started by the middle of November, the Grapes were ripe by the third week in April, and were forced a little earlier each season, this year being ripe at the time above stated.

The practice here is at about the end of July to shorten all the lateral growths back to where they were first stopped, following with a further pruning back to four or five eyes at the end of August, which we consider is a great help to the ripening of the wood. The final pruning back to the last two eyes is performed at the end of September; the Vines are then cleaned, great care being taken in doing this, as often through carelessness many young buds in the old rods and at the base of the laterals are rubbed off, though they are often essential to the early forcing of Grapes. As will be shown later on, the Vines are not barked more than can be avoided, as luckily we are not troubled by mealy bug, that detestable pest on Vines, the only insects being red spider and scale. We wash the rods with a strong solution of Gishurst compound, brushing it well into the wood, especially round the base of the laterals. The woodwork of the house is then washed with strong soapy water, the walls being whitewashed with fresh slaked lime.

Attention is next turned to the inside border, clearing all the refuse and loose soil off the surface, and loosening the top with a fork, taking great care not to break any of the roots, as those on the surface are most valuable and ought to be encouraged. We then give the border a good sprinkling of bone dust or half-inch bones,

and Clay's fertiliser with a little lime and soot added. It is covered with a small layer of good stiff loam. All are forked together, and the border is well watered, repeating the application in the course of a few days, so that we can rely on all parts being thoroughly moistened. We recommend this early watering of the border in preference to leaving it until the house is started, as it induces good root-action before the Vines commence growing. The outside borders are then treated in the same way, although if we can secure a heavy rain on it after being prepared in the course of a week or so we consider this preferable. About the end of October we close the house, and at the same time we make a hotbed outside composed of one-half leaves and the other good heating manure fresh from the stable, made to the depth of about 2 feet, covering the whole with old lights or wooden panels made for that purpose. We do not endeavour to obtain any violent heat, the object aimed at being to protect the border from the cold atmosphere, heavy rains, and snow, and to keep the soil as dry as possible through the winter. About a fortnight after closing the house a little fire heat is provided on dull days and nights, the temperature ranging from 60° by day to 55° at night, rising and falling according to the weather outside. Thus, if there is a sharp frost we should expect the house to be below 55°; if the night was warm above 55°, and if the sun was shining over 60°, &c. The endeavour is to keep the fire heat as far as possible to one temperature, and this, I think, is well worth a little consideration, by young men especially, as I believe the more closely we follow Nature the surer we are of success. The house when started should at all times be kept moist by constantly syringing the walls, staging, and borders, and the rods three times a day, for keeping red spider, thrips, &c., in check is greatly assisted by this in the early part of the season.

As soon as the young growths have reached the stage when on close examination the bunches can be detected, those not having any fruit are at once removed, and now will be seen the advantage of careful cleaning. All those buds not injured will be found useful in producing a crop of fruit as well as forming new laterals. We had a good example of this last year, as from the leading buds not more than an average of four to a rod showed fruit, when after removing all those not showing we were in the end able to obtain a good crop, and strange to say, that although some were colouring when others were in flower and just set, they all finished well. This year the wood all seems in good condition, being well ripened, a sample of which I sent herewith pruned a few days ago. This is not a chance practice, but has been carried out here for the last three years with success. Great care is taken when tying down the laterals, going over them often rather than run the risk of losing one, and to aid this we let the rods hang below the wires 2 or 3 inches, and strain them up tighter later on in the season.

We now come to the setting process. The dry temperature, as practised in many places, is not carried out here, the object we aim at being to keep a warm moist atmosphere, with a little ventilation always on when practicable, and the temperature is raised to 65° by night and 70° by day, drawing the hand lightly down the bunches before syringing in the afternoon. As soon as the majority of the bunches are set we give the inside border a good supply of strong sewage water, raised to a higher temperature than that of the house. On no account after the Vines are started let it be colder, and if we can catch a bright sunny day so much the better, that we can well ventilate, and so allow the ammonia, &c., to escape, which would otherwise do injury to the young foliage; this greatly assists in the stoning. The soil close to the pipes should at all times be kept watered, as dry soil helps to breed insects. As soon as they have finished stoning we again raise the temperature 10°, and give another good watering as advised above. This is sufficient until the Grapes are ripe, only supplying clear water after when required. The hotbed is taken off about the end of March.

In thinning great care is taken to remove all the small berries, as they never finish, and only help to disfigure the bunch. Should red spider appear we at once supply sulphur to the roots, which soon prevents it spreading any further. In conclusion, I trust that any imperfections in these notes will be excused, as I am only a young contributor, and already I feel that some of our large growers disagree with a portion of the above practice; still I should be glad to read their opinions.—W. PALMER, *Thames Ditton House*.

[The wood received is firm, well ripened, and capable of bearing good fruit.]

LAVENDER.

THE interesting and instructive article by Mr. L. Castle on Lavender, p. 193, which appeared in this Journal on Sept. 5th, has created a favourable impression here where the land is of a calcareous nature. Although the distance the chalk lies under the surface varies considerably in different parts of the estate, in some places there is only 1 foot of soil, in others the chalk is not reached

at a less distance than 8 feet. Even at the latter depth the soil is highly impregnated with chalk, as this is largely used by farmers for dressing the land in winter, which then falls to powder by the action of the frost. All the land on this estate is heavily mixed with flints, which assist the percolation of the surface water. From the description of the soil required to grow Lavender well we considered that success might be obtained. Mr. Myers, being a thorough enthusiast in any scheme likely to prove beneficial to his estate, has determined to put the matter to a practical test on the lines of culture laid down by Mr. Castle. The position chosen is one facing south, which is already sheltered on the eastern side by a young Larch plantation, and on the north side it is intended to make a similar plantation, and as this tree grows fast when once established in this soil we do not apprehend any difficulty in sheltering the Lavender. I have therefore set about preparing a stock of plants, which I apprehend will be ready to plant permanently out towards the end of April. Not having stock enough to obtain sufficient divisions of old plants we have taken cuttings from 4 to 6 inches long, the base of each being furnished with partly ripened wood, which will emit roots quicker than the soft green shoots nearer the point of growth. The lower leaves are trimmed off neatly, the cuttings are then dibbled thickly in sandy soil in a cold frame, making each thoroughly firm at the base. The frame will be kept shaded for a short time, and little air will be admitted until callusing takes place, and as soon as new growth is discerned abundance of air will be admitted to keep the plants sturdy. Each one will, no doubt, be lifted with a little ball of soil attached, the base of the frame being prepared for this by placing a layer 2 inches thick of decomposed horse manure, into which the roots will run.

As an experiment we have broken into pieces the remaining old plants, slipping off the branches which consist of two and three twigs that have no roots. These are dibbled firmly in the soil on a west border, first placing a small portion of sand at the bottom of the hole to encourage the rooting process. I daresay a larger stock of plants might be raised from seed, but my experience of this mode of production does not warrant the trial, as a few years since, wishing to obtain a stock of plants for garden growth, I obtained a packet of seed. The plants resulting quickly grew to a good size, but they so varied in character, some lanky, some very bushy, while others were spindly, and scarcely any of them flowered like the true *L. vera*, which I afterwards obtained from cuttings. I am afraid the weeding out process might entail the loss of too much time, and I fancy cuttings may give the best results. After a start is once obtained no doubt dividing the plants is the best plan, even if the growth has become somewhat weakened by age. Perhaps Mr. Castle may have something to say on the question of raising plants from seed, and can he give any information on the distillation of the flowers?—E. MOLYNEUX.

THE GOLD MEDAL FRUIT ESSAY.

HONOURS IN HORTICULTURE.

BEING unable to answer all the letters I receive on this subject, I should like to thank my correspondents for their kind expressions, and to state in answer to many inquiries that the above mentioned essay is being prepared for publication in the cheapest form the cost of production will allow. It belongs to the Fruiterers' Company, and their object is not to derive profit by it, but to disseminate information on fruit culture amongst cottagers and small holders of land. The pamphlet cannot be ready for a few weeks because of the time that is necessarily involved in the preparation of engravings from sketches that were introduced for the purpose of elucidation.

The kind words of some of the competitors for the prize are especially appreciated, and it may, perhaps, be well to state that not a line of my handwriting appeared in the essay sent in, and the Judges were not a little astonished when they found to whom they had awarded the prize. I should like to add that I shall not consider it well won if the small work does not prove useful. The medal is the more valued in being a *fac simile* in design of one granted to Dr. Hogg by the Pomological Society of France on the production of the last edition of the "Fruit Manual."

I am fully conscious there are many volumes on horticultural subjects that have been published during recent years far more entitled to distinction than mine can be, but the Royal Horticultural Society bestows most of its medals, and some very worthily, on tradesmen for advertising their goods, though a welcome departure was made this year in the bestowal of a very handsome one to Mr. Barron for services in horticulture; and a gold Knightian medal was on a previous occasion awarded to Dr. Hogg for his classification of Apples. The Veitch Memorial medals are awarded for "exhibits," most of them worthy of their kind no doubt, but all

of them have not been by any means deserving of such a prize. If I am correctly informed, one of these medals has been "won" with plants bought for the purpose, not from Messrs. Veitch, but from another nursery. They were pointed out to me at a show by a person who stated he assisted to pack them for the purchaser.

As it is extremely unlikely that I shall compete again in a literary or any other contest for a prize, I am free to express my opinion that the whole of the honours indicated should not be granted for something staged at a show, but a reasonable proportion should be bestowed on persons who deserve some tangible recognition for long and able services rendered to horticulture, either in private or public gardens, nurseries, societies, or through the agency of the press. Some of the hardest and most indefatigable workers have no opportunities for winning prizes for products at exhibitions, yet they have done far more in expanding the industry of horticulture, creating a taste for gardening, and promoting high culture than have half of the showmen to whom medals are almost exclusively awarded. Surely fitting recipients might be found yearly for at least one each of the honours at the disposal of the Royal Horticultural Society and the Veitch Memorial Trustees for work well done outside the show room or tent. There can be no difficulty in finding men who are deserving of recognition in the form suggested, and exhibitors of produce could still have the share to which they are fairly entitled. I trust the matter will be considered by the authorities.—J. WRIGHT.

STORING GLADIOLUS GANDAVENSIS.

FROM this time forward those who have valuable collections will be seriously considering the lifting and storing. Lemoine's new hybrids are said to be "hardy," and it will presumably be urged they may be left out during the winter months without risk. The few of them I have grown, for convenience in replanting the beds, and for the reason that I maintain the drying and storing is the completion of the ripening process, I have always lifted with the hybrids of *G. gandavensis*. Perhaps you would invite the opinion of some correspondent who has grown and left out during the winter Lemoine's hybrids of *G. purpurea*.

I have frequently, by design and by accident, left corms in the beds; for instance, Claribel and Berthe Roubardin in the same position unstirred for three successive years, and they seemed to degenerate, besides having the tops of the flag-like foliage always turned back in spring. They were too deep in the ground for frost to reach them; I therefore come to the conclusion that except in avoiding the trouble of lifting and storing, nothing is gained by leaving hybrids of *G. gandavensis* over winter in the beds or open ground. I note this, as the point has been frequently urged. None of the large trade growers, from Messrs. Kelway & Son of Somerset, where the winter might be supposed to be comparatively mild, to Mr. Burrell of Cambridge, or thence to Mr. Campbell of Gourock, N.B., think of doing it; and the same is true of Ireland, north and south. For convenience I may refer to the system of storing in connection with the method of growth.

GROWN IN POTS.—I gather from various correspondents that many amateurs, especially in towns, have grown Gladioli in pots this year. They look very effective, raising up from a bank of Ferns or foliage plants in a conservatory, and when so utilised will, as a rule, be withered by this time. There are some late-flowering varieties, such as Duchess of Edinburgh, James McIntosh, Reine Blanche, Asmodeus, &c., that may not have bloomed even yet, though for the first time the first-named has this year bloomed finely for me in September. I have often had them cut down by frost, blooming the first week in December. If pots are plentiful and space no consideration, those that have bloomed and been outside maturing for some time, presumably duly attended to with water, may now be stowed away in any shed or dry place for the winter. They will turn out in capital condition for planting at the beginning of next March. If they should be kept in the least moist growth will commence long before the time for planting or even potting, and Gladioli can, as a rule, be very badly either repotted or transplanted, owing to the extremely brittle roots or rootlets. In nine cases out of ten they will be shaken out and stored in paper bags or boxes if properly matured and dry. If not withered I like to surround them with moist sand, stem and corm, and let them slowly dry out—that is to say, if the pots might be otherwise wanting.

THE SPAWN.—I just digress for a moment to say that at lifting or shaking out some of the young "spawn" at the base will be lost if not looked after, and it is often very desirable in expensive or scarce varieties to use those cormlets in propagation, especially when they are shy in production. For instance, Calliphon, James Kelway, Mr. Thornton, and Samuel Jennings have been certificated and in commerce some years, and owing to producing "spawn" so

sparingly are still selling at from 3s. to 5s. each, instead of the customary 6d. or 1s.; if they could be increased rapidly by "spawn."

GROWN IN BEDS AND BORDERS.—Nothing is gained by leaving the corms outdoors when it is seen they are ripe and matured. On the contrary, varieties that flowered in July or August, having died down early in a mild autumn, I have known to recommence growth in October and November. That growth cannot be utilised, and simply exhausts the corm, leaving only a very doubtful chance of bloom afterwards. Some, especially of the white and purple varieties, such as of the former, Shakespeare, Dumortier, Dido, Mrs. Reynolds Hole; and purples, M. Chaviere, Phidias, Petrarch, and Lord Digby, show a delicate constitution, and if left in cold, wet, and sodden soil will be likely to decay. Admitting that blooming is past, and, as is always possible from this forward, that frost threatens, lift stem, roots, and all, leaving any soil that may be attached; place them thinly against a wall, partition, or improvised arrangement in a dry open shed or house, and if air circulates freely through them so much the better. Those that show shades of green, and that are manifestly not ripe, should have a layer of moist sand placed at the base, and the corms allowed to slowly dry out. The labels, always a difficulty, may remain tied to the stems; and there, if no good reason interposes, they may remain until planting time arrives. I have removed the cream of my collection to a new town garden, and am agreeably surprised to find they have, without exception, all done admirably.—W. J. MURPHY, Clonmel.

THE BEST TIME TO DIG.

IT is the practice of many gardeners, and is often recommended in calendars, to turn up all vacant ground during the autumn to the action of frost and snow. That no ill effects follow in some cases I am prepared to admit, but these are more the exception than the rule. It is on light and gravelly soils that no injury follows, but on heavy or clay soils autumn digging is positively injurious. We do not attempt to turn up any soil until after the end of January, and then only during fine weather, when we have all hands at the work. By this means we secure a greater depth of pulverised soil. When autumn digging is practised a fine surface of about 2 inches is all that is insured, the under soil being wet and cloggy. If anyone doubts it let a piece of ground be turned up in the autumn and another portion at the time I recommend, and it will be plainly seen which turns up the driest. Autumn-dug ground holds the wet in suspension, whilst on undug ground the rain quickly passes away. We clear all ground of spent crops, and also clear off weeds as soon as we can, so as to expose the surface to the atmosphere. Such soils as I have described should also only be dug with steel forks, as by this means the soil is kept well divided. Spades must not be tolerated for digging except on light soils where the soil will not hold together, and these instances are very few. The soil in these gardens is heavy and cold, but by treating in the manner stated we have no difficulty in obtaining a fair depth of pulverised soil in the spring.—A. YOUNG.

BLACK HAMBURGH GRAPES AT DRUMLANRIG.

ACCORDING to some authorities the cultivation of old fashioned high class Black Hamburgh Grapes is almost a lost or unknown art, and there is some truth in their assertions, as the rage for bulk and show has brought many of the coarser varieties of Grapes into prominence. At midsummer and autumn shows, seasons when the Black Hamburgh should be clearing all before it, it is shunned by exhibitors; Alicantes, Gros Colman, Gros Maroc, and even Lady Downe's taking the lead everywhere. In fact, I know instances where the Black Hamburgh was discarded to give place to these more showy varieties, but all who still regard quality as the first point in Grapes have an unlimited affection for the Black Hamburgh with its clean medium-sized superbly flavoured bunches and berries.

Mr. David Thomson of Drumlanrig grows the Black Hamburgh at the present time as well as it was produced at any time; in fact, I am inclined to go further, and say that the crop of this fine Grape I saw at Drumlanrig in the middle of September was never surpassed, and I know all who have witnessed Mr. Thomson's ability as a cultivator will have no hesitation in accepting the estimate I place on them. The division of the house in which they are growing is 60 feet long, 18 feet wide, lean-to, and the rafters are 22 feet in length. The rods are about a yard apart, rather thicker than one's wrist, and they have been fruiting for over a dozen years. I saw the crop before it was cut, as here the Black Hamburgh is the autumn Grape; the bunches were very numerous, some would weigh a little over 5 lbs. each, but the majority, and they were even, would average 4 lbs. The bunches had been thinned to a

nicety, the berries were fully developed, well hammered, jet black, and with a spotless bloom. The wood was brown, but the foliage as green as in July. As I have hinted, we so rarely see this grand old Grape nowadays in the best condition that the instance merits record, and I feel sure if many saw them they would insist on Black Hamburgs being sent to their table until the end of November at least. I should be glad to read an article in the Journal from Mr. Thomson on the Black Hamburg.—A KITCHEN GARDENER.

SATYRIUMS.

IN the culture of these Orchids I pot the tubers in a compost of leaf soil, loam, and silver sand, and when they begin growing I find

the under side of the leaf; it seems almost hopeless to fumigate, and the only remedy that I find of any use is to dip the plants in tobacco water or other insecticide. I have one plant that has not made any top growth for two years, but the pot is full of tubers, or in other words it has made plenty of tubers but no leaves.

I have plants under the name of *Satyrion acuminatum*, *S. aureum*, *S. carneum*, *S. carneum princeps*, *S. corrifolium*, *S. eristomum*, *S. longicolle*, *S. maculatum*, and *S. membranaceum*.—G. W. CUMMINS.

SATYRIUM AURANTIACUM.

WITH regard to the *Satyrion* figured in last week's Journal, I may say that the tubers are either potted or planted out in a cool frame in light soil—peat or leaf mould is preferable—and kept moderately moist until the first leaves appear. After this they require plenty of moisture. They may also be treated like greenhouse Orchids, but such treatment invariably weakens the tubers. During the summer months the plants are kept during hot sunny days half shaded and with plenty of ventilation. After flowering they are more exposed and kept drier until the leaves turn yellow

FIG. 38.—CATTLEYA MISS HARRIS.

it a good plan to add a little live sphagnum to the surface of the soil, and the roots soon take possession of it. They seem to succeed much better in a cold frame than the open air, for in showery weather I have found the water lodge in the crown of the plant and cause the centre to decay. The pots being well drained and the compost light they require plenty of water when growing, and when the leaves begin dying the plants are gradually dried, and when actually at rest they are stored in the cool house away from frost.

Aphides are the worst enemies to the *Satyrion*, and if allowed to remain on they soon spoil the flower spike. The insects attack

in the autumn, when they are quite dry and ultimately stored safe from severe frost in a shed or cold frame until the following spring. Similar treatment is required by the equally pretty and robust species *S. candidum* and *S. odoratissimum*.—G. R.

CATTLEYA MISS HARRIS.

WHEN shown at the Royal Horticultural Society's Orchid Committee meeting on September 17th last, the above named beautiful and interesting hybrid was greatly admired and unanimously awarded a first-class certificate. It was exhibited by Miss Harris

The Grange, Lamberhurst, and was, we understand, raised in the collection of Orchids at that establishment. It is a hybrid between *Cattleya Schilleriana* and *C. Mossiae*, and it is curious to note that though we have several hybrids in the production of which *C. Mossiae* has been employed as one of the parents, that under notice, and another named *C. Whitei*, are the only ones generally known in which *C. Schilleriana* has been concerned. The famed and almost historical *C. exoniensis* was from *C. Mossiae* and *Lælia purpurata*. *C. Manglesi* was from *C. Mossiae* and *C. Loddigesi*, both raised by Mr. Dominy. *C. exoniensis* has also been utilised by Mr. Seden as *C. Fausta* is from that with *C. Loddigesi*, while *C. triophthalma* comes from *C. exoniensis* and *C. superba*.

C. Mossiae is too well known to need description, but *C. Schilleriana* is not so frequently seen, and it may be well to remind readers that it has the habit of *C. Acklandiae*, the flowers being of a peculiarly rich dark hue that has been not inaptly described as "a deep rosy mahogany colour." The tint and markings vary, in some there is a tendency to a distribution of the colour in spots, and the lip is usually beautifully shaded or streaked with a pink margin. It is a Brazilian species flowering in the summer, when the flowers often last on the plant for a month.

In the hybrid *Cattleya Miss Harris* (fig. 38) the chief characteristics of the last named species have been closely reproduced as regards the form of the flowers, but the colouring seems to have been mainly derived from *C. Mossiae*. The sepals and petals are of a soft clear light rosy crimson hue, the lip being an uncommonly deep shade of crimson. It will take its place amongst the best of the *Cattleya* hybrids, and appears to be of good habit and free growth.—L. C.

HARDY PLANTS.

BEDDING VIOLAS.—The summer of 1889 has been most favourable to the free development and flowering of these useful bedding plants, consequently abundance of clean healthy cuttings were obtainable at the right moment, with the result that we have now plenty of healthy plants. It is perhaps not generally known that to get the best possible results from bedding Violas in early spring we must plant in the earliest days of autumn. For obvious reasons, however, the beds or borders destined to accommodate them are not at liberty much before the end of September in the majority of private gardens, and therefore it is impossible to give the Violas the requisite attention before the early days of October, and this of all months in the year, and particularly in those cases where masses of flower are required early in spring, is by far the best. It is just at this time when everything of a tender nature has been placed within doors, and the remnants of summer bedding plants cleared away, that attention must be directed to Tulips, Hyacinths, and the various other bulbous plants which make our gardens gay in spring time, and where such bulbous plants as these exist we have nothing which can equal the bright charming masses of flowers which Violas produce to adorn the surface of the beds, or in other words to serve as a carpet. Beds destined for the reception of Hyacinths and such bulbs will, of course, be well and properly prepared by digging, manuring, and so forth, and therefore specially adapted for Violas, so there will be no need for comment in this direction. As regards planting, a little forethought will prevent the Hyacinths occurring immediately below the Violas. This may be easily regulated by planting at certain distances apart, or if the bulbs are planted with a blunt dibber the marks of the latter may remain on the surface till the Violas are planted, and thereby insure both being in their proper places.

Another item which should receive attention at this time is that of matching the colours in these two groups—i.e., Hyacinths and Violas, avoiding too blues or violets or whites on the same bed, as such will mar the general effect in spring. Where, however, it is intended to employ Violas alone—and these are capable of producing a wonderful array of colour in themselves, and at a very nominal cost—liberal treatment should be adopted. In cases where light sandy soils exist nothing can equal an abundant supply of cow manure direct from the sheds, the moisture it then contains is very helpful in keeping such soils cool, and in such all Violas delight, but with soils of mere retentive nature light manure and leaf soil mixed will be more suitable, working in plenty of sharp grit or burnt ashes from the rubbish fire, all of which will assist in making the soil more readily worked, and the beds prepared no time should be lost in planting. A selection of good varieties are Countess of Hopetown, Jeffrayanum, Pilrig Park, Champion, all whites; Bullion, the best gold; Ardwell Gem, the best canary; True Blue is excellent, very dwarf and free; Archie Grant, a bold violet purple; Mrs. Charles Turner, rich plum; Duchess of Albany, white or mauve; and Elegans, lavender. Any or all of these are very effective in masses, and to which we can

only add the indispensable shades of purple crimson found in Cliveden Purple and Crimson Gem.

HEPATICAS.—These, if a full measure of success be coveted, should be divided and replanted at once. The generally adopted method is that of dividing and replanting in early spring as soon as flowering is completed. It is, however, not a safe plan, although it may be adopted with a fair amount of success provided a showery season follows the operation, and it is here that the risk is run, for too often in spring time when the operation should be carried out we are experiencing dry harsh winds not the least likely to be of service. At the same moment, as it were, the new foliage springs forth, and for these and other reasons these plants are much better divided and replanted in the early autumn months, as they root without any check from the weather, and are sure to develop good flowering crowns for another year, which latter does not always ensue when the operation is performed in spring. Where large old established clumps exist it is best to divide into several pieces and make a small group rather than to allow it to remain in one clump, a greater mass of flower would result twelve months hence by adopting this course. Hepaticas always make a great quantity of fibrous roots, which quickly impoverish the soil, so that in replanting a plentiful supply of manure should be given, also decayed leaf soil and a bushel or so of old mortar rubbish if obtainable will also be welcomed by the plants. Deep digging, too, is of the utmost importance. A partially shaded and somewhat cool, though not sunless spot, suits them well, though I may remark that a quantity of *H. angulosa* is doing well without the slightest shade whatever. This is the most lovely of all, and generally retains its foliage throughout the year, which cannot be said of the forms of *triloba* when exposed to much sun; particularly is this the case when under the influence of a smoky atmosphere. The Double Blue is the most fastidious, and seems to require a moister soil than any other variety.—J. H. E.

WATERCRESS.

I HAVE no doubt that the fresh Cress and other green vegetables which are sold in the streets of our large cities have a considerable and very beneficial effect upon the physical condition of the people. Watercress contains much chloride of sodium, iodide of sulphur also; and if we are to believe all that is told us it is not only pleasant to the taste, but contains very valuable medicinal properties. When it began first to be eaten nobody can say, it was so very long ago. It is cultivated in great quantities in England now, and a few weeks ago I visited what may be called a Watercress farm. Passengers by the London and North-Western Railway from Euston to the north must often have noticed the clean, white-looking baskets filled with fresh green Cress, addressed to Liverpool, Manchester, Oldham, Birmingham, and many other places, and have perhaps wondered, as I did, where it all came from. Watercress is one of the things that bring my childhood back. It grew plentifully on the banks of a clear stream that ran musically through a lovely Kentish meadow at the back of the old home, and many a time have I watched while old companions gathered bunches of the succulent plant. It may have been this memory of early days, as much as the taste of riper years, which induced me to go and see the Watercress growing once again, this time in its cultivated state.

"Watercress, ma'am?" said a railway official. "Why we send tons of it away beautifully fresh every evening. There is often a truckload of it coupled on to an express train for the north, and it arrives at the large markets at Liverpool and Manchester by the early morning in first rate condition, and all ready for sale. If you are interested you had better call at Berkhamstead as you go down, or Watford, or any of those places in Hertfordshire, for it is in that county that the best Watercress is grown on account of the fine springs that are there." Berkhamstead has, indeed, an interest of its own. It was there that William the Norman received the submission of Stigand, the Archbishop of Canterbury; and there that the Abbot of St. Albans stopped the progress of the Conqueror by felling the trees and blocking the road with them, and wresting from William an oath that he would govern the town according to the laws of Edward the Confessor. It is a quiet place now, and very quaint and interesting. The Watercress grows plentifully along the bottom of a valley, and looks beautifully green and clean.

The bed is emptied and cleansed once or twice a year—"washed as if it were a room," we are told—and then refilled with the Cress, which is not sown, but is planted as Strawberry plants are. There is no earth, but a little sand and water, and great care is taken not to let any weeds go in with the Cress. There are planks thrown across the Cress meadows so that the men may be able to reach it without trampling the plants down, though in some places they were standing in water, and so getting in the harvest. They cut the Cress with a sharp knife, and put it in large tins, in which it is well washed and carefully looked over, after which it is packed in baskets and sent off. "Do you grow it all the winter?" "Oh, yes, all the year round; but we have some warm springs which keep it all right during the frosty weather. Our Cress may always be bought, for we so manage the different crops that one follows another." They complained in Berkhamstead that it is difficult to buy a bunch of Cress, for though it grew in the place it was not grown for the in-

habitants, but to be sent away to the wholesale markets of the large towns. The same complaint is made in fruit-growing places. "There is plenty of it, but we cannot get any." Is not that a little too bad, since Watercress and fruit are good for the people everywhere?"—**MARIANNE FARNINGHAM.**—(*Christian World*.)

EVENTS OF THE WEEK.—To-day (Thursday) the Hardy Fruit Show will be opened at the Crystal Palace, Sydenham, and a meeting of the British Fruit Growers' Association will be held at 3 P.M., when Mr. T. Francis Rivers and Mr. J. Wright will read papers, several others also being promised upon interesting subjects. On Monday, October 14th, the National Chrysanthemum Society's General Committee will meet at Anderton's Hotel, Fleet Street. The usual sales will be held during the week by Messrs. Protheroe & Morris and Stevens at the Cheapside and King Street rooms respectively.

— At a general meeting of the **ROYAL HORTICULTURAL SOCIETY**, held on October 8th, in the Drill Hall, London Scottish R.V., James Street, S.W., T. Francis Rivers, Esq., in the chair, the following candidates were elected Fellows—viz., Wm. Allingham, Walter Joseph Baker, G. W. Lonsdale Barraclough, Mrs. Berry, S. Benshie, Henry Bohn, Henry Briscoe-Ironside, J. G. Clabburn, Lady Cunliffe, Philip H. Davis, W. J. Deighton, Charles Foster, Alfred Gorton, H. A. Grindrod, George Halse, N. G. Hill, Hon. Mrs. Egerton Holmes, James Hunter, J. Kennerley Jackson, Edward Egerton Leigh, Miss Lonsdale, Mrs. Lovett, John Mantell, W. E. Martin, J. McMeekin, W. S. Nicholes, W. J. Nutting, Alfred S. Read, Frank Smith, W. Smith, Mrs. Turner, Captain W. H. Tylden-Pattenson, Charles Warner, jun., James Salter Whiter, Mrs. Wright, Edwin G. Wrigley.

— **NATIONAL AURICULA AND PRIMULA SOCIETY, AND NATIONAL CARNATION AND PICOTEE SOCIETY (SOUTHERN SECTION).**—Mr. J. Douglas writes:—"The annual general meeting of above Societies will be held in the room of the Horticultural Club, Hotel Windsor, Victoria Street, on Tuesday, October 22nd, 1889, at 4 A.M., by kind permission of the members. The business of the meeting will be the election of Officers and Committee; receiving the Secretary's and Treasurer's reports; the election of Judges for the ensuing year; and other necessary business that may pertain to the annual general meeting. The annual meeting offers a good opportunity for the election of new members. We have lost a few during the past year from various causes, and members of either Society would oblige by proposing any of their friends who contemplate becoming members at that time rather than later in the season."

— **ORCHID NOMENCLATURE COMMITTEE.**—It is proposed that the first meeting be held in the Lindley Library, Royal Horticultural Society, 117, Victoria Street, on Tuesday, October 29th, at 2 P.M. Gentlemen having suggestions to make for the consideration of the Committee, are requested to communicate with Dr. Masters, at the above address.

— **RAINFALL IN SUSSEX.**—The total rainfall at Cuckfield, Sussex, for September was 1.23 inch, being 2.11 inches under the average. The heaviest fall was 0.77 inch on the 24th, rain falling on only seven days. The highest temperature (not strictly shade) was 86° on the 12th, the lowest 32° on the 26th. Mean day temperature 70.2°, mean night ditto 46.1°, mean temperature 58.1, being 0.1 under the average.—**R. INGLIS.**

— **CHANGE OF ADDRESS.**—We are desired to state that the Sphinter Grip Armoured Hose Company, Limited, have removed their offices from No. 63, Fore Street, to No. 9, Moorfields, London, E.C., (adjoining Moorgate Street railway station). We are also advised that the above Company's Patent Hose has been shown at the Paris Exhibition and awarded a bronze medal, a higher distinction than that secured by any other hose entered as an exhibit.

— **OCTOBER ROSES.**—Messrs. J. Jefferies & Son, Royal Nurseries, Cirencester, write:—"We have pleasure in sending you a few Roses. We think for October these are fairly good." They are excellent, and the following are the varieties: Ulrich Brunner, Mrs. John Laing, Henrich Schultheis, Madame Berard, A. K. Williams, Earl of Pembroke,

Marie Verdier, Captain Christy, Marie Baumann, Marie Van Houtte, Black Prince, Charles Lamb, La Frauce, and Alfred Colomb.

— **WASPS.**—I predicted last autumn that the wasps would be numerous this year, and so it has turned out. Similar fine weather occurred this year at the beginning of September as it did in autumn of 1888, which favoured the successful mating of the female wasps, and which will in all likelihood result in a plague of them next summer and autumn. Piles of timber are the best traps now; these near woods only need to be turned over during winter and secure those wasps.—**A. L. B. K.**

— **THE opening meeting of the CARDIFF GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION** was successfully inaugurated on Tuesday, 1st October, by Mr. Pettigrew, who read an excellent and instructive paper entitled "The Vegetable Garden." There was a good gathering of members, amongst whom, as visitors, were Mr. Thomson of Ireland and Thomson of Edinburgh, and Mr. Lewis of Manchester, both gentlemen taking a lively part in the discussion that followed the reading of the paper.

— **HYDRANTS FOR WASHING BUILDINGS.**—On several occasions our public buildings have been cleansed externally by steam fire engines, the force of water ejected from these machines effectually washing off the soot and dirt in a few hours. Owing to the increased pressure of water in many of the London water mains, however, this kind of work can also be done by hydrants and hosepipes. The latter experiment has been tried with success at the Royal Exchange, where a Merryweather hydrant with the necessary adjuncts has been permanently erected. The apparatus is easily worked by one man, and as soon as a cleansing is required, the apparatus is at once put in action.

— **YUCCA ALOIFOLIA VARIEGATA.**—A correspondent who has flowered the *Yucca aloifolia variegata* inquires if anyone else has had it in flower. A plant has flowered at Cyfarthfa Castle, South Wales, this summer. The plant in question was about 9 feet high, and as rather more than half of the stem was without leaves I decided on having it "ringed" last January. It rooted freely into a 7-inch pot. When it was severed from the stem I am unable to say, as I left that place in March. My foreman, however, who corresponds with some of the young men at Cyfarthfa tells me that the plant has flowered this summer, and was much admired. The ringing ordeal may have had something to do with its flowering.—**J. JEFFREY, Caversham Park.**

— **IN the Journal of Horticulture** of October 3rd Mr. Wright, in his interesting and valuable article on "THE FOOD OF VEGETABLES," mentions Mr. Divers curing a Peach tree of yellows with iron sulphate. I should esteem it a favour if the details could be given in the Journal as early as convenient. I have one or two excellent Peach trees that are not in a satisfactory condition. I intend partly lifting in a week or ten days. I should also be pleased if Mr. Divers or any other reader would give me information respecting the fruitfulness and hardiness of the two following Peaches, Lord Palmerston and Reine des Vergers. Would they make companions for *Violette Hâtive*, *Late Admirable*, and *Walburton Admirable*?—**T. WELCH.**

— **AS you very kindly published a note on a house of TOMATOES HAM GREEN FAVOURITE** we had growing here at that time (see Journal, August 8th), I thought perhaps you may be interested to know that the twenty-five plants have produced 383 lbs. of fruit. The plants were grown on a slate stage, the soil being 2 feet 8 inches wide, and 6 inches deep. They were grown as single cordons. They were bearing freely when they were taken out; but I was compelled to have them removed as I wanted the house for other plants. I have simply sent you this as most of my gardening friends consider it an extraordinary crop grown under the above conditions. I see the variety has obtained two certificates at the Vegetable Conference.—**E. F. CROCKER.**

— **DOUBLE PRIMULAS.**—Herewith I send a sample of double Primulas with names attached. Are there any better varieties? Cut flowers being largely demanded we make these a sheet-anchor for winter and early spring. We have at the present time some 540 plants, including some of the old Double White, which is not to be despised. Whether the Lady and Marchioness be distinct or not I cannot say, for sometimes one takes the character of the other. Be that as it may, both are good. Compared to these the singles are not "in it."—**H. SHAW, The Gardens, Oakworth House, Keighley.** [We have never seen better examples of culture, and the Lady is the best double white Primula that has come under our notice. Good plants are worth exhibiting before the Royal Horticultural Society, the last-named variety for a certificate.]

— WE regret to have to record the death of two gardeners well known in the neighbourhood of London—namely, MR. W. HALL, of Tulse Hill, and MR. FRASER, formerly gardener to Mr. Measures at Streatham, and lately in charge of Mr. White's collection of Orchids at Arddarroek House, Gourock, N.B. Mr. Hall was on a visit to Arddarroek on Saturday, September 28th, and went upon the yacht Osprey with Mr. Fraser, when a steamer leaving Kilmun for Gourock at eight o'clock came into collision with the yacht, causing it to sink instantly, Mr. Hall and Mr. Fraser, with another man, being drowned. Mr. Hall has been a successful exhibitor of Chrysanthemums, and has for many years been the esteemed Hon. Secretary of the Brixton Chrysanthemum Society, but of late years he has been chiefly engaged in the culture of Orchids.

— MR. J. MALLENDER sends the following SUMMARY OF METEOROLOGICAL OBSERVATIONS AT HODSOCK PRIORY, WORKSOP, NOTTS., SEPTEMBER, 1889:—Mean temperature of month, 57.4°. Maximum on the 11th, 73.3°; minimum on the 18th, 31.5°. Max. in sun on the 6th, 125.5°; min. on the grass on the 23rd, 24.0°. Mean temperature of air at 9 A.M., 55.4°; mean temperature of soil 1 foot deep, 56.7°. Number of nights below 32°, in shade one, on grass six. Total duration of sunshine in month, 102 hours, or 27 per cent. of possible duration. We had four sunless days. Total rainfall, 1.43 inch. Rain fell on fifteen days. Average velocity of wind, 7.9 miles per hour. Velocity exceeded 400 miles on two days, and fell short of 100 miles on four days. Approximate averages for September:—Mean temperature, 55.8°; rainfall, 2.51 inches; sunshine, 107 hours. A dry month except for one heavy fall; other conditions about the average.

— GOOD THINGS FOR THE GARDEN.—Being strongly of the opinion that good things cannot be too widely known, I am sure you will pardon my anxiety to bring before the notice of the readers of your Journal the excellent qualities of Sutton's Little Gem Cabbage, which, if sown in April, will be fit to eat by the end of August or early in September. It is the earliest and most delicate flavoured Cabbage I know, and as a gardening friend of mine said the other day, you can suck it through a quill when cooked. Being small, as the name denotes, it can be planted 1 foot apart each way, thus giving as much produce from a given space as though planted with a larger kind, but with this great advantage, that the one is fit for a nobleman's table, whilst the other is more useful for pigs. It is equally good for autumn sowing, and should be grown by all in search of a gem for the garden.—J. HUGHES, *Edgbaston, Birmingham*.

— I SEND you samples of the CARNATIONS from plants struck last year, and which have given us quantities of blooms for at least three months. The one named Miss A. Porter was among others secured in a purchase of unbloomed seedlings from Mr. Turner, Slough, by Mr. Porter of Kingsclere, which has established itself a general favourite. I should be glad of your opinion of it, and the description of its colour. Miss Porter's name was given it by their gardener, Mr. Norris, it being her especial favourite. The blooms sent are less than half the size of the first blooms that expand. It is of free habit, and an abundant bloomer.—W. STRUGNELL. [The blooms received are excellent—large, bright, and pure in colour. Miss A. Porter is a capital variety of a deep salmon-pink colour, very clear and good. Gipsy is dark maroon; Colonel Cox a rich scarlet; and Mrs. Oldacre a soft, rosy tint, with a purplish hue. All are good.]

— FRUIT TREES AND CATERPILLARS.—The season is now at hand when we are reminded to take precautions to prevent the ravages of the looper caterpillar tribe, but in too many cases I fear the remedies used were failures. They certainly were in our case, applied at the latter end of October, 1888. The proposed remedies we tried were bands of sacking and Hessian smeared with grease, tar, and carbolic acid, with the result that the caterpillars were as numerous as ever. One thing seems peculiar about the present season, and that is, that fruit such as Apples and Pears is more abundant, and the trees much healthier, in close proximity to large towns. I noticed it first in and near Reading. One lady remarked that they had more fruit than they had for years past. Of course more fruit meant less caterpillars, and on the occasion of the recent Vegetable Conference I noticed the same in the R.H.S. Gardens at Chiswick. The leaves on the Pear and Apple trees showed no sign of the ravages of the caterpillars, and there was a fair crop of fruit; and I noticed the same whole-leaved and healthy appearance in Pear and Apple trees at Brentford and Isleworth. Now, the question is, What was the cause of the immunity of these suburban districts from the attacks of caterpillars, and consequently in many cases a fair crop of fruit?—R. MAHER, *Tatten den Court, Newbury*.

— WE regret to announce the death, at Manila, on July 28th last, of SENOR DON SEBASTIAN VIDAL, Inspector-General of the Philippine Island Forests and Director of the Manila Botanic Garden. He held the post for a considerable period, and was the author of numerous important works on Philippine botany. He paid two visits to this country in his official capacity; a first of two months' duration in the autumn of 1877, and a second of four months' in 1883-84. Both periods were spent at Kew in working up the Philippine flora; and he deposited in the Herbarium a set of no less than 4062 specimens for future reference. His published works are:—"Catalogo metódico de la Plantas Lenosas observadas en la Provincia de Manila," 1880; "Resena de la Flora del Archipiélago Filipino," 1883; "Sinopsis de Familias y Generos de Plantas Lenosas de Filipinas," 1883, with an atlas of 100 folio lithographed plates; "Phanerogamæ Cumingianæ Philippinarum," 1885; and "Revision de Plantas Vasculares Filipinas," 1886. The two latter were the result of his last visit to Kew, and he was assisted in their preparation by Mr. R. A. Rolfe of that establishment. Senor Vidal was the first to investigate the Philippine flora since the time of Blanco (when geographical botany as a science was practically non-existent), and we owe to him, not merely a widely extended knowledge of its constitution, but also the establishment of the fact that the Philippine flora, though substantially Malayan in character, yet presents a number of very important peculiarities.—(*Nature*, October 3rd.)

— THE WEATHER IN SEPTEMBER.—From September the 3rd to the 19th the weather was fine and bright, and good harvest weather. The remainder of the month was changeable, but mostly dull and wet. The frost on the 18th was the first severe one of the season, and injured many of the tender plants but did not kill any of them. Harvest finished in this neighbourhood on September 21st. The wind was northward twenty-one days during the month. Rain fell on twelve days, the greatest daily fall being 1.09 inch on the 23rd, and the total rainfall for the month being 2.28 inches. The barometer was very variable, the highest reading 30.49° on 16th at 9 A.M.; the lowest, 29.55° on 24th at noon. The temperature varied much during the month; the highest in the shade was 79° on the 11th, and the lowest 31° on the 8th; the lowest on the grass 27° on the 18th. A garden spring was running twenty gallons per minute on the 30th. Dahlias, Heliotrope, and other tender plants were in full flower on September 30th.—W. H. DIVERS, *Ketton Hall, Stamford*.

— DISEASED PEAS.—I have not noticed any response to Mr. Pownall's appeal for information as to Peas becoming diseased (see page 195, September 5th), but probably the following may assist him. When I first took charge of these gardens the Peas were affected in the manner described by him, and were of no use whatever. I attributed it to heavy dressings of leaf soil, and this not of a good description, as it had laid in heaps closely together in pits in the vineries. The old refuse heaps described by Mr. Pownall would be something similar. After discontinuing it in the kitchen garden the disease disappeared. I think it is much the best system to burn or "smother" all vegetable refuse, as in this state it is better for the crops. The present has been a wonderful Pea season with us, and indeed for all other kitchen garden crops. A dressing of lime I should say would certainly benefit the Pea ground, as well as a dressing of very fine bone-flour forked in previous to sowing the seed. We apply manure rather heavily for Brussels Sprouts, summer and autumn Cauliflowers, and the following season Peas follow without manuring.—A. YOUNG, *Abberley*.

— BIRMINGHAM GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.—The first meeting of the autumn session of this Society was held on Tuesday evening, October 1st. The President, Sir Thomas Martineau, occupied the chair. A large number of members were present, including Professor Hillhouse, the Rev. J. A. Williams, Mr. Latham, Councillor E. Butler, Wednesbury, &c. The President spoke of the very great pleasure it gave him to be present on that occasion, and congratulated the members upon the very great progress that had been made during the year. Particularly gratifying was it to note that many valuable books had been added to the library, which was freely used by the members, the average attendance during the year being ninety, which he considered most satisfactory. Altogether he felt that he had every reason to be proud of the little cutting he had assisted to put in during the time of his Mayoralty, little more than three years ago, seeing how quickly it had made roots, thrown out its branches, and thoroughly established itself among the educational institution of the city. The President then briefly introduced Mr. J. Wright, who attended by invitation to read his paper on "The Social, Intellectual, and Professional Position of Gardeners." The paper was pregnant

with good advice to gardeners, old and young, and met with general approbation, evidence of which was to be found in the frequent applause of the members. Professor Hillhouse, after a powerful and congratulatory speech, moved a hearty vote of thanks to Mr. Wright for his paper. This was readily supported by the Rev. J. A. Williams, Mr. Latham, and Mr. Jones, and was unanimously endorsed by every member present. Several new members were elected. A magnificent collection of Tea Roses and Cactus Dahlias was exhibited by the Rev. J. A. Williams of Alderminster.—J. H., *Birmingham*.

CORNUS SPATHI.

SEVERAL beautiful variegated Dogwoods are in cultivation, and the varieties of *Cornus mascula* in particular are favourites in many

it by the Floral Committee. A small branch of the plant is represented in fig. 39, which fairly shows the depth and proportion of variegation, with the size and form of the leaves, but it cannot, of course, convey an idea of the colouring that renders the variety so pleasing. The leaves are 3 inches long by 1½ inch wide, the outer broad but irregular margin being of a rich orange tint, the centre a bright clear green, forming a striking contrast.

The plant is apparently of Continental origin, but will, no doubt, soon find its way into British trade lists of hardy shrubs. It has not yet flowered, and we cannot be certain if it should be called *sanguinea Spathi* or *stolonifera Spathi*. It is, however, a very hardy plant and a good grower. It also keeps its colour well and does not burn.

It has been distributed by L. Spath, nurseryman, Rixdorf, Berlin. However, that is where Messrs. Veitch & Sons first found it, hence its name

FIG. 39.—CORNUS SPATHI

gardens as standards. The silver and gold variegated forms are the best, and when the foliage is well coloured they add materially to the attractions of shrubberies, the tints being clear and bright. A variety of this species that was sent out a few years ago under the name of *aurea elegantissima* has richly coloured leaves and is free in growth. In nurserymen's catalogues *Cornus marginata aurea* and *C. sanguinea variegata* are named, together with a variegated form of *C. sibirica*, which has obtained some notice by reason of its leaves being broader than many other Dogwoods. At the Royal Horticultural Society's meeting on July 23rd of this year, however, Messrs. J. Veitch & Sons of Chelsea exhibited what was then considered to be a variety of *C. sibirica* under the name of *Spathi*, and a first-class certificate was awarded for

CANKER IN FRUIT TREES.

HAVING taken a little interest in the discussion on the cause of canker in fruit trees, and noted the difference of opinion thereon, perhaps my own views may be admissible. Like Mr. J. Wright, in his excellent article at page 237, I have observed the wonderful effects of winter manuring and irrigation with sewage on fruit and other trees. In one year I have seen restored to health and vigour stunted and cankered, and apparently dying trees of an extensive orchard. I have experienced the remarkable difference of the fruits of one variety of both Apples and Pears coming from one nursery, so that in half a dozen specimens each might have been taken for a distinct variety, the cause being the different stocks the varieties were grafted upon. Two instances under my cultivation at present will suffice to illustrate the

point at issue, a Pear and a Mayduke Cherry. Both are cankered; the former is recovering, while the latter, except one leader, is nearly dead. This tree was formerly a fan-trained specimen, but owing to the stealing propensities of the mining population, has been allowed to grow as it will. The stock of the Pear has not the vigour the graft has, and is much less in size. The graft has for some time past been making an effort to establish itself on its own roots, the wood and bark swelling towards the ground, which it has now reached, and I suppose, although no roots are as yet formed, the bark absorbs the sap, the only way I can account for the canker wounds healing. The Cherry tree has been making a stronger effort than the Pear in the same direction, and one of the leaders has established itself on its own roots, which is the only healthy part of the tree. My theory is that, like the infusion of blood from one person or animal to another, success will only be certain when the corpuscles are of the proper size. So with trees, if the vessels of the stock whereby the sap ascends are smaller than those of the graft, sufficient nourishment cannot ascend to keep the tree healthy.—A. L. B. K.

SEASONABLE HINTS ON FLORISTS' FLOWERS.

WHATEVER may have been its effects on agricultural produce, there can be little doubt that the cool and showery weather of August, which so much retarded the operations of the farmer, was highly beneficial to our gardens, and more especially to florists' flowers, while the bright weather of September has also been beneficial in ripening the wood of other things. Roses have largely benefited by it in ripening the wood, and as a consequence I believe most growers of these plants are congratulating themselves on the appearance of their favourite flowers. In giving them directions as to the management, I would again remind my readers that I write, not from the exhibitor's point of view, but from the amateur's, who likes to grow his plants as if he were going to exhibit, but is not troubled by many of the perplexities which worry him who grows for competition.

AURICULAS.—I have never had so few autumnal blooms as this season. There are some kinds, such as *Acme*, which are proverbially prone to do this, but even they have done so very little this year, while the plants in general have that stout and stocky appearance which fills the grower with hopes of a good blooming time next year. It will now be necessary to prepare to place the plants in their winter quarters—*i.e.*, to remove them from their present position facing north to one facing south. Before doing so it will be desirable to go through the collection carefully, examining each pot, stirring the surface of the soil, removing all dead leaves and weeds, brushing off any aphides that may appear on the plants, and carefully removing any woolly aphides from around the collar of the plant. Whether the creature is injurious or not may be a moot point, but it certainly can do no good, and therefore wherever it is detected it should be removed. They will not require much watering now for some months, but at the same time they must not be allowed to get dust dry, and above all things it must be seen that the frames are drip proof. Nothing is so injurious to the Auricula as a drip; even if it does not go into the heart of the plant, and so occasion decay, yet if it falls on the surface of the soil gradually rendering it soddened and sour, the plant gets sickly, and ultimately dies, and, for the same reason, the dislike of the Auricula to damp, it is desirable to give air whenever the weather is at all fine. Where the frames have to move on hinges it will be necessary to be very careful when air is given, for as the angle of fall is then not so sharp there may be a possibility of the water (should it rain) running back through the laps of the glass. At the same time it must be remembered that although not susceptible to frost so far that it will not kill the plants, yet it is very apt to crumple and spoil the bloom, even when it is enshrouded in the heart of the plant; therefore, should early frosts occur, it will be well to be provided with frigidomo or some other material to place on the frames in frosty weather; in a word, be careful, but do not coddle.

CARNATIONS AND PICOTÉES.—Here again one sees the favourable effects of the season. The plants rooted well, and there was but little necessity for artificial watering; the rain came down so plentifully and at such good times that one seldom had to use the watering can. As far as my own small collection is concerned I never had finer layers, with that beautiful bluish green foliage which so delights the heart of the grower. I have just potted mine, and have placed the layers a few in each pot (48's), so that when I pot them in the spring there will be little disturbance, as they merely want separating a little, and the roots need not be at all broken. The compost should be nearly all loam; a little leaf mould and sand or road grit may be added, and when the plants are done they should be placed in a close frame, shaded from the sun for a few days, and then the light may be taken off and plenty of air given, until they, like the Auriculas, are placed in a warm position for the winter. Care must also be taken with them that they do not suffer from damp; this is apt to bring spot on the leaves, which not only disfigures the plant, but is injurious to its health. If there are any dead leaves they should be removed, and the plant kept scrupulously clean.

PANSIES.—Where these are grown in pots it will now be necessary to have the collection safely housed in small pots. I generally adopt the lazy plan of planting out the old roots, and at this season take them up, clear away all the old and long shoots, and then retain a stout and stocky plant. These I place two in a pot, the same as I do with Carnations and Picotées, and then they are very little disturbed when I have to pot them in the spring. I do not venture to grow Pansies in beds,

for in these southern counties it is vanity and vexation of spirit between the loss from drought and the destruction of the blooms by slugs, earwigs, &c., and so I confine myself to Fancy Pansies grown in pots.

GLADIOLUS.—It has been a capital time for these, and how useful and long continued in blooming they are. I began to cut about July 20th, and to-day, October 3rd, have sent in quite a sheaf of really good flowers for a sale of work, &c. It will be desirable now to take up sticks which have been used to support them, and where they have made holes in the ground to close them up so as to prevent water laying at the roots. I find the foliage of my plants assuming a yellowish autumnal hue, which augurs favourably for their ripening, and should we only have a dry October I expect the roots will lift well. I have had fewer casualties than usual amongst the corms, and am very hopeful of a good harvest. Nothing can be done to the beds until the time for lifting comes at the end of November.

ROSES.—This will be a busy month with Rose growers, and before the time for planting comes and alterations have to be made, it may be as well to go through them, cut out the wood that would have to be cut out in the spring, shorten any very long shoots, so as only to have the pruning to do in the spring, when many things press on our notice and demand our care and time. Where there is fear of frost it may be as well to be provided with bracken or such like foliage to place between the branches, but where dwarfs are grown this is a matter of comparatively little moment, especially if they are well protected about the roots.

TULIPS AND RANUNCULUS.—These may be looked over on some wet day to see that they are all right and free from mildew. Tulips and Turban Ranunculuses may be planted, but at present nothing can be done with them.—D., *Deal*.

PEAS—THE SELECTION OF THE FITTEST.

WHILE staying on the Norfolk coast late in last month (September) I often looked with interest at the little carts of vegetables which came into the town once or twice a week, and on one occasion a woman showed me some Peas. The pods were fresh and full, the peas very large, about ten in each pod. I bought some, by the half-peck. "That's Cater's Telephone," said the woman. "Oh, I know the name well," I replied; "Carter of Holborn, London." "Yes, that's he; my husband and I saw it advertised and we sent for some, and we were sore when the packet came down, that little as yer could hold in the holler of yer hand; but he sowed them and sowed them for three years (they cost us 3s. 6d.); and saved them, and then we begun to sell. And they are beautiful; and they come always like that, and they are just as good till the frost comes. And we have a good profit out of them, and sell a lot cheaper than you can buy them in the shops." That was true; the Peas cooked to perfection, vivid green, soft, of delicious flavour, and I think no better Peas could well have been eaten than those sold to me in the street at Cromer, the variety Telephone, raised by a trustful, persevering cottager and her husband.—A. M. B.

TREATMENT OF SOILS AND MANURES.

MR. BISHOP'S quotation from Johnston and Cameron confirms my statement that "the compound commonly called carbonic acid is carbonic dioxide CO₂." The same authority, as quoted, states that "real carbonic acid 'would have' the composition H₂CO₃," not "has" that composition, for such carbonic acid has never been isolated, and has only a theoretical existence. No argument is necessary to prove that CO₂ is an anhydride, for no one disputes it. I did not charge Mr. Bishop with supposing that "carbonic dioxide of the air occupied the whole space;" but I stated in effect that if his theory was correct the stratum of the air in contact with animal life would consist mainly or entirely of carbonic acid, in which animal life is impossible. To make the sentence intelligible to him I ought to have qualified the word "stratum" with some such addition as "lowest," or "in contact with the earth," though it was scarcely necessary, as the context implied that the stratum in question was that in which in an ordinary atmosphere animals live. I was referring to his astounding doctrine, "this is one of the wise provisions of Nature, so that the carbonic dioxide of the atmosphere (being one of the heaviest vapours we have) falls to the ground."

Small as is the quantity of carbonic acid in the atmosphere, averaging only four volumes in 10,000, it is quite sufficient, if it did really fall through its superior weight to the ground, to make the stratum of air in contact with the ground to consist only of carbonic acid, and be incompatible with animal life.

Mr. Bishop repeats his extraordinary delusion as to the behaviour of mixed gases in his last letter, when again utterly ignoring the recognised law of the diffusion of gases. He asserts, "If the gas were lighter it would all ascend"—that is, the atmosphere, instead of consisting mainly of a mixture of nitrogen, oxygen, and carbonic acid intimately associated, the proportions of each in given quantities only varying in infinitesimal degrees, it would consist of a stratum of carbonic acid in contact with the surface of the earth, above which would lie a stratum of oxygen capped by one of nitrogen. This being a fair sample of Mr. Bishop's scientific teaching quite justifies my strictures on his first article on the treatment of soils and manures. I have not dealt with those which followed, as the first was sufficient for my object of warning such of your readers as had not studied the

nature and properties of artificial manures, not to accept his dicta as to their value in comparison with stable manure without further inquiry or trial. I hope this object is attained; at any rate, I have finished, and shall not prolong a discussion which involves so much repetition, and is so technical that it cannot be interesting to the majority of your readers.—EDMUND TONKS.

JOTTINGS.

THE recent settlement of a *cause célèbre* in the Chrysanthemum world has attracted some attention to certificates, and the rules which regulate these awards. At the present time there are only two bodies of experts who bestow certificates which may claim to possess some official value, and these are the Floral Committees of the Royal Horticultural and National Chrysanthemum Societies respectively. Judges at provincial and other shows frequently award certificates for novelties, and these when signed by well-known competent men are reliable and valued distinctions, still the certificates of one or both of the Societies named add materially to the reputation of any new variety. At both the decisions are taken by voting, the majority for or against determining whether an award be granted or not; but a different procedure is followed when two or more exhibitors show the same variety at the same time. At the Royal Horticultural Society's meetings, when the same species or variety of plant is exhibited by different persons, and it is determined to be worthy of a certificate, the award is made to each exhibitor, and I remember one case (*Angræcum* or *Eranthus Leoni*) when no less than five certificates were granted at one meeting in this way.

The National Chrysanthemum Society adopt a different and, to some extent, a better course. One of the rules of the Floral Committee is to this effect, "In the event of any variety being staged by more than one exhibitor at the same meeting, the whole of the exhibits of that variety shall be submitted simultaneously, and the awards made (if any) shall be made to the exhibit or exhibits staged in the best condition." The result of this is that when, as often happens in the case of the imported French varieties, several examples are staged at one meeting, the best representatives of the variety are selected, and the award is made to these only.

As regards the imported varieties, there can be no doubt this is the best plan, as the same Chrysanthemum may be in the possession of twenty growers, but some difference of opinion exists with regard to sports or seedlings raised here. Instances have occurred where the same sport has occurred in several collections about the same time, or it has been distributed with others before the distinctness was recognised; then each possessor has thought it worthy of a special name, and thus the same variety has been brought before judges or committees under different titles, and it has sometimes been a difficult matter to determine which was entitled to precedence. The rule is that the name first published as officially recognised must be adopted in preference to all others, and after a variety has been thus distinguished it would be unjustifiable for anyone also possessing the variety and knowing they were identical, to bestow another name upon it.

In my opinion the best mode of removing the difficulty would be to require that exhibitors of new varieties should state distinctly whether their plants are imported, or home-raised seedlings, or sports. Then for the imported varieties only one certificate each should be awarded to those considered worthy of it, and, in accordance with the rule now in force, only to the blooms regarded as best representing the variety. For home-raised sports or seedlings certificates should be awarded in all cases where they are sufficiently distinct and in good condition at any meeting during the same session. This would avoid the danger of distributing certificates too freely, as it would be seldom that a sport or seedling could be shown by more than two or three exhibitors in one year. It could not be adopted for imported varieties, as these are frequently in the possession of a score or more of growers, and it would be inconvenient and undesirable to accord certificates to all who like to submit the same variety to the Committee. It appears desirable there should be some alteration in the existing rule, and I make the above suggestion as a possible means of rendering this evidently important matter more satisfactory.

Concerning the decision of the arbitrators in the case referred to, there is a very general opinion that, in the absence of any explanation of the course taken, it is illogical and unfair. It is true that only a portion of the decision was published, and no reason was assigned why, having really given a decision in favour of the defendant, and practically acquitted him of the actions imputed to him, he was yet called upon to pay a portion of the costs of the case. It is not encouraging to litigants to adopt arbitration as a means of settling their disputes, and

is, no doubt, unsatisfactory to both parties. Why such a case should ever have been commenced is a puzzle to many, and had the plaintiff taken the advice of his friends early in the year, he would have saved himself and others a considerable amount of expense and trouble. There are times when it is desirable to call in the aid of the law for the settlement of disputes, but in trade matters generally it is far better to come to some amicable arrangement without having recourse to legal advice.

The announcement of the opening of the public metropolitan shows of Chrysanthemums at the Inner Temple Gardens, Finsbury, Southwark, and other parks indicates the rapid approach of the exhibition season, and intending competitors already begin to count their chances of success. The prospect seems to be a good one, and all concerned with our favourite autumn flower are looking forward to a busy and interesting season. With regard to the metropolitan exhibitions just mentioned, there is every evidence of their fast increasing popularity in the large numbers of persons attracted to them, and there is no question that they perform a useful service in showing the inhabitants of towns what can be accomplished with the Chrysanthemum under unfavourable circumstances. This has become so evident that in several provincial towns the example set in London has been followed, and free public exhibitions provided during October and November.

With regard to length of time and valuable services rendered to the Chrysanthemum cause, the Show at the Inner Temple stands pre-eminent. It is quite an historical affair, and is looked upon as one of the events of the year in the City, and many an annual pilgrimage has been made from a distance to inspect the display and note the varieties. No attempt has ever been made to grow the plants to the highest exhibition standard of excellence, for it is rightly contended that it is better to show the public what a good proportion can fairly expect to attain, than the best results of a specialist's skill, which can only be secured by long experience and constant care. It will therefore be an unwelcome surprise for many to hear that it is rumoured this year will see the last of the Temple Shows, and it is to be hoped that time will prove the rumour is unfounded.

Mr. S. Broome had charge of the Inner Temple Gardens for a number of years. I do not know how many, but the first edition of his little pamphlet on the Chrysanthemum appeared in 1857, and the gardens were then noted for their collection. Mr. Broome died in January, 1870, and was followed in the same year by Mr. John Newton, who has during the nineteen years that have elapsed provided an annual display of much interest, which by the liberality of the Benchers has been thrown open to the public for several weeks during October and November of each year. Hundreds of thousands of people have visited the gardens in that time, and it is impossible to estimate the influence exerted in the popularisation of the Chrysanthemum. Undoubtedly it must have been great, and we shall regret to find that the privilege has been finally withdrawn.

Pedigree Roses have attained some fame in the United States, and now in return our American cousins promise us Pedigree Chrysanthemums, and the first of these is announced under the name of *Ada Spaulding*. This is described as the result of a cross between *Mrs. Wanamaker* and *Puritan*, neither parents being familiar to British growers, and it is said to possess all the good qualities of the best incurred varieties. Indeed Mr. John Thorpe says, "The flower is very large; the base of a bright rosy lilac, turning to pure white. It can rank with *Empress of India*, *Queen Victoria* (*Queen of England*), and *Lord Alcester*." Mr. R. Owen, who is the agent here, however, states, "The colouring is quite novel and distinct; the lower half of a rich deep pink shaded with bright purple rose. The upper half is of the pearliest white, the petals fully one-fourth of an inch wide, and the flower in size surpasses *Princess Teck* or *Jeanne d'Arc*." We must not, however, build our hopes too high, for it is evident the American standard of Chrysanthemum perfection is quite different from our own, judging, at least, by the majority of the varieties that have yet appeared.—L. CASTLE.

CHRYSANTHEMUM LADY T. LAWRENCE.

I HAVE read the letter of Mr. Jameson in your issue of the 26th ult., and your note at the foot of it. I should also be glad to "know the cause or probable cause" of the malformation of the buds of this Chrysanthemum, if it is its usual habit, and if anything can be done to avoid a repetition of this peculiar growth. This is the first year I have grown it, and though my plants are quite healthy in appearance the buds are exactly the same as those described in your note. Two buds out of three on one plant grew in the same manner, the third has not developed sufficiently at present to show whether it will take the same form of growth.—C. J. H.

PUBLIC CHRYSANTHEMUM EXHIBITIONS.

THE ninth annual display of Chrysanthemums in Finsbury Park is now open to the public from 10.30 A.M. till dusk, and will continue daily (including Sundays) to the end of the season.

The Chrysanthemum Show at Southwark Park, S.E., was opened to the public (free of charge) last Wednesday, 9th inst. The Show will be open during the season from 10 A.M. to dusk.

The Inner Temple Show will be opened on November 18th, when the public will be admitted as usual by permission of the Benchers.

CHRYSANTHEMUM EDOUARD AUDIGUIER.

Now that I have my Chrysanthemums housed I find Edouard Audiguier plays me the same old trick; the florets are browning, and going rotten long before the bloom is fully out—in fact, it is only just expanding. I took the precaution to house it early, and it has only had plain water for three weeks, having taken this precaution thinking overfeeding might have done the deed last season. Can any of your readers help me to a solution of the puzzle?—WORDSWORTH.

[The defect is to a large extent constitutional, but the specimens sent are much too gross, the wood soft, unripened, and hollow. The plants have been treated too generously.]

THE CHISWICK CHRYSANTHEMUM CONFERENCE.

A MEETING of the Executive Committee of the Royal Horticultural Society's Conference at Chiswick, which takes place on November 5th and 6th, was held on Tuesday last, October 8th, in the Council room, at the offices, 117, Victoria Street, when the following members were present—Shirley Hibberd, Esq., in the chair, and Messrs. A. F. Barron, L. Castle, N. Davis, J. Douglas, T. B. Haywood, W. Holmes, R. F. Jameson, C. Orchard, C. E. Pearson, G. Paul, H. J. Veitch, J. Wright, W. Wildsmith, and the Rev. W. Wilks. The principal business was forming the committees of selection and determining the manner in which the awards of certificates, as at the Vegetable Conference, should be accorded to exhibits. After some discussion it was decided to classify the varieties as follows, the under-mentioned members of the Committee being appointed to adjudicate in the respective sections. Varieties suitable for outdoor cultivation—Messrs. H. Cannell, W. Wildsmith, and H. M. Pollett. Incurved specimen blooms—Messrs. J. Wright, D. Donald, and W. Mease. Japanese—Messrs. W. Holmes, E. Wills, and R. F. Jameson. Reflexed Anemones, Pompons, and Singles—Messrs. L. Castle, C. Orchard, and N. Davis. Varieties of all classes for named specimens—Messrs. Beckett, Berry, and J. Laing. Varieties suitable for decorative plants—Messrs. C. Herrin, R. Owen, and W. Furze. Referees, or Reserve Committee, were Messrs. H. J. Veitch, E. Molyneux, R. Parker, and H. Payne. The Committees are to meet at 11 A.M., but the Floral Committee also meets at that hour, and all new varieties entered for certificates must be submitted to that body.

MESSRS. JAS. VEITCH & SONS, LANGLEY NURSERY.

CUT in twain by the Slough branch of the Grand Junction Canal, yet is this large nursery of some ninety acres compact in form and full of exceeding interest to all privileged to pass within its gates. Of course I assume that the visitors are persons like myself who are on instruction bent, and privileged indeed is the gardener who has in his earlier years been enabled to become familiar, for some time at least, with the exceedingly admirable and capable manner in which work of all kinds is performed in a first class nursery. Whilst at Langley we find something of everything almost, yet is the nursery chiefly devoted to the culture of fruit stock, and superb stock it is indeed; but a visit for a part of a day to any man who keeps his eyes open is an educational object lesson, the which may serve him in good stead for the rest of his days. The ways of nurserymen may not be mysterious or past finding out, but at least they are severely practical and intensely useful. Work is well done, it is performed on the most modern lines, and with the best rules of practice. It is performed on a large scale with an exceeding variety of subjects, and with perfect order and discipline. Even in the matter of studying the art of getting work well and quickly done a turn in a nursery is full of value, and especially so is it when the study is performed in such a first class school as the Langley Nursery presents. When I called there the other day—chiefly to see the Apples, of which they have had a very good crop, and the fruits generally superb—I could not but remark the numerous varieties of flowers being grown for seed, the capital nature of the strains, all indeed of the very best. The full appearance of the seed yard, literally crowded with stock of various flower and vegetable seed crops, Peas, Beet, and Celery, and noted with exceeding pleasure the great care bestowed upon each variety, and in securing the seed products in the highest condition. Mr. Scott, who manages this establishment for the firm, has everything at the tip of his tongue, and looking at the exceeding variety of subjects which come under his control, it is indeed needful that he should be a sort of human encyclopædia.

A recent and very important addition to the features of the Langley Nursery has been made, for away in one corner of a big meadow beyond the stock yard has been erected some capital low span houses, in which are now deposited that interesting and wondrously varied family of juvenile Orchids of which Mr. Seden is the protective father, guardian, and friend. Mr. Seden, with all his household gods, has been transported from the fogs of Chelsea to the purer air of Langley, a roomy house having been erected for him close to the nursery, in which his numerous and varied family of liliputian Orchids now dwell; not that all are small, for many of the plants are just coming to the flowering size, but there are thousands of mere pigmies in the tiniest of pots, and myriads also of seedlings not even yet transferred from the seed pots, the which, should Mr. Seden be spared, he may hope to see blooming some eight or ten years hence. Well have the Messrs. Veitch & Sons done to remove all this precious and valuable progeny to purer regions than Chelsea presents, for are not all more or less the products of hybridisation? and they may prove to be swans or geese only, but problematically their value must be great indeed. Orchid seed is excessively small. Mr.

Seden shows a Cattleya pod opened containing a mass of what appears to be the finest of pollen grains, but all are seeds none the less, and all are sown, and how? There again is a curious experience manifested, the which a man may be the most expert of growers and yet never hear of. Why, the very best seed bed for these tiny seed particles, these infinitesimal embodiments of some future hundred-guinea hybrids perhaps, is found on the sphagnum which surfaces the 2½ or 3-inch pots, in which myriads of three, four, or five year old seedling plants are growing. In such odd material do these particles germinate far more readily than if sown in pans or pots alone, or in any other fashion.

However, there is a wide interval botanically between Orchids and Apples, and as I went to Langley to see the Apples to Apples must I now revert, and the first thing to say in reference to them is that whilst sparse crops seem to have ruled generally, there appears to have been no lack of fruit at Langley, and if any solution of the great Apple-producing question is needed it seems as if it must of necessity be looked for in the nursery methods of culture, myriads of small trees—bush, pyramid, or trained—planted thickly, and for their dimensions fruiting abundantly. Then, again, as at Langley, Apples seem to come only in their true character when grown in this fashion. The smaller fruits on old or standard trees with which we are generally familiar are here seen in such enlarged, indeed monstrous form, as to be almost unrecognisable, so huge, so superbly developed, and so richly coloured and finished are they. My visit to Langley was made fully a fortnight late, and especially so this season, when the unusual September heat and drought have made the fruits to fall early everywhere. To have got there before any fruits were gathered for the autumn shows would have been a treat indeed, and I hope to experience that joy another year, when notes on Apples may be made with greater exactness. There were plenty of fine samples of the various gathered kinds in the fruit rooms, but the beauty in Apples is never more realised than when seen hanging on the trees, and especially on the young nursery trees, of which there are tens of thousands at Langley in the highest degree of robust healthy growth and setting first spurs in the most remarkable way. Myriads of these trees purchased in October and early in November, planted carefully, and the roots slightly protected with a little mulch of long manure, will carry superb fruits next year. Indeed there should be hardly one Apple tree in growth but what should produce fruits more or less next year, so favourable to fine bud development is the present autumn. There runs right through the nursery at Langley from the Slough side to the Langley end a broad cart-road some third of a mile perhaps in length. That road is bordered on either side by dwarf bush or pyramid trees of Apples, Pears, Cherries, &c., but the whole of one side is occupied by Apples; three trees of every kind, here and there six trees, being planted in rows thickly, and, as far as practicable, the sorts are grouped into families, such as Pearmains, Nonpareils, Pippins, Russets, Codlins, and so on, so that if any one kind be met with its comparative allies are sure to be found close at hand, and thus comparison is more readily instituted.

To have dealt with these myriads of kinds as there prevailed was not possible to me the other day. They could only be dealt with when the whole were fruiting and time was abundant. Certainly when performed—and it needs doing well—the work of comparison of kinds in their sections will be an interesting one. Amongst the Apples which attracted attention the Reinettes came first, and a striking kind was Werder's Reinette, not unlike Court Pendû Plat in form, but finer, with the colour of Bleinheim Pippin, a fine cropper, good keeper, and the tree makes a capital pyramid. The old Golden Reinette, very handsome, cropping freely, and of the finest quality; Reinette du Caux, very handsome, round fruits, striped, of medium size, a splendid dessert variety; Reinette Jaune Hâtive, fruits of rich colour and highly perfumed, ripens in August, was commended as a first-class early dessert sort; Winter Pearmain, in a wonderfully fine form, colouring richly, a very beautiful Apple; Scarlet Pearmain, brilliant in colour, handsome, conical form; Hornead's Pearmain, very handsome, conical, good size and solid, a beautiful fruit, and keeps well, first-class quality; Herefordshire Pearmain, a capital old kind, not commonly met with, good, late keeper; Baumann's Red Winter Reinette, rich red, tree a fine cropper, keeps well, a superior market Apple; Baxter's Pearmain, conical, like fine King of the Pippins, keeps well till March; Balchin's Pearmain has protrusions at the stem like Lemon Pippin, but keeps colour, a fine keeping variety; Adams' Pearmain, well known and good; Lane's Prince Albert, fruiting freely, quite a picture, should be universally grown for market on dwarf trees; Peasgood's Nonesuch, wonderful samples on these small trees; North End Pippin, a handsome and large conical shaped variety; Northern Greening, a fine crop; Early Nonpareil, pretty yellowish round, excellent for dessert; Mrs. Barron, a superb conical Apple, yellowish skin with some colour, a grand variety; American Mother, delicious quality, and good conical form; Margil, fruiting finely and freely; Lord Derby, one of the finest of the Codlin type, and fairly good keeper.

Lord Nelson, not unlike Cellini Pippin, a fine cropper, and wants to be better known; also Nelson Codlin, a moderate growing, free cropping kind, fruit like Lord Suffield, but greener and keeps longer; Lady Henniker, a capital keeping sort; London Pippin, a pretty round variety; the old Lemon Pippin and King of the Pippins, the latter especially wonderfully fine; Jonathan, an American variety for dessert purposes, conical, coloured, handsome, and a free cropper; Withington Fillbasket, a huge fruiter, like Ecklinville, but free from speck; Cornish Gillyflower, very beautiful; Lewis's Incomparable, fine red fruited kind; Winter Hawthornden, fruiting grandly according to statement;

Niton House, a medium sized, handsome, free fruiter, pale lemon in colour, and roundish, a grand cropper; Calville Rouge Précoce, like an intensely red Cellini, a very beautiful Apple; Large American, a big, square-shaped fruit; Cumberland Favourite, large, rich coloured, of the Manx Codlin form, but later and more assured cropper; Domino, now getting a high reputation for its excellent qualities; Hoary Morning, superbly coloured samples; Herefordshire Beefing, also beautifully coloured; Gravenstein of Germany, flattish, striped, free cropper, but distinct from the ordinary early Gravenstein; Gipsy King, a fine, handsome form of Sam Young, but better; Gascoigne's Seedling, rich red, free cropper, should be popular in markets; Egg Apple, true egg shaped, smooth and handsome, fine for dessert, ripe in November; Wellington, fruiting finely and freely, on these young trees a beautiful sample; Devonshire Queen, bright reddish coloured variety, nearest to Hoary Morning, early dessert, and very fine quality; Court of Wick and Downton Pippin, both condemned at the late Apple Conference, but beautiful and capital samples here, delicious quality; Ladies' dessert Apples; Cockle Pippin, very fine and free; Colonel Harbord, fine flattish round fruit, highly russetty, great cropper, and good keeper; Castle Major, flattish, square variety, fine keeper, Cellini Pippin in very beautiful form; Calville Malingre, very handsome, conical fruit, not unlike large Worcester Pearmain; Bismarck, in grand form and colour, a superb Apple for market and general use; Watson's Tyler's Kernel, one of the finest of recently introduced varieties, conical, rich coloured, and a good keeper; Blenheim Pippin, on small trees, carrying wonderful fruit, exploding the theory about planting it for posterity only; Belle Dubois, not Gloria Mundi here, but quite diverse and a fine variety; Belle Du Havre, rich red, flattish round, and very handsome; Barnack Beauty, stem set in small base, reddish striped, a handsome pyramid, and great cropper; Bramley's Seedling, a very great cropper, and a fine late keeper; Betty Geeson, fine; Alfriston, good; Allen's Everlasting, a flattish round, long keeping Apple of good flavour; Annie Elizabeth, Court Pendu Plat, beautiful samples; Paradise Pippin, very early dessert, rich colour, one of the very best for early work; and Lady Lennox, of Hawthornden style, deep green colour, with reddish flush, very fine cropper.

Now this lengthy list must conclude, and yet it represents but a few of the numerous sorts growing at Langley. Enough has been mentioned to show that the Messrs. Veitch have spared no trouble to get together not merely one of the finest, but perhaps the largest and most truly representative collection of Apples to be found in the kingdom. It is expected that shortly, probably early in October, the firm will show a collection of some 250 varieties at the Drill Hall. It will be a remarkable sight, and a matter to be deplored that so few of the public will see them there.* Let us hope that next year, with the aid of the Fruiterers' Company and some other powerful bodies, a really grand show of fruit may be held in London, as, amidst all the talk about hardy fruit culture, the general public sadly want enlightening as to the merits of the wondrous variety of sorts of Apples now in commerce.—D.

THE VEGETABLE CONFERENCE.

THE following is an official list of the certificates awarded by the Jurors at the Chiswick Conference recently:—

GREEN VEGETABLES.

Cabbage.—Ellam's Early, from Mr. J. Willard; Old Nonpareil, from Messrs. J. Carter & Co.; Hâtive d'Etampes, from Messrs. Vilmorin, Andrieux & Co.; Offenbam, from Messrs. J. Harrison & Sons; Hardy Green Colewort, from Messrs. J. Veitch & Sons and Mr. W. Poupart; Rosette Colewort, from Mr. W. Poupart; Early Flat White Drumhead, from Messrs. J. Veitch & Sons; Red Dutch, from Dobbie & Co. and Mr. R. Gilbert.

Savoy.—Early Ulm, from Messrs. J. Veitch & Sons; Dwarf Green Curled, Messrs. J. Veitch & Sons and Mr. W. G. Gilbert; Vertus, from Messrs. J. Veitch & Sons.

Chou de Burghley, from Mr. R. Gilbert.

Borecole.—Extra Dwarf Green Curled and Cottagers' Kale, from Messrs. J. Veitch & Sons.

German Kale.—Dwarf Scotch, from Mr. H. Hanan.

Green Kale.—Dobbie's Selected, from Messrs. Dobbie & Co.

Brussels Sprouts.—Deverill's Large Wroxton, from Mr. H. Deverill; Paris Market, from Messrs. J. Veitch & Sons.

Cauliflower.—Pearl, from Messrs. J. Veitch & Sons; Veitch's Autumn Giant, from Mr. J. Lambert.

Artichoke.—Green Globe, from Mr. J. Lambert.

Spinach.—Vioflay, from Mr. R. Smith; Prickly Seeded, from Mr. W. Poupart.

FRUITS AND PULSE.

Marrow.—Anglo-Indian, from Mr. E. Chadwick; Long White, from Mr. W. Palmer; Moore's Cream, from Messrs. R. Veitch & Son; Hibberd's No. 1, from R.H.S.; Long White Bush, from Messrs. Vilmorin, Andrieux & Co.; Pen-y-Byd, from Mr. J. Muir.

Gourd.—Large Yellow Mammoth, from R.H.S.

Pumpkin.—Rouge de Crimée, from R.H.S.

Squash.—Yokohama, from Messrs. Vilmorin, Andrieux & Co.

Cucumber.—Lockie's Perfection, from Mr. T. Lockie.

Tomato.—Chemin and Mikado (scarlet), from Messrs. Vilmorin,

Andrieux & Co.; Chiswick Hybrid, Advancer, Golden Queen, Tennis Ball, from R.H.S.; Ham Green Favourite, from R.H.S., Mr. R. Dean, and Messrs. J. Veitch & Sons; Golden Queen, from Messrs. J. Veitch and Sons; Perfection, from Mr. W. Poupart and Mr. R. Dean.

Bean (Runner).—Neal's Ne Plus Ultra, from Mr. G. Neal and Mr. H. D. Deverill; Jubilee Runner, from Mr. C. J. Waite; Early Golden Cluster (butter) and Fillbasket (butter), from Messrs. J. Veitch and Sons; Sutton's (butter), from Mr. R. Gilbert; Dwarf Canadian Wonder and Dwarf Mobawk, from Mr. G. Wytbes.

Pea.—Duke of Albany, Telephone, Prodigy, and Sutton's Matchless, from Mr. J. Lambert; Ne Plus Ultra and Carter's Stratagem, from Mr. J. H. Goodacre.

Capsicums.—Golden Queen and Large Bell, from Messrs. Vilmorin, Andrieux & Co.

Maize.—Extra Early Sweet, from Messrs. Vilmorin, Andrieux and Co.

TAP ROOTS.

Parsnips.—Dobbie's Selected Hollow Crown, from Messrs. Dobbie and Co.; Improved Hollow Crown, from Messrs. J. Veitch & Sons; Hollow Crown, from Mr. W. Poupart.

Beet.—Edinburgh Blood Red, from Mr. Hugh Hanan; Dewar's Dwarf Red and Eclipse (Turnip-rooted), from Messrs. J. Veitch & Sons; Dobbie's New Purple, from Messrs. Dobbie & Co.; Dracæna-leaved, from Vilmorin, Andrieux & Co.; Cheltenham Green Top, from Messrs. Harrison & Sons, Mr. W. Poupart, Mr. F. Taylor, and Mr. G. Wythes; Middleton Hall Favourite, from Mr. H. Deverill; Carter's Turnip-rooted, from Messrs. J. Carter & Co.

Carrot.—New Scarlet Improved Short Horn, from The Novelty Seed Company; Early Very Short French Horn, Guérande, Long Red St. Valery, from Messrs. Vilmorin, Andrieux & Co.; Sutton's Gem (Guérande), from Mr. J. Lambert; Sutton's Early Gem (Guérande) and Red Intermediate, from Mr. J. Lye; Long Red Surrey, from Messrs. J. Veitch & Sons; Carter's Scarlet Perfection (St. Valery), from Mr. W. Cbettleburgh.

SALADING.

Celeriac.—Large Smooth Prague, from Messrs. Vilmorin, Andrieux and Co.

Celery.—Wright's Giant, from Messrs. Oakshott & Millard; Dobbie's Invincible, from Messrs. Dobbie & Co.; Sandringham White, from Messrs. J. Veitch & Sons; Sutton's White Gem, from Mr. J. Lye; Aylesbury Prize Red, from Mr. H. Deverill; Standard Bearer, from Mr. F. Taylor; Covent Garden Red, from Mr. W. Poupart.

Chicory (Witloof).—From Messrs. J. Veitch & Sons.

Radish.—Long Scarlet, Early Scarlet Forcing, and Early White Forcing, from Messrs. Vilmorin, Andrieux & Co.

Endive.—Improved Round-leaved Batavian, from Messrs. J. Veitch and Sons; Broad-leaved Batavian, Ruffec, and (Moss Curled) Chicorée Parisienne d'Été, from Messrs. Vilmorin, Andrieux & Co.; Moss Curled, from Messrs. J. Veitch & Sons.

Salsafy.—From Mr. R. Smith.

Lettuce (Cabbage).—Lorhois and Blonde Berlin, from Messrs. J. Veitch & Sons.

Parsley.—Myatt's Curled, from Mr. R. Dean; Dobbie's Selected, from Messrs. Dobbie & Co.

BULBS AND TUBERS.

Leek.—Lyon, from Messrs. Stuart & Mein, Messrs. Dobbie & Co., Mr. J. Lambert, and Messrs. R. Veitch & Son; Musselburgh, from Mr. C. J. Waite and Mr. J. Lambert.

Onions.—Giant Late White Flat Tricoli, Giant Madeira, and Large Blood-red Flat Italian, from Messrs. Vilmorin, Andrieux & Co.; Queen, Brown Globe, and Southport Red Globe, from Messrs. J. Veitch & Sons and R.H.S.; Giant Zittau, from Messrs. R. Veitch & Son, Exeter; Brown Spanish, from Messrs. J. Veitch & Sons; Main Crop, from Mr. Nicholas; Deverill's Improved Wroxton, from Mr. W. Pope; Anglo-Spanish, from Messrs. Oakshott & Millard, Mr. W. Pope, and Mr. Wingrove; Bedfordshire Champion, from Mr. G. Wythes; Flat Yellow or Brown Anglo-Spanish, Pinesfield, Advancer, and Cocoa Nut, from Mr. H. Deverill; Black Douglas, from Mr. H. Deverill and Mr. D. Murray; Rousham Park, from Mr. W. Pope, Mr. C. J. Waite, Mr. Bowerman, and Mr. H. Deverill; Ailsa Craig, from Mr. H. Deverill, Mr. W. Pope, Mr. W. G. Gilbert, Mr. J. Hughes, and Mr. R. Kneller; James' Keeping, from Mr. Muir, R.H.S., and Mr. H. Deverill; Reading, from Mr. J. Hughes; Blood Red, from Messrs. Dobbie & Co.

Shallots.—Large Red, from Messrs. Stuart & Mein.

Garlic.—From Mr. R. Smith.

Turnips.—Early Milan (Red-top), Snowball, Round Red Globe, from Messrs. J. Veitch & Sons; White Stone, from Messrs. J. Veitch & Sons and Mr. J. Lambert; Model White Stone, from Messrs. Dobbie & Co.; Golden Ball, from Messrs. J. Dobbie & Co. and Mr. J. L. Ensor; Early Marvel, from Messrs. Harrison & Sons; Round Red Globe, from Messrs. R. Veitch & Son; Green-top Stone, from Mr. R. Maher.

Kohl Rabi.—Early Vienna, from Messrs. J. Veitch & Sons and Messrs. J. Carter & Co.; purple, from Mr. C. Osman and Messrs. J. Veitch & Sons.

Potatoes.—Reading Russet, from Mr. J. Hughes and Mr. W. Wildsmith; Reading Ruby, from Mr. J. Hughes; Reading Giant, from Mr. J. Lye, Mr. J. Hughes, and Mr. E. S. Wiles; King of Russets, from Mr. J. Lye; Snowdrop, from Mr. E. S. Wiles; London Hero, from Mr. E. S. Wiles and Messrs. R. Veitch & Son; Sutton's Abundance, from Mr. W. Wildsmith, Mr. J. Lambert, and Mr. J. Hughes; Adiron-

* Referred to in the report of the meeting on page 318.

dack, Early Puritan, from Messrs. J. Veitch & Sons; Favourite, from Mr. E. S. Wiles; Veitch's Improved Ashleaf, from Mr. J. Hughes; Wordsley Pride, Epicure, Renown, from Messrs. E. Webb & Sons; Sutton's Seedling, from Mr. J. Lambert and Messrs. Geo. Bunyard and Co.; Prime Minister, from Mr. J. Lambert; Sutton's Abundance, from Mr. J. Lambert and Mr. J. Hughes; Cole's Favourite, from Mr. J. Lambert; Vicar of Laleham, from Messrs. R. Veitch & Son; The Rector, Edgcote Purple, Sutton's Reading Ruby, Prolific, Sutton's Magnum Bonum, Edgcote Early, Edgcote Beauty, from Mr. E. S. Wiles; Hughes' Perfection, from Mr. J. Hughes; Hughes' Pink Perfection, from Mr. J. Hughes; The Dean, Beauty of Hebron, from Mr. J. Lye; Carter's King of Russets, from Messrs. J. Carter & Co.; Chancellor, Webb's Renown, from Mr. J. Lambert.

Potatoes (cooked).—Victory, from Mr. J. Lye; Duchess of Fife, from Mr. J. Hughes; Edgcote Early, from Mr. E. S. Wiles; Talisman, from Mr. C. Ross; Conference, from Mr. R. Dean; The Gentleman, The Cottager, from Mr. R. Maher; Victorious, from Mr. T. Laxton.

ROYAL HORTICULTURAL SOCIETY.

OCTOBER 8TH.

THE exhibition of Apples at the meeting held in the Drill Hall, James Street, Victoria Street, on Tuesday last, was an exceedingly fine one, both in the number of the varieties and the excellence of the specimens. Beyond these there were three capital groups of small Conifers, the collection of Retinosporas being probably the best ever shown. Miscellaneous plants and Orchids also furnished attractions, while Mr. Coleman's lecture on Conifers was listened to attentively by a good number of visitors.

FRUIT COMMITTEE.—Present—Sir C. W. Strickland, Bart., in the chair, and Messrs. R. D. Blackmore, Harrison Weir, W. Bates, G. Bunyard, W. Warren, W. Wildsmith, G. Wythes, H. Balderson, G. W. Cummins, F. Q. Lane, J. Cheal, J. T. Saltmarsh, and J. Wright.

A dish of Kane's Seedling Apple was placed on the table from Mr. George Dyke, gardener to H. F. Pocock, Esq., Kirklington Hall, Southwell, understood to have been raised by the vicar of that parish, whose name it bears. The fruit is above medium size, roundish, straw colour, with a delicate flush on the sunny side. It is highly perfumed, with a sweet tender flesh. The Committee, in the absence of information of the character of the tree, did not feel justified in recommending a first-class certificate, but ten members voted that an *award of merit* be recorded for the fruit.

A dish of South Lincoln Beauty Apple, said to be a seedling from Cox's Orange Pippin, and somewhat resembling it in shape, but not at present in flavour, was sent by Messrs. W. & J. Brown, Stamford, and the Committee desired to see it again, also Duncombe Seedling, a late conical Apple, and Toogood's Seedling, sent by the same firm, the latter somewhat resembling Golden Noble.

Messrs. J. & A. Cheal sent a dish of highly coloured fruit of the Forge Apple of Sussex, also cooked fruit. The variety in this bad fruit year is the mainstay of Sussex growers, and the trees are not affected by canker or caterpillars. The Chairman found it equally good in Yorkshire. It is excellent for cooking and cider. It was commended for its hardiness, fertility, and certainty in bearing. The fruits are, as a rule, somewhat small, but would no doubt be larger from young and less heavily cropped trees. It is useful and worthy of trial in different parts of the country.

Messrs. W. Paul & Son, Waltham Cross, sent handsome specimens of Mabbot's Pearmain Apple, and a cultural commendation was unanimously awarded. It has some resemblance to Golden Reinette, but is much more highly coloured. Mr. John Gow, Reading, sent a dish of John Harris Apple, apparently an inferior form of King of the Pippins. It was passed. Mr. Dean, Ealing, sent a Crab to be named. It was regarded simply as a common form of the common Crab.

Mr. Maher, The Gardens, Yattendon Court, Newbury, sent handsome fruits of Golden Perfection Tomato, but they were too ripe and soft for determining the flavour. Mr. Dean sent a bottle of Vegetable Marrow jam, in which the predominating flavour was ginger.

Mr. W. Roupell sent ripe July Frontignan Grapes grown in the open, and a vote of thanks accorded.

Some very extensive and valuable collections of fruit were exhibited, and medals, which they deserved, recommended for them.

The last named gentleman exhibited fifty dishes of Apples grown in his garden at Streatham within the five-mile radius from Charing Cross. Several of the specimens were very fine indeed, and the whole highly commendable (bronze medal).

Messrs. J. & A. Cheal exhibited 170 dishes of Apples and Pears, including enormous examples of Warner's King, Peasgood's Nonesuch, New Hawthornden, Stirling Castle, and many others, amongst which the Forge Apple was prominent by its glowing colour (silver medal). Messrs. James Veitch & Sons exhibited a wonderful assortment of fruit, containing excellent representative dishes of 93 varieties of Pears and 252 of Apples, some of the more prominent varieties being alluded to on another page (silver-gilt medal). Mr. C. Davies, gardener to Lady Howard de Walden, Mote Park Gardens, Maidstone, sent seventy dishes of magnificent Apples and Pears, also large dishes of Grapes, with a dish of Cherries and Currants, and the Committee marked their appreciation of the high culture displayed by the recommendation of a silver-gilt medal.

FLORAL COMMITTEE.—Present—W. Marshall Esq., and Messrs. Shirley Hibberd, R. Dean, W. C. Leach, R. B. Lowe, E. Mawley, T. W. Girdlestone, J. Walker, H. Herbst, B. Wynne, Lewis Castle, W. Holmes, Frank Ross, H. Cannell, C. Noble, and G. Paul.

Messrs. J. Veitch & Sons, Chelsea, had a stand of Rhododendron flowers, comprising several fine varieties, one of which, *Aspasia*, received an award of merit. A plant of *Begonia Prometheus*, a hybrid between *B. Froebeli* and a Tuberous variety, was also shown. The leaves large; the flowers of natural size and bright red. Mr. B. S. Williams, Upper Holloway, exhibited an admirable group of *Sarracenias*, *Crotons*, together with several interesting Orchids, *Oncidium ornithorhynchum* album being notable, as were also some good *Cypripediums* (silver medal). Mr. W. Smythe, The Gardens, Basing Park, Alton, sent sprays of *Jasminum revolutum*, with golden variegated foliage. Mr. R. Dean, Ealing, sent plants of *Pyrethrum uliginosum* in 48-size pots, small compact plants, in flower, that had been raised from layers. Messrs. Hawkins & Bennett, Twickenham, exhibited a stand of a dozen fine blooms of *Chrysanthemum Mrs. Hawkins* (vote of thanks). From the Society's Gardens came several plants of double Balsams (*Vilmorin's strain*); plants of *Liliput Asters* were also shown, small flowers of bright colours, crimson and rose principally.

Messrs. H. Cannell & Sons, Swanley, had an interesting collection of *Chrysanthemum* blooms, comprising good blooms of *Avalanche*, and very large examples of *Etoile de Lyon*. Flowers of *Abutilons* and Tuberous *Begonias* were also sent (vote of thanks).

Mr. G. Wythes, Syon House Gardens, Brentford, exhibited specimens of *Jambosa australis*, a New Holland plant, recommended for culture in pots; the leaves narrow, elliptical; the flowers greenish white with numerous white stamens, the deep crimson fruits being very ornamental.

A group of *Anthuriums* from Sir T. Lawrence, Bart., M.P., occupied a corner of the hall, and edged with small Ferns produced a fine effect, the plants being strong with enormous spathes, *A. Andreanum* and others of that type being principally represented (cultural commendation). These plants have long been well grown at Bedford Lodge, and the award was well merited. Messrs. Davis & Jones, Camberwell, sent a collection of *Chrysanthemums*, comprising grand blooms of *La Vierge* (vote of thanks).

Conifers.—Messrs. J. Veitch & Sons, Chelsea, had a group of choice Conifers in baskets, the specimens being from 2 to 7 feet high and compact, and beautiful examples of the best *Retinosporas*, including the following:—*R. obtusa*, *R. filicoides*, *R. pisifera nana aurea variegata*, *R. plumosa argentea*, *R. tetragona aurea*, *R. squarrosa*, *R. ericoides*, *R. filifera gracilis*, *R. obtusa alba spica*, *R. plumosa aurea*, *R. leptoclada*, *R. obtusa Keteleeri*, *R. filifera*, *R. plumosa flava*, *R. filifera aurea*, *R. plumosa alba picta*, *R. obtusa aurea*, *R. gracilis aurea* and *nana*, *R. lycopodioides*, *R. pisifera*, *R. obtusa pygmaea*, and *R. obtusa pyramidalis* (silver medal). Messrs. W. Paul & Son, Waltham Cross, had a large group of green and variegated Yews (bronze medal), and Messrs. G. Paul & Son, Cheshunt, sent a number of small specimen Conifers in pots, display varieties of Junipers and Cupressus.

ORCHID COMMITTEE.—Present—H. J. Veitch, Esq., and Messrs. J. Douglas, J. Dominy, H. M. Pollett, H. Ballantine, and E. Hill.

Exhibits were not very numerous, but one or two were of an interesting character. From Lord Rothschild, Tring Park (gardener, Mr. Hill), came a raceme of *Vanda coerulea* with eighteen flowers and buds, the former of an exceptionally good shape, and the blue tint finely developed. The plant had been grown in a Cattleya house, and placed right under the ventilators, where of course it was freely exposed to air in fine weather.

FIRST-CLASS CERTIFICATES.

Laelia autumnalis alba (J. Veitch & Sons).—Flowers of medium size, pure white with a slight dash of yellow in the throat of the lip.

Cattleya Hardyana Wrigley's variety (E. G. Wrigley, Esq., Howick House, Preston).—A grand variety, the sepals and petals purple crimson with lighter veins, the lip deep gold at the base, and an intense magenta at the tip, which is undulated, and some of the rich colouring runs down the base of the lip.

Laelia praestans alba (Wm. Bull).—A charming variety, the sepals and petals pure white, the base of the lip also white, the tip rich crimson.

Ceropegia Saundersi (F. Ross).—A botanical certificate was awarded for this peculiar trailing plant, the flowers strangely spotted with green.

Anthurium leodense (Sir T. Lawrence, Bart., M.P.).—A hybrid between *A. Veitchi* and *A. Andreanum*, with spathes 7 inches in diameter by 8 inches long, of a particularly rich shining red colour, the spadix large and white.

Lycaste flava, var. *Cumminsi* (A. H. Smee, Esq.).—A distinct variety, the sepals of a peculiar brownish green colour, the petals white, with a faint tinge of rose in the centre, and a rosy crimson lip.

Cypripedium picturatum (Sir T. Lawrence, Bart., M.P.).—A beautiful variety or hybrid, the dorsal sepal suggestive of *C. Spicerianum*, white with purple and green veins. The petals are greenish at the base, with a few crimson dots, the margin undulated with a few dark hairs, the lip and staminode of purple tint.

AWARD OF MERIT.

Rhododendron Aspasia (J. Veitch, Esq.).—A charming variety, pure clear yellow; the corolla large with rounded lobes, the truss compact.

Chrysanthemum Dorrie (H. Cannell, & Sons).—A rich golden yellow

Japanese variety, with long recurving florets, very handsome, and of good substance.

ALLERTON PRIORY.

ALLERTON PRIORY, the Lancashire residence of J. G. Morris, Esq., is situated about six miles from Liverpool. The house is a fine built structure, designed by Waterhouse, the celebrated architect of the Manchester Town Hall. The grounds have been tastefully laid out, and there are some fine trees of *Sequoia gigantea*, *Araucaria imbricata*, *Quercus*, and *Ilex*. The flower garden looked well, some of the beds being very effective. The kitchen garden appeared to be stocked with useful vegetables. In the orchard the fruit crop is not a heavy one, but the following were bearing satisfactorily:—Apples—Lord Suffield, Cellini, King of Pippins, Cox's Orange; Pears—Williams' Bon Chrétien, Beurré Clairgeau, Beurré d'Amanlis, and Durondeau; Plums—Kirke's, Dennison's Superb, and Magnum Bonum.

The glass houses constitute the chief feature at Allerton, there being some really fine and useful structures, the greater part devoted to fruit. In the early houses the crops were gathered, but the Peach trees and Vines looked clean and healthy. In a vinery where most of the Grapes were cut were hanging several good bunches of Madresfield Court and Black Hamburg, the former being exceptionally fine. Another large span-roof contained good bunches of Black Hamburg and Duchess of Buccleuch; the latter is a Grape that is seldom grown well, but still one of the best for flavour. In the late house were some good samples of Mrs. Pince, Lady Downe's, and Alicante. The Pines and late Peaches looked remarkably fine, as did also the Melons, Cucumbers, and Tomatoes. In the plant houses everything seemed to be perfectly clean and healthy. In the stove were some fine plants of *Ixoras*, *Dipladenias*, *Allamandas*, and *Bougainvilleas*, all in flower.

The greenhouse was bright with colour. *Abutilons*, *Ivy Pelargoniums*, *Liliums*, *Begonias*, and *Fuchsias* were flowering freely. I also noticed several pots of *Torenia Fournieri* in full bloom; it is a graceful plant, of easy culture, and flowers a considerable time. In the fernery were large banks of *Maidenhair* and some fine specimens of *Microlepias*, *Davallias*, *Todeas*, *Adiantum cuneatum*, *A. farleyense* being particularly fine. The houses are heated by two large horizontal tubular boilers; the stokehole is the largest I have seen, and for tidiness is a pattern for any young gardener, as these are generally the most neglected places in a gentleman's garden. The gardener, Mr. Craven, has greatly improved the establishment during the few years he has been there.—W. R.

THE DUTCH HORTICULTURAL SOCIETY.

THE Dutch Horticultural Society has resolved to follow the example of similar societies in England and elsewhere, and to award at its meetings, the dates of which will be fixed beforehand, certificates to growers of products belonging to the vegetable kingdom, plants, vegetables, and fruits which are remarkable for their novelty or exceptional qualities. For this purpose it has formed committees entrusted with the task of examining such products as are submitted to them. One is specially devoted to plants and flowers, another to vegetables and fruits. The third is a scientific committee for the examination of interesting and abnormal peculiarities which may be valuable to botanical science.

Each committee has the right to award first and second-class certificates according to the merits of the products.

The meetings this year were fixed for September 10th, October 23rd, and December 3rd.

It is intended to send after each meeting an extract of the proceedings of every committee.

We enclose with this request the report of the meetings yet held.—W. BARON VAN GOLTSTEIN (*President*), H. C. ZWART (*Secretary*), Amsterdam.

FLORAL COMMITTEE, JUNE 27TH.—First-class certificates awarded to Messrs. Zocher & Co. at Haarlem for a collection of branches and leaves of new or recently introduced trees and shrubs, among which were the *Pinus Strobus zebrina*, *Acer pseudo-platanus atro-purpurea*, *Acer negundo aurea marginata*, *Viburnum Tinus fol. aur. var.*, *Castanea japonica*, and Kelscy's Plum.

To Messrs. Jac. Jurrissen & Son at Naarden for their *Cupressus Lawsoniana Westernmanni* of very remarkable size and colour. To Mr. C. G. Overeynder at Apeldoorn for *Dimorphanthus mandschuricus fol. aur. var. elegans*.

To Messrs. E. H. Krelage and Son at Haarlem for a large collection of cut flowers and bulbs, among which were some *Gladiolus incomparabilis* Madame Blanche Bourdin and Palmyre, and among the *Iris Kämpferi* varieties were Alexander von Humboldt fl.-pl., Rainbow, with pure white flowers, and Princess.

Second-class certificates were given to Messrs. E. H. Krelage & Son at Haarlem for *Albuca Nelsoni*, a novelty introduced in 1886, and for a new variety of the *Iris Kämpferi* W. Cochrane with large and pure white flowers. The same firm also sent a nearly complete collection of the varieties of *Lilium elegans*, and samples of *Allium sphaerocephalum atro-purpureum*, newly introduced in 1888. The Zoological Garden of Rotterdam sent some flowering plants of *Cynoches Loddigesi*, *Cattleya nobilior*, *C. gigas*, and *C. Gaskeliana*.

SCIENTIFIC COMMITTEE, JUNE 27TH.—Messrs. E. H. Krelage and Son at Haarlem submitted to the Committee dormant bulbs of *Fritillaria*

persica. According to a communication of Mr. M. C. Parke, Stretton Hall, Leicester, some bulbs of a species of the *Fritillaria* had started growing again after being dormant for thirteen years. The Committee decided that some of these bulbs should be planted in the Botanical Garden at Amsterdam in order to ascertain how long their rest would last. The same firm sent a branch of *Maclura aurantiaca* which came from Hungary, where that shrub, originally from North America, endures the winter in the open air. Professor de Vries sent specimens of *Dipsacus sylvestris* with distorted stalks in the form of a spire, which abnormal growth had continued during three generations. With the above-named large numbers of plants and flowers with abnormal characteristics were also exhibited.

FLORAL COMMITTEE, SEPTEMBER 10TH.—First-class certificates were awarded to Messrs. E. H. Krelage & Son, Haarlem, for their new plants, *Crocus aurea imperialis* and *Nerine excellens* Moore. To Mr. J. J. Jansen, gardener to Mr. Beckeringh, Driebergen, for his new variety of *Anthurium* with a white spathe. To Mr. J. F. van den Berg, Jutfaas, for a collection of cut flowers of *Tuberous Begonias gigantea* and *gigantea duplex*. To Messrs. Zocher & Co., Haarlem, for a collection of *Tuberous Begonia* with single and double flowers, and to Mr. H. J. van Heyst, Wyk Cy. Duurstede, for an interesting collection of Ferns, grown in the open air. To Messrs. Groenewegen & Co., Amsterdam, for seven varieties of dwarf *Cannas* with large flowers. To Messrs. J. Mater and Son, Leyden, for some plants introduced from Japan.

Second-class certificates were awarded to Messrs. Groenewegen & Co., for four new varieties of *Cactus Dahlias* with gigantic flowers, and for *Chrysanthemum* Mrs. Burrell. To Messrs. E. H. Krelage & Son for a collection of cut flowers from bulbous and tuberous plants. The same firm sent a collection of cut flowers from varieties of *Montbretia* and *Kniphofia*, among which was *Kniphofia aloides grandiflora gigantea* (Krelage). In this collection were cut flowers of *Alstroemeria peruviana* Ostade (Krelage) remarkable for their dark reddish brown colour.

ORNAMENTAL PLANTS COMMITTEE.—A first-class certificate was awarded to Mr. K. Wezelenburg, Hazerswoude, for *Cupressus Lawsoniana filiformis glauca* (Wezelenburg). Second-class certificates were given to Mr. K. Wezelenburg, for the new *Cupressus Lawsoniana*, *Souvenir de Leide*. To Mr. A. M. C. Jongkindt Coninck, Dedemsvaart, for *Cupressus Lawsoniana robusta*, recently brought into the trade, and remarkable for its hardness.

FRUIT COMMITTEE.—A second-class certificate was given to Messrs. Boog & Crans, Elden, near Arnheim, for the Peach Antoinette. This variety is remarkable for its fertility and excellent fruits, and still more for its volume and beautiful colour.

SCIENTIFIC COMMITTEE.—The Botanical Garden of Amsterdam sent a *Reschorneria multiflora*, with a great number of young plants on the inflorescence.

Professor de Vries sent two specimens of *Zea Mais* totally infertile in two generations.

Messrs. Krelage & Son sent some seedling plants of *Agave filifera*, showing very different characters. It is not likely that they are hybrids, while there were no other in the neighbourhood that bore flowers at the same time.—H. C. ZWART, *Secretary*.

PEAR GROWING EXTRAORDINARY.

A WORD or two about one who has risen to some eminence as a grower may not be inopportune. We allude to Mr. James Butler, manager of Mr. A. J. Thomas's Nursery, Orchard Lane, Sittingbourne. The garden, about 4 acres in extent, was formerly a Cherry orchard—one of the oldest plantations in Kent—but it ceased to exist some twenty years ago, when the soil was excavated to a great depth for brick earth. Since then, by good management, the ground has again been brought under cultivation, and it is indeed a fruitful spot, every year seeing crops on the trees of the finest quality. The situation is low and well sheltered, and the soil is good, well-drained loam, resting on a subsoil varying from chalk to a good deep loam—principally the latter. The greater portion of the ground is enclosed by a substantial and lofty brick wall, against which are trained not far short of 200 Pear trees, principally as oblique cordons, the remainder being trained vertically. While Apple trees are studded here and there, the garden itself is principally devoted to the cultivation of Pears, trees of which stand in ranks over the whole place. Here, with a south-west aspect, and aided by extensive supplies of manure, Pears are grown to a high state of perfection. Not only is the fruit large and shapely and of the first quality, but it attains a superb colour; and it is, really, the combination of these qualities which has gained such fame for Mr. Butler's Pears. Over 140 varieties are now in cultivation here, and when the trees are at the height of maturity—although at the time of this visit it should be mentioned that some of the trees had been thinned of the earlier sorts—a unique sight is presented to view. One variety, *Beurré d'Amanlis*, was well represented. The branches were heavily laden with fruit; so much so, that props had to be largely resorted to. Louise Bonne of Jersey, one of the best quality, and on which there is a great run, is another sort largely cultivated at Orchard Lane—dwarf trees of about 4 feet or 5 feet in height, with branches spreading over an area of from 12 feet to 14 feet. Duchesse d'Angoulême next claimed attention. Mr. Butler said, "That's a very valuable dessert Pear, and one that I have been very successful with." Questioned a little further, he said, "Those Pears often fetch 4s. a dozen in the market." "And what quantity of that particular kind of Pear do you send to market during the season?"

"The seasons vary very much," answered our guide, "but I think that I have sent up nearly a thousand bushels during my best seasons." The Windsor, an August Pear, is here grown to perfection. At the time of our visit some of the best specimens were being reserved for exhibition purposes. One or two magnificent clusters caught the eye. There they were, carefully surrounded by a net to protect them from the wind, awaiting the moment when they would be gathered in order to be sent to the metropolis. Beurré Clairgeau, a handsome deep red Pear, shaded to an olive green, and a heavy cropper, is largely grown.

The next variety claiming notice is Pitmaston Duchess, and it is in the cultivation of this superb fruit that Mr. Butler excels. It is one of the best of our dessert Pear trees, and is grown on pyramid and bush trees, the last named reaching a height of from 6 feet to 7 feet. The Pitmaston is a rich mellow Pear of a deep yellow tinge when ripe, the season for which is October and November. It commands a good price in the market, and large quantities are sent from this garden to London, where they realise an average price of 4s. a dozen. The pyramids reach a greater height than the bush trees. While speaking of the Pitmaston Duchess, we found that for three years running Mr. Butler carried off the first prize offered for the six best specimens of Pitmaston Duchess at the Royal Horticultural Society's Show at South Kensington. These exhibitions have now ceased to be held. The specimens shown averaged 22 ozs. apiece. For three years in succession he has taken the first prize of £10 at the Crystal Palace hardy fruit Show in October for the best collection of Pears, staging nearly 100 varieties. "And," said our friend, with a merry twinkle in his eye, "I am going to try to win it this year." Madame Treyve is an immense cropper, and this could be well believed, for the trees of this variety were literally like so many ropes of Pears awaiting the hands of the gatherer. This is a Pear of fine flavour from September to October. Williams' Bon Chrétien is grown to a large size, and as sound as a bell. Doyenné Boussoch, Maréchal de Cour, Doyenné du Comice, Beurré Diel, Beurré Hardy, Brockworth Park, Beurré Bachelier, Durondeau, General Tottleben, Beurré de l'Assomption, Bergamotte d'Esperen, Josephine de Malines, Beurré Bosc, Princess, and hosts of other Pears are also in cultivation. As may be imagined, with such a choice, a large and varied collection for exhibition is easily obtainable.

Apples are not overlooked either. Many trees were well covered with choice fruit, among the leading varieties being Cox's Orange Pippin, Peasgood's Nonesuch, Cox's Pomona, Lord Suffield, Lord Grosvenor (a recent introduction, and similar to Lord Suffield, an Apple that will be better known in the future), The Queen, Worcester Pearmain, Stirling Castle, Lane's Prince Albert, Ecklinville Seedling, Tower of Glamis, and Wellington. These receive careful attention at the Orchard Lane Nursery, and, it is almost invidious to add, are made to produce all that it is possible for a tree to bear.—(*From the East Kent Gazette.*)

FRUIT FORCING.

VINES.—*Early Forced Vines in Pots.*—To have ripe Grapes in March or early April the Vines should not be started later than the early part of November. If bottom heat can be given to start them they will break well. Provided there is a bed of about 3 feet depth and 4 feet width the pots may be raised upon bricks in pillar fashion, so that their rims are slightly higher than the pit edge, and so that the pots will be in the centre of the bed. Leaves being placed in to fill the pit a gentle warmth will be afforded, and the Vine roots will pass into the leaves, deriving beneficial support. The temperature at the roots ought not to exceed 75°, and in the atmosphere 50° to 55° by artificial means, until the buds swell, then gradually increase it to 60° or 65° when they are breaking. The canes should be depressed to a horizontal position to secure their breaking regularly. Damp the house and canes in the morning and afternoon.

Early Forced Planted-out Vines.—Those to be forced to afford ripe Grapes in April should be started by the middle of November. It is not advisable to start permanently planted Vines so early where there is convenience for growing some in pots, as it is a great strain upon the plants to make their growth at the duldest period of the year and to rest at the hottest. The Vines, it is presumed, were pruned about the middle of September and the house kept cool and dry. Protect the outside borders from autumn rains by covering them before the ground is chilled. A good covering of dry leaves, with a little litter to prevent them blowing about, is effective, and if a tarpaulin is employed over all nothing further need be done. Where fermenting materials are available they are a great aid in forcing operations, and especially so for placing inside the house to maintain a genial condition of the atmosphere without recourse to so much fire heat or sprinklings from the syringe. The materials need not be used until the house is closed, but they must be thrown into a heap a week or ten days previously, turned and moistened if necessary. Three parts of Oak or Beech leaves to one of stable litter will give a more suitable warmth and ammonia vapour

than all dung. Mix the leaves well together when thrown into the heap, damping them if dry, turning them when they are getting warm, again damping if necessary, and when well warmed through they are fit for placing in the house.

Late Grapes.—If the Vines were hastened in spring by the aid of fire heat these will be thoroughly ripened, and it is much preferable maintaining a forcing temperature after October comes in to secure the ripening of the fruit. In the latter case the temperature must not be less than 70° to 75° by day and 65° at night, falling 5° through the night, allowing an advance to 80° or 85° from sun heat, continuing this until the Grapes are ripe, at least until the wood is brown and hard. The fruit being thoroughly ripe, in which state only can the Grapes be expected to winter satisfactorily, and the wood be thoroughly matured, all spray or laterals may be removed down to the main buds, ventilating freely on all favourable occasions. Fire heat will then only be necessary to prevent the temperature falling below 50°. To prevent dust settling upon the berries raking or sweeping must not be practised. Mats or clean dry straw laid over the inside borders will to some extent prevent evaporation, assist in keeping the atmosphere dry, and prevent the soil cracking. The outside borders must be covered if the fruit is to keep satisfactorily. Glass lights are best, wooden shutters good, and tarpaulin over dry bracken or straw answers well. A thick thatch of straw or bracken is very serviceable.

Young Vines.—Young Vines generally have a tendency to continue growing to a late period, which may be checked by stopping the shoots moderately, and facilitate the ripening of the wood by a high and dry atmosphere—i.e., a temperature of 70° to 75° by artificial means, and 80° to 85° with sun heat by day, shutting off the heat and keeping the ventilators open by night.

MELONS.—Be careful in the application of water, but the latest plants with fruit swelling must not be allowed to become dry at the roots. Keep up moderate moisture by damping every morning and at closing time, earthing the plants as required. Remove all superfluous growths as they appear, and maintain a temperature of 65° to 70° at night, 70° to 75° by day, up to 85° or 90° with sun heat. Keep the bottom heat at about 80°. Fruit ripening will be the better for a little extra fire heat and ventilation constantly; a dry state at the roots, but not so dry as to cause the leaves to flag, accelerates the ripening process. In dung-heated pits and frames no water will be required after this. Keep the frames well lined, admitting a little air constantly, which with the fruit raised well above the surface of the bed will do much to impart flavour. Any fruit it is wished to keep for a time must be cut when changing with a good portion of stem, and be kept in a dry airy room, or if wanted ripe at once they may be placed in a warm airy house in the full sun, and they ripen better than in frames or pits devoid of artificial heat.

CHERRIES.—If it is intended to plant any trees it should be seen to as soon as the leaves have fallen, or if the trees are at hand those trained to walls for four, or five, or six years are best, and if repeatedly lifted they may be planted as soon as the leaves give indications of falling. The Cherry, like all stone fruits, thrives best in a calcareous soil, turfy loam inclined to be strong rather than light, with a tenth of old mortar rubbish and a sixth of wood scrapings thoroughly incorporated answering well, the border being about 24 inches deep, over 9 inches to a foot of drainage, secured with a layer of old mortar rubbish, and about 6 feet wide, which is ample for trees grown under glass. Black Tartarian and May Duke are the best varieties, but Early Rivers is a welcome addition, and especially valuable for early dishes. The yellow fleshed varieties form an acceptable addition to the dessert when fresh fruit is not plentiful. Early Jaboulay, Elton, and Governor Wood are first-rate; the lights having been removed they need not be replaced for a month or six weeks, the old surface soil being removed without injury to the roots and fresh compost supplied, that above named answering with the addition of a fourth of manure.

Trees in pots to be shifted into a larger size should be attended to at once, and those not to be so treated should be turned out of the pots. Remove a few pinches of soil from the base, cut the roots back and supply fresh loam, adding about a tenth of old mortar rubbish and a sprinkling of half-inch bones with good drainage. Remove the surface soil, supplying the above compost, adding a fourth of decayed manure. Whether for trees planted out or in pots the soil should be made firm. Afford a good watering, and place the trees where they can have plenty of air. If outdoors they may be plunged over the rim of the pots.

THE FLOWER GARDEN.

Propagating Shrubby Calceolarias.—Where large numbers of bedding plants are required these Calceolarias ought to be extensively grown, and they are especially serviceable in places where the convenience for wintering tender plants is of a limited character. All they require is to be kept cool and protected from severe frosts, and they need never be placed in pots or in a heated house at any time. Cuttings ought to be inserted now or before they are damaged by severe frosts. The ordinary garden frames are best for striking and wintering the plants in. These should be placed in a convenient well drained position, raised from the ground with the aid of bricks at each corner, inside being placed a firm layer of half-decayed heating material, nothing being better than leaves and stable manure in equal parts, bringing up the 6 inches of fine loamy soil near to the glass. Face the latter with sharp sand or road grit, and make all firm and level. Select firm short-jointed flowerless tops of young shoots. Cut these to the third or fourth joint, trimming off the lower pair of leaves only, and dibble them in firmly

about 3 inches apart each way, and water through a moderately fine-rose pot. Put on the lights and shade from bright sunshine. When the cuttings are recovered somewhat a little air may be admitted, especially during warm nights; the shading also being gradually withheld. If the cuttings are unduly coddled they will grow and become weakly, whereas the aim should be to keep them dwarf and sturdy.

Violas, Pansies, and Gazanias.—The first named are a beautiful and serviceable class of bedding plants. Pansies are favourites everywhere; and the old-fashioned *Gazania splendens* is also effectively used in some summer bedding arrangements. All strike as readily and thrive under much the same treatment as that above recommended for *Calceolarias*. Young flowerless shoots springing from the centre of the plants of *Violas* and *Pansies* are the best for striking, but the older tops answer nearly as well. These may be taken 2 inches or rather more in length, trimmed to a joint, and dibbled in clear of each other all over the bed. Every cutting will usually strike root and make stocky little plants for transplanting to more roomy quarters next spring. The cuttings of *Gazanias* should be somewhat longer, and will require rather more protection during the winter.

Late Propagated Pelargoniums.—Where no very severe frosts have been experienced the Zonal *Pelargoniums* are unusually gay for the time of year. This is partly the result of the wood being short-jointed and firm, and as this is also the best for propagating purposes there is no reason why more cuttings should not be inserted if need be. In many places it is hardly possible to winter too many of these still popular summer bedding plants, and in any case it is always wise to have more cuttings than needed, a considerable number not unfrequently being lost during the winter. Only the firmest shoots ought to be made into cuttings, these being allowed to lie in the sunshine or light for several hours in order that much superfluous or dangerous sap may be evaporated. Place them rather thickly in small pots, set on shelves in cool houses near the glass, and give only sufficient water to prevent much shrivelling.

Preparing Sites for Bulbs.—Many of the commoner kinds and varieties will usually flower well for one season at any rate if planted in ground not specially prepared for them in any way. The soil in the flower beds is quite good enough for the ordinary bedding kinds, including *Hyacinths*, *Narcissi*, *Tulips*, *Snowdrops*, *Crocuses*, and *Scillas*, the greater portion of which are lifted prior to filling the beds with their summer occupants, and are seldom of much service afterwards. The choicer *Daffodils*, *Narcissi*, *Tulips*, *Anemones*, *Grape and Feather Hyacinths*, *Triteleias*, *Leucojums*, *Irises*, *Jonquils*, *Snowdrops*, *Aconites*, and *Crocuses* generally succeed, however, much the best when planted in well prepared sites, not being disturbed for five years or more. All delight in well manured, deeply dug or trenched ground, with abundance of fresh turfy compost disposed immediately about the bulbs. They will pay well for this treatment, and instead of flowering well the first season only will continue till eventually large clumps will be available for dividing and transplanting.

PLANT HOUSES.

Calceolarias.—To have plants that are rarely attacked by aphides, they must be repotted from time to time, as they need more root-room. If the plants are once neglected in this respect they soon become a prey to these pests. Now that frame room is more abundant we are placing all our largest plants into 6-inch pots, and later plants are being attended to in this respect according to the size they need. These plants will do well in cold frames for some time. They grow rapidly at this season when stood on a cool moist base. On no account remove them to greenhouses and arrange them on shelves or open lattice staging, as such positions are too dry.

Cinerarias.—These plants suffer from damp in cold frames in many localities if crowded thickly together. There is no difficulty in keeping them in these positions for at least another two months if they are arranged thinly so that plenty of air can play about the foliage. Damping occurs when their leaves are allowed to hang wet for several days in succession. The earliest plants producing their flower stems may have weak stimulants every time water is needed. Nothing is better for them than soot water in a clear state. The plants needed for spring flowering are now being placed into 5 and 6-inch pots, and later ones into 4-inch pots.

Primulas.—Plenty of the early plants are now showing flower, and will soon be suitable for decoration if placed indoors where the temperature does not fall below 45° to 50°. A few of these are useful after the third week of this month for associating with other plants in the conservatory, or even for room decoration. Repot all late plants that need it and are to be retained for spring flowering. Admit air liberally during fine days. These plants will be safe in cold frames until the end of the month. They will do afterwards on shelves, or in almost any position, provided they are kept cool. All late flowering plants should be grown as sturdily as possible, and then they will produce strong flower stems in profusion in spring. Keep double varieties in a house where the atmosphere is moderately dry and the temperature not allowed to fall below 50°. Water these with care; if first kept wet and then dry they are almost certain to decay at the "collar." Keep the soil as near an intermediate state of moisture as possible.

Abutilons.—If these are to continue growing and flowering throughout the autumn they must have a night temperature of 50° to 55°, with a day temperature 10° higher. When kept in a cool airy structure the flower buds that form soon turn yellow and fall. The flowers open by the aid of a little warmth, and will continue as long as the plants are growing slowly.

Cyclamens.—If a few plants are wanted in flower place them on a shelf near to the glass where the night temperature ranges from 50° to 55°, and their flowers will soon appear above the foliage. Do not hurry them or keep them in a close confined atmosphere, or the foliage as well as the flowers will be drawn up weakly. Those not required in flower will do for the present in cool houses. Give the plants weak liquid manure occasionally, and keep them near to the glass. If seed has not been sown for next year's supply do so at once. The seeds germinate quickly in a temperature of 60° to 65°, and they should be covered lightly with fine soil, with a square of glass over the pan or pot. After gradually expose the seedlings to light and a cooler temperature. Prick them out singly 1 inch apart into shallow pans or boxes. Do not allow them to become dry, and gradually harden them to an intermediate temperature.

Tea Roses.—If allowed to break into growth under cool treatment these may now have a position where careful ventilation can be provided, with a temperature that will not fall below 55°. Where flowers are wanted by Christmas no time should be lost in pruning the plants. Subject them to the coolest treatment, so that they will enjoy complete rest for a week or two before starting them again. Free the house of aphides before pruning, for they will prove a source of trouble when the foliage is tender. For flowering at Christmas *Safrano* and *Isabella Sprunt* are decidedly the two best. They grow freely and flower profusely.

Hybrid Perpetuals.—Where it is necessary to increase the stock of these pot some at once. If done while the foliage is fresh and plunged outside, the pots will be partially filled with roots before the approach of frost.

Eucharis amazonica.—If the supply of blooms from these is required over a long period during the autumn and winter, those that have completed their growth may be removed to cooler quarters for a few weeks to rest. Do not remove too many plants at one time; select a few of the most promising, and a few more at intervals of ten days or a fortnight according to the time they complete their growth. The rest they enjoy in cool quarters can either be of short or long duration according to circumstances. Those that have first flowered must be pushed into growth, and with good management should flower again in January. With care and judgment in pushing plants forward and retarding others there is no difficulty in having *Eucharises* during the whole of the year, though intervals of a week or fortnight may elapse without blooms even under the best of management, as it is very difficult to time the plants to a few days. Before the plants are removed to cooler quarters allow them to become somewhat drier at their roots, and keep them in this condition until they are returned to the stove. At the same time they must not be allowed to flag or suffer by an insufficient supply of water at their roots.

THE BEE-KEEPER

NOTES ON BEES.

YOUNG QUEENS.

WITHIN the past ten days numerous inquiries have come to hand as to whether I could supply a fertile queen or queens, as one or more of their stocks were either queenless or had virgin queens only. Through the kindness of acquaintances and the surplus from my own stock I have been able to supply a few, but many are still unserved. The dealers are not exhausted, and if those in want of such apply to them they will be supplied at a moderate rate. Although the current year has not been so disastrous as 1878 was many queens are this year unfertilised, especially those that superseded the queen regnant late in July and August. The want of sunshine during these months, but not a high temperature, was conducive to this. It is a good plan at this season for bee-keepers to preserve a few nuclei to replace defective queens either now or whenever drone brood appears out or inside the hive. I have preserved queens for weeks by caging and placing them between the combs amongst the bees. There is no safer plan than this, and the bee-keeper will be studying his own interest if, now they are cheap, he provides himself with a few queens, preserving them in the manner stated above.

INTRODUCING QUEENS.

It is a considerable time since I asked for information regarding the thirty minutes' starving process, what is new, or what is gained by the "Simmins" method of direct introduction, but the desired information has been withheld. My own opinion is, There is nothing new, nor is there anything gained by the method unless it be the thirty minutes' starving process. It is several years since I advised in these pages to keep the queen from eating other honey, than that belonging to the hive to which she was to be introduced,

and no time is gained over the caging system; indeed, there is a positive loss. Queens caged are regularly and sumptuously fed, which brings them into the laying state quicker and safer than the so-called direct method of introducing queens.

CARNIOLIAN QUEENS.

We have been frequently asked where these queens can be procured pure, owing to disappointment in getting cross-bred queens instead of pure ones. I have just received as handsome a Carniolian queen as I ever possessed, accompanied by some of her progeny, truly and purely marked, as a present from a bee-keeper in the West Highlands, who is fortunate in being in an isolated place, so that he will have no difficulty in rearing and supplying a large number of pure Carniolian queens to bee-keepers. I learn from him that he will not breed queens for sale other than in full strength stocks during June and July, so that nothing but queens of the first grade will be sent out. The bees and queen were four days on journey, and arrived in splendid condition although the weather was cold and frosty. His apiary is perhaps the largest in Scotland, comprising about 200 stocks of bees. His advertisement will appear in due course, and from my personal knowledge of him I am sure that nothing but reliable queens will be sent out.

SWARMS LEAVING THEIR OLD QUEEN.

Lately I mentioned a case where a swarm issued from a hive leaving the queen regnant behind and undisturbed owing to the queen that left with the swarm having been blown on to it from an adjoining hive being the second swarm that had issued from it. According to the rule that the old queen always leaves with the first swarm we should have looked for her in it, but when making an examination of this hive the imported queen of October, 1888, was still regnant, although from the absence of eggs during August, and a subsequent dissection proved, she had in a great measure become unfertile; simply another proof of the advisability of at least once in the year giving a young queen to every stock, and where the greatest results are wanted give two.

SWARMING.

Whatever many bee-keepers think, some of them write as if swarms issued from some sudden impulse, and not from any premeditated preparations. The impression is received, and becomes stereotyped on the minds of novices; then to prevent swarming they resort to the inventions of those who appear never to have studied the causes of swarming, hence come disappointments. I have frequently experienced bees being in a state of preparation to swarm for more than a month, stress of weather alone causing them to gnaw the queen cells, and so for a time preventing the swarm issuing. Sometimes the queen regnant was deposed, and a young queen took her place, sometimes with and sometimes without any after swarms, depending altogether upon the weather. The same thing occurs sometimes after the introduction of an alien queen. Queen cells are brought forward; if fine weather prevails the old or newly introduced queen is deposed, but if the weather proves unfavourable the royal cells are destroyed, and she is allowed to reign in peace.

It is indeed a rare thing to find a swarm issuing without making preparations beforehand, the usual time being between eight and ten days. The foregoing will enlighten those who may not have a clear conception of swarming, its causes and prevention.

ENEMIES.

Mice are now seeking for winter quarters, hives being a favourite resort, and bees and honey are food greatly relished. Guard against their inroads, and with a similar assiduity search for defects, and prevent rain passing into the interior of the hive.—A LANARKSHIRE BEE-KEEPER.

TRADE CATALOGUES RECEIVED.

- A. M. C. Jongkindt, Coninck, Dedemsvaart, Zwolle, Netherlands.—*Catalogue of Trees, Shrubs, &c.*
 R. Owen, Maidenhead.—*Pedigree Chrysanthemums.*
 L. Späth, Berlin.—*General Catalogue.*
 L. Delaville, 2, Quai de Méjissieric, Paris.—*List of Bulbs.*

* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Vines—Gladioluses—Chrysanthemums (W. B., F. J., and T. W.).—Your letters did not arrive soon enough to be satisfactorily answered this week.

Grapes for Cool House (M. C. B.).—If you have heat, both Buckland Sweetwater and Black Muscat (Muscat Hamburgh) would succeed; if unheated, Foster's Seedling and Trentham Black.

Six Roses (T. S.).—You give no indication as to the colours desired, nor whether you can wish to grow the plants indoors or out. The Bride, Marie Van Houtte, Madame de Watteville, Grace Darling, La France, and Général Jacqueminot give a long succession of flowers for cutting that have many admirers.

Young Men at Kew (Nemo).—There are many advantages to be gained by a little experience at Kew, especially if you should wish to obtain an appointment in any of the Colonial gardens. A wide knowledge of plants can be acquired there, and the system of culture is good in the chief departments. Applications are made to the Curator.

Burying Bulbs (F. J.).—We prefer cocoa-nut fibre refuse to any other material for the purpose, and it is cheap. We have seen both sawdust and ashes answer well, also fail, the former injuring the crowns where it contained much turpentine, the latter when it contained petroleum that had been thrown on the ashes after cleaning lamps. Good leaf soil answers the purpose in view very well.

Heaths and Epacris (J. W.).—You will find all the following useful free-growing and free-flowering Ericas—i.e., Cavendishiana, Ewcriana superba, gracilis autumnalis, hyemalis, perspicua nana, and Wilmoreana superba. Three good varieties of the E. ventricosa type are alba, magnifica, and tricolor. Epacris alba odorata, miniata splendens, and Vesuvius are useful free varieties likely to suit you.

Grapes not Colouring (D. Gardiner).—The crop is probably too heavy, and the root action defective. Your question was answered, but perhaps not in the number you obtained. Replies on gardening subjects are readily given to regular subscribers, but persons who only purchase a paper when they expect it to contain an answer to a question they have sent are quite likely to be disappointed. The remedy is obvious.

Propagating Ampelopsis (E. T. H.).—Firm portions of the young growths of A. Veitchi, cut in lengths of 5 or 6 inches and inserted deeply in sandy soil under handlights, at the present time emit roots. Many plants are raised by inserting cuttings closely together in pots, plunging these in frames for the winter, then placing in gentle heat in the spring. Several are grafted on stocks of the common Virginian Creeper, cuttings of which strike readily in the open ground.

Green Asparagus (M. C. B.).—It is sometimes difficult to distinguish any or but one variety of Asparagus, as we have found the colour depend greatly on the nature and texture of the soil. The Green-topped is considered the English and best flavoured variety, the Red-topped, or Dutch, the largest and most generally cultivated, indeed the sub-varieties of the latter have entirely superseded both. Perhaps the only plan of securing the Green-topped would be to save some seeds from plants that have the desired characteristic, and which may be found occasionally in old beds, and more frequently amongst seedlings of common Asparagus.

Insects on Strawberries (W. B.).—The leaves are infested with a small mite similar to the red spider, and only differing from it in hardness and colour. It is known as Acarus hortensis, and preys upon different kinds of plants. Being on the under sides of the young leaves, and protected to some extent by their hairs, its eradication must of necessity be tedious, unless the plants are in pots in preparation for forcing, in which case they can be easily dipped and swirled to and fro in a solution of soft soap, to which enough sulphur is added to render it of a thin creamy consistency. If the plants are in the ground many of the insects may be destroyed by one person bending the leaves over, and another applying the mixture forcibly through a syringe, or in any other better method that may be devised on the spot. Some varieties are more prone to the attacks of insects than others, and old or weak plants are more liable to be infested than are the young and more sturdy in growth.

Blotched Apples (*Constant Reader*).—The Apple you have sent is attacked by a fungus, but we are unable to state the cause of the attack, as you give us no information respecting the age or condition of the trees or the nature of the soil. The attacks are the most common where the trees are not well supported, the foliage lacking substance, hence unable to purify the crude sap. If the trees are old, and the soil dry, saturating the ground with strong liquid manure, after a plentiful supply of pure water, as has been recently advised, may be expected to improve them; if the subsoil is full of water draining is needed. Young trees can be improved by partially or wholly taking them up and surrounding the roots with loam containing an admixture of wood ashes and crushed mortar rubbish. With full root action in a suitable medium, and the growths sufficiently thin that the leaves are exposed to the direct action of the sun and air, the constitutions of the trees will be improved, and the fruit less liable to injury by fungoid attacks.

Manetti Stocks—Roses for Beds (*A. B. C. D.*).—Manetti stocks are raised from cuttings 9 inches long or more inserted slantingly and the soil drawn up to them in the form of ridges, only one or two buds being above ground, all below carefully cut out, or the Roses huddled on them would soon be overgrown by suckers. When buds are inserted the soil is levelled down for that purpose. Cuttings may be inserted now. You would probably find Roses on their own roots suitable for your purpose. Most of them strike freely from cuttings inserted now, but the lower buds need not be removed, as the growths from them often produce the most and finest blooms. In narrow beds 4 or 5 feet wide you may plant about 18 inches asunder, but you will soon find that some varieties grow much stronger and require more room than others. As you appear to be a novice in Rose culture you had better invest 1s. 1d. in Mr. Gilmour's "Rose Growing for Beginners," which can be had post free from this office for the price named. If after reading it carefully you need further information on any particular point write to us again.

The Nanny Apple (*E. Stephens*).—The name is a recognised one, and the variety is worth adding to your collection. The following is Dr. Hogg's description of this Apple in the "Fruit Manual." Fruit, medium sized, 2½ inches wide, 2½ inches high; roundish, narrowing towards the apex, and somewhat angular on the sides. Skin, smooth greenish yellow, with broken streaks of red, on the shaded side, but bright red, streaked with dark crimson, on the side next the sun; the whole strewn with russety dots. Eye, open, with divergent segments, placed in an angular basin, which is marked with linear marks of russet. Stamens, marginal; tube, long, conical. Stalk, short, inserted in a rather deep, round cavity, thickly lined with rough russet, which extends in ramifications over the base. Flesh, yellow, rather soft and tender, juicy, sugary, and highly flavoured. Cells, roundish ovate; axile, slit. A dessert Apple of excellent quality, and when in perfection a first rate fruit; it is in use during October, but soon becomes mealy. The tree attains the middle size and is a good bearer, much more so than the Ribston Pippin, to which the fruit bears some resemblance in flavour. This is met with about Havant and other districts in West Sussex, and on the borders of Hampshire.

Apple and Pear Trees Unfruitful (*S. G.*).—We have seen the stems of trees with longitudinal incisions through the bark down to the wood, which were made chiefly on trees the stems of which did not increase in thickness with the head, the descending sap current being obstructed at the junction of scion and stock, so as to cause a swelling or excrescence. The scoring of the bark was generally effectual in causing a thickening of the stem, as the injured part was promptly covered with new bark, and in that respect was beneficial in attaining the object of the incision—viz., an increase of supplies through the action of the absorbent and elaborating functions of the roots and leaves, and the tendency was to increase the health and vigour of the trees. Singularly we have known longitudinal incisions act oppositely on vigorous trees, the incision causing wounds which did not heal kindly, the growth being arrested, and a greater number of fruit buds followed. We do not, however, practise or recommend the procedure—viz., longitudinal incisions for vigorous trees. It may be useful when the stem is bark-bound, with a view to increased supplies of nutriment, but for trees that are too vigorous, "ringing" is a better plan, and one that is, if judiciously practised, safe and effectual. It consists in removing a ring of bark a quarter of an inch wide, the cuts being made down to the young wood or alburnum, and every particle of bark, inner and outer, removed between the cuts. It is as well to bear in mind that though ringing the stems or branches of trees tends to fruitfulness by checking the downward flow of the sap, causing the enlargement of the buds or the production of new fruit buds, it not unfrequently culminates in unsatisfactory crops after a few years.

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (*C. B.*).—1, Calville Blanche; 2, Alfriston; 3, Deme-low's Seedling; 4, Stirling Castle; Pear, Van Mons Leon Le Clerc. (*Mr. Wilbraham*).—2, Lady's Delight; 5, Gravenstein; 6, Lord Derby; the others we cannot identify. (*A. M. T.*).—1, Perhaps a highly coloured King of the Pippins; 2, probably a cider Apple; 3, Court Pendu Plat; 4, Louise Bonne of Jersey. (*A. C.*).—1, Fearn's Pippin; 2, Tom Putt; 3, Royal Somerset. (*E. J.*).—1, 3, and 5, Maréchal de Cour; 2, Gansel's

Bergamot; 4, Ne Plus Meuris; 6, Comte Lamy. (*H. J.*).—1, Swan's Egg; 2, Fondante d'Automne. (*J. A., Somerset*).—The Pear is Duchesse d'Angoulême; the Apple Blenheim Pippin, highly coloured. (*G. Taylor*).—We are unable to recognise with certainty any of the Apples, and suspect they are of local origin; they are generally inferior. (*G. L. Court*).—Sussex Forge Apple. (*Henry Mills*).—Golden Winter Pearmain. (*W. W.*).—The Apples are neither in a condition to be named nor worth naming; we did not think such trashy samples were still grown in Middlesex. (*J. E. P.*).—Cox's Pomona. (*E. Wallis*).—The Shropshire Damson. (*N. M.*).—The Fig is the Black Bourjassotte. (*H. H.*).—1, Marie Louise; 2, Lewis. (*L. T. K.*).—Dutch Codlin.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*H.*).—1, Physianthus albens; 2, Tritonia aurea; 3, Cupressus, perhaps C. torulosa, but habit not stated. (*W. C.*).—1 and 2, Davallia dissecta elegans; 3, Selaginella laevigata; 4, Hypericum calycinum; 5, Sedum spurium; 6, Davallia, specimen insufficient; 7, Centranthus ruber. (*Somerset*).—We cannot name your plant without seeing a specimen. Please send samples of the foliage and berries. (*J. J.*).—Clematis orientalis.

COVENT GARDEN MARKET.—OCTOBER 9TH.

Business quiet, with market well supplied.

LANDLORDS' FARMING.

LANDLORDS are certainly the victims of circumstances, for they have to submit to the inevitable, while if regarded in the same sense there need be nothing of the inevitable in a tenant's affairs. Mr. Clare Lewell Reed said recently, "The good land of this country is still worth a fair rent; the really bad, the very heavy, and the very light land is not worth farming without a rent. Take land which is in fair condition rather than take a farm that has been run out." This advice is sound and sensible, but it is after all mere class advice from a tenant farmer to tenant farmers, who if they are wise will turn it to account. We do not envy the feelings of a landlord with farms in hand and others falling in who reads it, for with him it is not a matter of choice, but of necessity. There is the land, what is he to do with it? We do not agree to suffer it to fall out of cultivation, we know he can do better than that, and as a landlord's agent we have paid dear for our knowledge.

It may be taken for granted that the majority of landlords are not practical farmers, and before all things they require an able steward at the helm to steer through the troubled waters of adversity with a fair prospect of success, and we are very confident a really efficient man would be quite content to work upon his merits, to farm by results, whatever might be the quality or condition of the land. We have shown that drainage and tillage are indispensable preliminaries, and are next brought face to face with the all-important question of cropping, for a crop we must have, and we shall not rest satisfied with anything short of a full one upon every part of the land. To grow ordinary farm crops to profit we must have mixed soil land of sound deep staple, and we need do little more than farm really well for the markets which we can serve to most advantage. With such soil success is a foregone conclusion, but it is with the extreme heavy and light and all soil of inferior grades that difficulties arise. To manage such land in an ordinary manner is to court failure. We must carefully consider each case, and treat it accordingly. Quite recently an agent who assumes charge of some heavy land farms this Michaelmas pronounced them unsuitable for the growth of Sainfoin. To convince him of his mistake he was shown many acres of this excellent forage plant all clothed with a full crop of the third year, and a large stack of Sainfoin hay of high quality. Now, this man had undertaken the management of difficult land without sufficient knowledge of the work before him, and assuredly the landlord will suffer in consequence.

For the moment the question pressing most upon us is, What winter crops can we grow to advantage? Beans and Peas are not desirable light land crops, but light land will under good management yield excellent crops of Trifolium incarnatum, winter Oats, Rye, Tares, and, dare we venture to add, Wheat? Yes, we have grown 40 bushels an acre of Wheat on such land by using chemical manures both in autumn and spring, also by sheep folding in autumn, followed by an early dressing of chemical manure in spring. There is really no good reason why moderately light land should not grow Wheat to profit if only it is kept well stored with manure. This must be our guiding principle—sustained fertility, as opposed to incipient exhaustion. It is all very well to say a certain field ought to bear another crop without manure, for it was "mucked" last year. The seed is sown accordingly, but the crop is never a full one because the land is in a state of incipient exhaustion at the sowing, and at the reaping it is practically exhausted of fertility. Economy—so called—leads to this result, but it is a mistake that is fatal to farming. Economic liberality is that which insures pro-

sperity; high farming, tempered by sound judgment, which avoids extravagant or fanciful expenditure, yet spends freely when the outlay points to profit.

If we decide to sow Wheat now, and the land is poor, manure must be drilled with the seed. For land that has been under thorough cultivation for some time the autumn dressing of manure should consist of bone flour and mineral superphosphate in equal parts, followed by another dressing in spring with the addition of nitrate of soda, and also muriate of potash if the land is deficient in potash. But for exhausted land the autumn dressing should consist of quarter cwt. steamed bone flour, quarter cwt. mineral superphosphate, and half cwt. nitrate of soda to insure vigorous growth from the first. Practical men whose words are not lightly spoken have told us again and again that the use of nitrogenous manures in autumn is wasteful and unnecessary, and we agree that it would be so for land which has been under their care, but we must have some soda in autumn for winter corn on farmed-out land. The spring dressing should consist of 1½ cwt. nitrate of soda, 1½ cwt. steamed bone flour, half cwt. mineral superphosphate, and half cwt. muriate of potash.

(To be continued.)

WORK ON THE HOME FARM.

Rye, winter Tares, and winter Oats are sown, so also is Wheat upon all fallow land, and winter Beans are being ploughed in expeditiously by using plough drills. When the soil crumbles freely before the plough, share the use of the plough drill is highly commendable, but if the land is sodden and turns over in the furrows without breaking up, the Beans are liable to perish beneath the inert mass of soil falling upon them as they are sown. Rather than incur this risk we would not sow at all, but wait and sow spring Beans. Much depends upon the exact condition of the soil, and it requires some experience to enable one to decide for the best when its condition is at all doubtful. Last autumn the bailiff of one of our off-hand farms, some twenty miles distant from the home farm, ventured to sow a thirty-acre field of Beans with the plough drills without consulting us. This is a clay farm, and so few plants grow owing to the compact state of the soil, that it had to be re-sown with Oats in spring. On another farm spring Beans were plough-drilled in this spring; the soil, though wet, was not quite so heavy, and when it became dry enough the surface was broken sufficiently with harrow to enable the plant to push freely through it, the result being a full crop of excellent Beans. Due care is taken to make enough water furrows to carry off surface water quickly from all ploughed or cropped land, and to finish the connection of every furrow with the ditches at once, as the work is in hand. Putting off such work to be done at leisure often leads to flooded corn and perished plants.

The nights grow cold and wet, and all cattle should be housed in clean, dry, comfortable yards with deep lodges affording perfect shelter. Calves are confined to sheds with small yards, and are well fed, a little extra care being taken to prevent any falling off in condition. Dairy cows must be kept from eating any falling leaves of an unpleasant flavour, or butter will be spoiled. Much harm is often done to horses by leaving them out too late in the year upon pasture. Not only should attention be given to the provision of shelter, but also to food, for horses now work hard, and they must have corn. An attack of swine fever at an upland farm has been checked by placing the affected animals apart in temporary shelters quite away from the yards, which remain unoccupied, all walls and fences having been dressed with a disinfectant, all litter and manure removed, the surface of the yard broken up and carted away, and fresh gravel laid down.

REMARKS.

29th.—Cloudy and cool.

30th.—Drizzle early, and frequent showers in afternoon and evening.

1st.—Frequent showers, but one or two specks of sunshine.

2nd.—Fine and generally bright.

3rd.—Showery early; wet from 11 A.M. to 1 P.M.; then fine with some sunshine.

4th.—Wet all day.

5th.—Bright morning, with one or two slight showers; wet afternoon and evening.

A wet and raw week, but with more sunshine than the numerical values suggest.

Temperature about 3° below the average.—G. J. SYMONS.

HARDY FRUIT AT EXHIBITIONS.

RECENT exhibitions of Apples and Pears, and especially the imposing display at the Crystal Palace last week, have forced a question to the front that appears to require the attention of exhibition authorities. For some time the practice has been steadily growing of including Apples and Pears which have been partially or wholly grown under glass in the collections exhibited, without indicating the method in which such splendid fruit has been produced. It is true the public are beginning to be informed in a negative way that the practice alluded to exists, by some such notification as that "all the fruit in this collection has been grown in the open ground." Over and over again at the Palace we were requested to direct attention to the artificial production of hardy fruit as a method of handicapping the produce of exhibitors who have neither the means nor the desire to resort to similar means of enlarging and improving the appearance of the specimens. No one condemned the practice of growing the fruit in the manner suggested, but only that of associating the dishes with others of samples grown in the open ground. We have also received letters on this subject, and in the whole of them we find almost identical expressions to the effect that the time has arrived for separate classes being provided for Apples and Pears grown under glass or in pots, also for those grown in a natural manner in the open ground.

Nor is the desire for a change on the lines indicated confined to gardeners and amateurs who have no orchard houses, but it is shared in by nurserymen who either have suitable glass structures at their disposal, or who could speedily erect them; but they do not consider it is the best way to place before the public varieties of hardy fruit grown with the aid of glass, which ninety-nine out of a hundred of the purchasers of trees must grow out of doors. They evidently suspect that present honours, won by extra aids, may lead to future disappointment; and there is the possibility of the public mind being impressed with the view that the splendid Apples seen at exhibitions, and which are really produced by garden or orchard trees, are grown under glass, and if that should come to pass they will not be encouraged to engage in the occupation of fruit culture.

For ordinary purposes of supply Apples and Pears must be grown in the customary way, or such improvements on it as experience suggests, so long as the principle is adhered to; and nothing can be more desirable than that the best examples and varieties grown on the same lines should be displayed where the public can inspect them, as they show what is within the reach of purchasers of trees if they are favourably situated, choose the best varieties, and bestow on them the best cultural attention. Exhibitions are then practically instructive, but if inexperienced visitors are tempted by the most handsome specimens which have been grown under glass, to order trees of the same varieties on the assumption that they can produce equally fine samples in their gardens, they will be misled, not instructed, by the shows, and no long time will elapse before the great expectations incited will end in disappointment.

The culture of Apples and Pears under glass, or partly under glass and partly in the open air, is a very delightful and, well conducted, a profitable occupation, because the magnificent specimens produced realise high or "fancy" prices for festival occasions,

when only the best is sought for regardless of cost; also for dressing the windows of high-class fruiterers' establishments; moreover, those who derive pleasure from growing hardy fruit, such as Apples and Pears in orchard houses, are equally justified in doing so, as are those who grow hardy flowers under glass, such as Hyacinths, Lilliums, Roses, and others which give so much satisfaction to their owners. About that there cannot be two opinions; but there is an unmistakeable feeling, deepening yearly, that orchard house fruit of the kinds under notice should be separately classed at public exhibitions of hardy fruit.

A distinguishing trait in the Anglo-Saxon character is not only the desire to excel but the determination to do so. It is this persistent endeavour that has enabled the race to assert its supremacy in production and colonisation. It is an admirable spirit, and it happily pervades the world of horticulture. If one competitor for supremacy adopts fresh methods by which he gains prominence others will inevitably follow; and if it is found in contests of hardy fruit that orchard houses give to their possessors an advantage, more and more of such artificially aided produce will be forthcoming, and the possibility is not very remote that the bulk of the dishes of Apples and Pears that are placed in competition for the leading prizes will consist of such fruit, which cannot be regarded as fairly representative of that grown in British gardens and orchards.

No one for a moment suggests that the inclusion of glass-aided Apples and Pears in collections of hardy fruit is done with the intention of leading visitors to suppose they can grow equally handsome specimens if they purchase trees and plant them in their gardens. Nothing of the kind is intended by the exhibitors. The object of each is to provide the most effective display. Exhibitors think much less about the public than of their fellow competitors when preparing for shows; but it must never be forgotten that the public are influenced by the exhibits, and it cannot answer in the end for them to be misled by lack of knowledge simply through the method in which one grower feels compelled to meet another in arranging his products for the approval of judges who award the prizes for the best examples. These gentlemen cannot take cognisance of the conditions under which fruit is grown, but must follow the schedules in making their awards, and until a distinction is made in them between glass-aided and garden-grown fruit the honours must inevitably fall to the best regardless of methods of production.

One of the most satisfactory thoughts that arise in the consideration of this question is the absolute non-necessity of glass-aided Apples for representing a high standard of excellence. No better fruit could be desired than that represented in hundreds of dishes at the Palace Show, as gathered from trees in gardens. As produce for supplying the markets it could hold its own with the best from orchards in other lands, and every year proves more conclusively than the past that the lost supremacy of British growers of hardy fruit is only temporary, and the time is approaching when it will be regained. The advance that has been made during the past few years, and particularly since the great Apple Congress at Chiswick in 1883, is both gratifying and encouraging; and there is not the slightest reason to suppose there will be any cessation of endeavour now that substantial agencies are established for the attainment of the object in view.

A division of classes which is now called for would be satisfactory to the majority of cultivators; growers of fruit would be placed on a greater equality at exhibitions, and the public would have fairer representative collections placed before them as standards of excellence not beyond their attainment in the outdoor section; while connoisseurs would see the advance in superiority of that resulting from extra appliances, and it is not unlikely that an impetus would be given to both forms of cultivation. Be that as it may, the present mixed method of exhibiting Apples and Pears is very far from meeting with general approval, and the whole

question appears to merit serious consideration with the view to the proposed change, which many hope for, being carried out.

PELARGONIUMS.

THOSE who grow for the market certainly produce Pelargoniums of the Show and Fancy type in fine condition ; but this is not the case in private gardening establishments. Feeble specimens are too frequently seen, yet when well grown their decorative value is unquestionable. If we judge rightly from the quantities of old plants cut back year after year that make growths very little thicker than a straw, we may conclude there is some reluctance in attempting to propagate fresh stock. Even if this course is decided upon it is difficult to obtain cuttings from those that make weak spindling flowering shoots only. Cuttings produced by such plants rarely form luxuriant specimens. No doubt the treatment they receive after they are pruned and started into growth may largely account for the unsatisfactory condition in which they are often seen. From some even of this description fresh vigorous stock might be raised if early spring propagation was adopted, but when the plants have to be flowered cuttings cannot be spared without disfiguring them. It would be wise in many cases to forego flowers for a season in preference to retaining worn-out stock.

Cultivators no doubt find a difficulty in propagating these as freely as Zonals, and the usual practice is to defer doing so until after the plants have flowered, and then insert what is little better than flower stems. Robust growers produce cuttings plentifully after flowering, but the plan is to secure as early as possible any non-flowering shoots that may be produced. When cut-back plants are grown there is no difficulty in selecting shoots for cuttings. Those grown for flowering during August and September yield cuttings plentifully, because they can be safely topped in early spring.

When Pelargoniums have to flower early in the year cuttings must be rooted early, and for this purpose it is useless to rely upon those from plants which flower during June and July. There is not time to root cuttings from these and grow them into creditable specimens by the end of September. Pelargoniums to flower early should by that time be strong and furnished with four to six good shoots. Do not pinch the shoots after the end of August, and then they will break strongly into growth and be in the best possible condition for their winter quarters. In this condition they are certain to flower early if properly treated. We fail to see why they cannot be had in flower much earlier in the year than is generally the case, even with the treatment accorded to Zonals during the early months of the year. At the present time the season is not so extended as it might be. Care and forethought only are necessary where glass accommodation is ample to flower them nine months out of the twelve.

The reason why cuttings do not strike freely is because those too soft or too hard are often inserted. The former if kept close and moist are liable to damp, while if kept dry they shrivel and are as long in rooting as those that have become too firm and ripe before insertion. This is the case even in spring, when unsuitable cuttings are selected. Sturdy cuttings that are kept moist after insertion can be rooted and often grown into plants a foot or more through by the time hard cuttings, or those that are rendered so by being kept dry, are induced to form roots. Good cuttings root freely enough during March in a temperature of 65° provided the soil is kept as near an intermediate state for moisture as possible. They certainly take a little longer to root than Zonals, but if treated the same as regards moisture in spring there would be no occasion to complain of the results. Cuttings inserted after the plants flower are frequently too firm, and consequently are a long time in rooting ; in fact, they made very little growth in the dull days of autumn. To induce them to grow then or during the winter results in weak spindling shoots. I am certain that if more moisture was given to the cuttings and less drying greater success would follow. Cuttings inserted after the middle of June strike better when dibbled into a border outside than they do when placed in pots in a frame. If dry weather follows insertion keep the cuttings moderately moist by syringing them once or twice daily.

Free flowering early varieties that are rooted in spring and induced to grow sturdily under glass until May in 4-inch pots will be furnished with three or four shoots. These should then be placed in 6-inch pots and grown in cold frames. When well established and the shoots have made three or four leaves they should be pinched again. If abundance of air is admitted they will grow strongly and branch freely. By the beginning of August they can be placed in 8-inch pots, and before the end of the

month they will be fully a foot through. These can be stopped again about the end of the month, and allowed to grow and flower. For the early months of the year they are better in 6 or 7-inch pots, and should have by the first week in September shoots after pinching about 1 inch long. Pinching in this case must be done early in August. After the end of September it is important that the plant have a light airy structure and a position near to the glass. Keep them growing slowly until the flower trusses are visible, when a temperature of 55° to 60° will bring them into flower. The atmosphere must be kept rather dry, air admitted freely on all favourable occasions, and water supplied with great care.

When cuttings are rooted from March until July there is no difficulty in having sturdy plants before the approach of winter. This is important, then the plants only need to grow slowly during the months of November, December, and January. All that is needed is to keep them in a moderately dry atmosphere, rather dry at their roots, and in a temperature that does not fall below 40°. They are, however, perfectly safe if frost only is excluded. In a very low temperature, however, the foliage is liable to suffer from damp. Plants that have their shoots stopped at the beginning of November break again into growth, and are in capital condition for placing in their largest pots in January. All shoots needing pinching must be attended to during the months when growth is practically at a standstill. It is only a waste of time to allow them to make more than four good joints before the points are removed. If this is done and the plants are close to the glass they will make sturdy growth as soon as the days lengthen, and will be capable of supporting their flowers without the aid of stakes. When they grow during the winter the shoots are soft and long-jointed ; in fact, they seldom, however good the treatment may be afterwards, make growth sufficiently firm and compact to flower as profusely as might be desired.

The sturdy compact appearance of plants, and the manner in which they flower, is largely due to the compost and the method of potting. If they are potted loosely and in an open compost they make soft growth, long-jointed wood, and flabby foliage. A little leaf mould, amounting to one-third, may be used with advantage at first, but afterwards none should be used. The most suitable compost is fibry loam, sand, and one-seventh of manure, which must be pressed firmly into the pots.

After the first flower trusses are visible soot water in a clear state assists them wonderfully, and artificial manures, such as Clay's, Beeson's, Standen's, or any other suitable kind, can be applied to the surface soil about once a fortnight. When liquid manures only are supplied the roots have a tendency to go downwards instead of coming to the surface.

Healthy Pelargoniums are seldom attacked by aphides to the same extent as those of weak growth, which are induced to make growth in winter in a close atmosphere. Plants of this description are difficult to deal with when once they are infested, simply because dipping in a solution of tobacco water, if strong enough to kill the insects, turns the leaves yellow, and the same results follow fumigating with tobacco. If done carefully healthy plants with leathery foliage will bear either treatment without injury.—NORTHERNER.

ARTICHOKES.

HELIANTHUS TUBEROSUS, or, as it is more generally known, the Jerusalem Artichoke, is a native of South America, and is quite hardy in this country. Why it received the name of Jerusalem is doubtful, very probably from its Italian name Girasole. It is of easy culture, as it thrives in almost any soil ; a rich, loamy soil, however, will be found to suit it best. No manure should be given, as this tends to promote a too-luxuriant foliage rather than the production of large and well-flavoured tubers.

The tubers for planting should be of a medium size, cutting any large ones in half and using as single sets ; these should be planted in rows 1 yard apart and from 10 to 12 inches between the sets, planting them about 4 inches deep. In many gardens these are met with in out-of-the-way corners, the excuse being given that the young tubers persist in growing after having once occupied a certain piece of ground. These, however, can be readily uprooted, hence there is no sufficient cause why they should not receive the good culture they certainly deserve.

The ripening stalks must not be cut down too early in the autumn, as it is during this ripening process that the tubers attain their full size, which would not be the case were they deprived of them prematurely. It is also not advisable to dig up and store the tubers, as by doing so they lose their natural freshness.

Cynara Scolymus, or the Globe Artichoke, is entirely different from the Jerusalem Artichoke ; this being a perennial plant from the south of Europe, and is without doubt cultivated more as a

luxury than for profit, the flower heads containing the edible part. It can be propagated by seeds or offsets. If by seeds they should be sown during the month of April upon an open, sunny site, these to be thinned out where too thick and transplanted the following spring to form permanent beds, planting them in rows 3 feet apart each way.

If increased by offsets remove some of the strong side growths from the parent plant during April or May, transplanting them as advised for seedlings. The flower heads are fit for use when they shew symptoms of opening, so as to show the florets within. When the object in view is to have large flower heads, the greater part of the small ones which issue from the sides should be pinched off. It is very important that when the flower heads are cut off that the flower stalk should be broken close to the ground, as when these are left they exhaust the roots. The heads can be kept for a short time in a cool place.

As winter approaches the plants should have some of the old leaves removed and be given a covering over the roots of manure litter, which must be removed the following spring. Then select four or five of the strongest shoots on each plant, removing all the others; this can be done by cutting them out with a spade, giving the plants afterwards a layer of manure and turning the soil to its former place, using the finest to go between and around each shoot retained.—A. G. FRAMPTON.

DRESSING ROSE BLOOM.

As this is a matter which has been much spoken of during the present season, and which is not unlikely to come on for adjudication before the highest Rosarian Court of Appeal, it may be well if you allow the subject ventilation in your columns.

The question at once occurs, What is "dressing?" What it is in the case of Chrysanthemums and Carnations is not unknown, and may be necessary, but is the queen of flowers to condescend to curl papers? As the late Sir Roger de Coverley used frequently to remark, there is "something to be said on both sides." It is certainly lawful to remove a damaged petal from an otherwise perfect bloom. As has been wittily observed, this is rather undressing! If a Rose has been arrested by some caprice of weather, and has not the perfect arrangement of petal which Nature intended, if some tender touches of an ivory pencil case will help it to what the "N. R. S." calls "the most perfect phase of its possible beauty," why, let it have it. But when it comes to dragging Marie Baumann into a distorted imitation of the Camellia roundness of A. K. Williams, or torturing Alfred Colomb into the solid stiffness of that best of travellers, Star of Waltham, it is quite another thing. A judge of high standing has told me of a box of twelve hedizened overdressed huzzies which he and his fellows sadly passed by as partaking more of the demi-monde than the beau monde of the Rose parterre. Thus perhaps the thing will right itself. If otherwise, alas! for the future. As Jane Taylor remarks in her moral poems somewhere with a slight adaptation,

I'd be the meanest thing that blows,
Rather than that affected Rose!
Its very scent offends my nose;
'Tis worse than any weed!

—A. C.

THE BRITISH FRUIT GROWERS' ASSOCIATION.

THE above Association held a meeting and Conference in the Entertainment Court at the Crystal Palace on Thursday last, October 10th, when about 200 persons were present, including the following amongst others:—Messrs. T. Francis Rivers, Sawbridgeworth; J. Austen, Witley Gardens, Stourport; Albert Bath, Sevenoaks; C. F. Barker, Hereford; T. W. Beach, Brentford; G. Bunyard, Maidstone; A. F. Barron, Chiswick; E. Butts, Streatham; J. Cheal, Crawley; J. Cranston, Hereford; G. W. Cummins, Carshalton; A. Dean, Bedford; G. Gordon, Gunnersbury; G. Hammond, Brentwood; J. Hudson, Acton; G. Merritt, Harpenden; C. Orchard, Isle of Wight; W. Roupell, Roupell Park; R. Smith, Yalding; J. C. Slater, Exeter; J. Wright, B. Wynne, and the Hon. Secretaries, Mr. Lewis Castle and W. Earley.

The President, Lord Brooke, M.P., had telegraphed regretting his inability to attend the meeting, and in his absence Mr. T. Francis Rivers, one of the Vice-Presidents, took the chair, opening the proceedings with an address, which is given in full at the end of these notes. Mr. J. Wright next read a paper devoted to a review of the Fruit Question. This evoked considerable discussion, in the course of which Mr. C. F. Barker stated that he believed the reason that England had fallen so enormously in the growth of hardy fruits was the English land laws. He was confident from the observations he had made during the last two or three years he had been resident in England, that were the

land laws as free as in the Australian colonies and in America English fruit growing would never have occupied the position it did now. The tenant farmer could not afford to grow trees because the tenancy of his land was so uncertain. Unless some drastic measures were taken to alter the relations between landlord and tenant they would only carry on a miserable existence in competing in fruit growing with America and Australia. Mr. Albert Bath stated that although the soil in Kent was so well adapted for fruit culture, he had found in recent travels that many other districts were quite as suitable, both as regards soil and situation. He called attention, however, to the dreadful ravages committed by the caterpillars of the winter moth, and he said it was one of the difficulties that must be met and overcome before success could be expected.

Mr. A. Dean remarked that at the present time the tenants could practically secure their own terms with regard to the land, and he believed there was not half a dozen landlords who would not let their land on favourable terms for the purposes of fruit culture. He suggested that something should be done in the way of setting up pomological schools in various parts of the country, and conducted by professors who might take students and teach them the pomology adapted to the requirements of particular districts.

Mr. G. Hammond also referred to the damage caused by caterpillars, as from nine acres of fruit trees this year he had only been able to gather about nine bushels of fruit from that cause. Trees had in some cases been completely stripped of the leaves, and he had seen similar instances elsewhere. In some subsequent discussion it was mentioned that Mr. Llewelyn of Penllergare employs a lamp suspended on the trees as a trap for moths, but it was explained that this would be useless in the case of that named, as the female moth does not fly.

Mr. G. Gordon read a practical paper on Peach Culture out of Doors, and Mr. Hudson supported the views he thereenunciated. Mr. R. Smith read a short paper on Apple Culture, and after some further discussion the Chairman moved—"That this meeting pass a resolution thanking the Lord Mayor and the Fruiterers' Company for the prominent part they have taken in encouraging the fruit growers of this country in advocating and recommending the cultivation of fruit on small holdings, and that such resolution should be conveyed to the Company, with an expression of willingness that this Association should assist as far as lies in its power in that good work."

Mr. Wright, in seconding the resolution, said the Fruiterers' Company had shown a desire to rise to the position of things, and though they might fairly believe that they were lacking in practical knowledge of fruit culture from the very necessity of their lives and their engagements, they had at least shown a real desire to do what they could and give information that would be of assistance to the small cultivators of fruit in the kingdom.

The resolution was put and carried.

On the motion of Mr. Bunyard, Maidstone, a vote of thanks was passed to those who had contributed papers; and a like compliment having, on the motion of Mr. Cheal, been paid to Mr. Rivers for presiding, the Conference was brought to a close.

AN ADDRESS BY MR. T. FRANCIS RIVERS.

SINCE we last met there are indications that public attention has been drawn to the very great importance of the meeting here last year, which was held for the purpose of pointing out the absolute necessity of developing fruit culture in these islands for the purpose of meeting the threatened competition from other countries with fruit of our own growing. Although we succeeded almost beyond our hopes in arousing the attention of cultivators and owners of land to the knowledge that we were not sufficiently awake to the fact of the enormous and increasing consumption of fruit, and that we were not making due preparation to meet this, either in the present or the future, as we are not content to rest satisfied with the success of that meeting, we have assembled again to-day to discuss the same subject, and to impress upon fruit growers the importance of the subject by repetition, and to elicit greater and more extended knowledge by discussion.

Fruit-growing has, I am glad to say, received very great assistance from the powerful advocacy of the Lord Mayor for the present year. For the first time I think in the civic history of London the chief magistrate has consented to depart from the traditions of commerce only, and has encouraged the cultivators of land in the United Kingdom to hope that they may derive some part of the profit which has been enjoyed to a very great extent by foreign cultivators, subject, of course, to the considerable deductions which they have to make over to English importers. London alone, with its millions of inhabitants, is an immense consumer, and it is difficult to say where it will stop, as there are no apparent signs of any cessation of building, turn to which side you will. With greater or more diffused wealth the demand for fruit will increase; it is a business which cannot fail except for physical reasons, such as the divergence of the Gulf Stream, which would probably have the effect of locking up our land in perpetual ice and snow, or the encroachment of ice from the North Pole, neither of which catastrophes seem at all likely to occur in our time. Foreign invasion

we hope that we shall know how to avert. The almost absolute certainty of continuance must be set against the fact that it is not possible to make a rapid fortune by growing fruit; it is not, however, subject to the vicissitudes which beset those who endeavour to achieve rapid fortunes; and although excessive foreign importations may to a certain extent check our legitimate hopes, the fruit-growing industry is not alone in this matter.

Our Society will, I hope, set before the public that fruit-growing should be more developed on farms, that it should not be confined to market gardens and to speculative orchards. If the multitude of farms were to devote a small proportion of land, say 1 rood to 150 acres—to the cultivation of fruit which is adapted to the soil, a very large supply would come to the markets. But I do not mean by naming this proportion of land that it is to be cultivated in the ordinary style of farm orchards, which seem to me always to promise a very remote profit to the planter, as so much time is consumed before the trees come into bearing, but an orchard fenced and cultivated as carefully as a well tended kitchen garden, the profit of such an orchard being amply sufficient to repay the care and labour given to it; by the production of fruit of superior size and quality, such as will be inevitably exacted by the consumer of the immediate future, who will not be content unless he is supplied with fruit of good quality either for the dessert or the kitchen. This quality can only be obtained by proper cultivation and the knowledge of soil and of classes of fruits adapted to the soil. As a rule I think too much reliance has been placed upon our venerable orchards. It has been, I think, too much the custom to consider that the inheritance of an orchard planted by a great grandfather is enough for the great grandson during his lifetime, and to this idea our present failure to meet foreign competition is in some measure due. These venerable trees are picturesque, but they are not profitable. A great part of the fruit when gathered is of inferior size, and has to be selected very carefully, generally leaving too large percentage of small fruits to realise a good price; and it is also very expensive to gather, as this cannot be done without ladders. The system of cultivation which I should advise, rightly or wrongly, is that of comparatively dwarf trees from which the fruit can be easily gathered, that they should be planted at distances varying from 6 to 9 feet, and that moderate pruning should be employed by which the trees can be kept at a size which will enable the planters to realise these conditions of gathering a large quantity of fruit from a limited area. You will soon perceive, on taking the measurement of a standard tree of fifteen or twenty years, that a great deal of room is occupied by unproductive wood, the stem and the branches spreading over a great space of ground, and not by any means improving the grass underneath. This waste is avoided by closer planting and more thorough cultivation. If it is supposed that such a plantation will not endure so long as our respectable old trees, it will at all events have fed and profited the planter, who need not trouble himself to look beyond his own necessities and desires. It is out of the question to think that fruit trees are to last so long that two or three generations are to elapse before new plantations are requisite.

At the risk of being thought too confident I must insist that the orchard of the present should be prepared by trenching 24 inches deep, with a very liberal supply of manure, fenced in with wire netting where game is plentiful, kept free from weeds, and planted with dwarf trees from 6 to 9 feet apart, a row of bush fruit planted between. Of orchard fruit in England the Apple and the Plum must always remain the most important, and in both classes the English can challenge the whole world for unrivalled excellence in sorts. At the present time we can, therefore, meet foreign competition by keeping our markets supplied with superior quality, and this we can do. Our Gooseberries, Currants, Strawberries, and Raspberries are better than any that the Continent can furnish, and although I believe that Continental growers are preparing to meet us by adopting our varieties, yet they cannot, in Gooseberries and Raspberries especially, compete against our climate, which is admirably suited to the production of these fruits.

It has been the custom for many centuries to consider the Crab stock as the only stock for Apples, except, of course, in gardens, and this is certainly true with regard to standard orchard trees; but as I have stated, and as I believe, that profitable Apple culture must be carried on by closer planting, it will be more advantageous to the planter to select a stock which has the property of inducing early fertility. There is no doubt that Apples grafted on the Crab stock will, if planted when two years old, come into bearing very quickly, but in the course of a few years the trees become too vigorous and produce more wood than is requisite. We have for some years employed the so-called Paradise

stock to correct this tendency with the best results. There is now a variety of stock produced from the seed of the Nonesuch Apple, and which is singularly well adapted for dwarf orchards. The trees are moderately vigorous, remarkably fertile, and, moreover, the production of roots is so profuse that trees seven or eight years old can be removed with safety; in fact I removed some hush trees of the Cox's Orange Pippin, which had been planted by my father, which have remained in the same place for fourteen years without root-pruning. These trees are still healthy fruit-bearing bushes, and are about twenty-four years old. This stock is the Nonesuch. The French Paradise, or the dwarf Apple of Armenia, is not at all suitable for planting for profit. Apples grafted upon it form pretty and curious garden trees, and nothing more. When I had the honour of reading a paper before you last year I mentioned a list of sorts, which was supplemented by other speakers, there is therefore no necessity to recapitulate these sorts. I may say that I hope before long our markets will be so well supplied with Apples of such good quality that our very good friends, the Americans, will be compelled to consume their flat, tasteless, and woolly Baldwins amongst themselves; we shall not want them here.

We are, I understand, menaced with the importation of Plums from the vast Plum-growing districts of Servia and Eastern Europe, probably the same sort of rubbish as that poured into Hull from the Plum orchards of Germany. The Servians, I understand, distil an ardent and fiery spirit from the Plum, horribly injurious to the consumer. This competition we shall have to meet. It seems to me almost incredible that the products of such a distance can beat us who are close to our markets; but here again the quality of the fruit must be the point on which we shall gain the day, and I am sure that we have the advantage of the choice of sorts, in Plums especially, and the quality, combined with quantity, must be our *Cheval de Bataille*. Let the Servians keep their own fruit, unless, indeed, we cannot beat them. In a former paper I have given my own experience of the most profitable sorts of Plums, to which I hope you will allow me to refer you. I have been successful in securing crops of Plums owing entirely to the quality of the soil, which is singularly favourable to their culture. It is a strong calcareous clay, and to the nature of the soil I owe all my success. The planter of Plum orchards should be very careful to examine the soil before making any large plantations. The Plum is one of the most valuable fruits for preserving and drying. Although dried Plums seem at present almost a continental monopoly, there is no reason why this industry should not be acclimatised in England, especially as I have reason to think that we shall find sorts of English Plums fully equal in drying properties to the most approved continental kinds. This is a matter which no doubt will be taken up and developed by our fruit preservers as soon as they are satisfied that the manufacture can be carried on with success and profit.

It is not only in England that the revival of fruit culture has awakened a strong interest. In Ireland efforts are being made to popularise the culture on small holdings. Mr. Bullock Hall, one of the leaders in this most important and salutary undertaking, has already published an account of the success that is likely to be derived from an intelligent system of cultivation.

All Englishmen will, I am sure, earnestly hope that Mr. Hall's efforts in this direction will be rewarded by the success which is due to him. I must here remind English growers that to Ireland we owe two of our most popular Apples, the Irish Peach and the Kerry Pippin. I think also that many varieties are peculiar to Ireland which are not found in this country. Besides the cultivation of the Apple I am sure that in Ireland districts can be found where Pears can be grown fully equal to those produced in the most favoured Pear country—namely, the south-west of France. From Limerick and its neighbourhood I have seen splendid specimens of Pears. If the necessary capital could be obtained I am convinced that a large Pear-growing industry could be established in certain parts of the south of Ireland, and Pears could be grown not only for the ordinary market, but of a size large enough to appear on the dessert tables of the wealthy. Of course it must be understood that the cultivation of large and weighty dessert fruit must be conducted under certain conditions—that is, on dwarf trees and in sheltered places, as they are too heavy to hang in gusty weather when they have attained their full size. As the season of dessert Pears lasts from September to March, and sorts exist which will furnish dessert tables during these months, it seems to me that a wide field is open, and that an opportunity is afforded which can be almost monopolised by Ireland.

Pear-growing in England is a very uncertain business. There are, no doubt, some localities in which the Pear orchard is profitable. I

have noticed that in the suburban gardens of London the Pear tree is generally more vigorous and healthy than the Apple, owing, no doubt, to the warmer climate and its capability of resisting the evil effects of the London smoke.

I observe that it has been remarked that the workman does not care about fruit. The cause of this indifference is not far to seek. A workman's bodily strength is his capital, and this capital must be carefully husbanded.

At present prices half a dozen Apples fit to eat would certainly cost 3d. I do not think the most ardent vegetarian would maintain that these Apples would satisfy a hungry appetite. Bread and cheese and an Onion would give more nourishment at the same cost. If fruit could be purchased cheaply enough for his income, I have no doubt the workman, if he did not care about it himself, would be glad to supply his children with this very necessary diet for young stomachs. This desirable result will no doubt arrive as soon as the orchards with which every suitable farm should be furnished come into working order, and the fact generally recognised that this replanting must be done. The remarkable influence which Mr. Gladstone so justly exercises on social matters in England when directed to fruit-growing has given an impetus which will not cease, and his speeches on behalf of fruit-growers in the past two years will be never forgotten. The Fruiterers' Company, departing from its traditional custom, which I think was connected solely with the importation of foreign fruit, has, with the assistance of the Lord Mayor, taken a great step in the encouragement of a native industry; and if the frosts of our English springs will abstain from destroying the tender blossoms of our fruits for a few years we shall establish such a supply that foreign competition will be compelled to cease from troubling us.

THE FRUIT QUESTION.

[Read by Mr. J. Wright at the Crystal Palace.]

WHEN requested to lend a helping hand in the promotion of any worthy object in the world of horticulture I am not able to give a refusal, but must try and do a little good in my day and generation. In these days of wide world competition there is great need for mutual help and friendly co-operation for the attainment of a common object of national importance—improving the food resources of the kingdom in the interests of every class in it—owners of land that has been falling in value of late; tillers of the ground who have had such slight returns for their labour, and consumers of the produce of the soil in placing before them better samples for their sustenance and enjoyment. That is the triune object in which many can aid, and by each doing a little it will be attained. But in the name of common sense let all petty jealousies be abandoned, and let us take a lesson from our rivals in other lands in working unitedly for the general good. This is entirely compatible with individual enterprise which is not in the slightest degree handicapped by association on a broad basis, and I am convinced that nothing but good can result from a policy of federation in furtherance of the important work of developing the resources of the nation to which we are proud to belong.

The object of the British Fruit Growers' Association is to promote the extension of fruit culture, to increase the quantity and improve the quality of home-grown fruit. "A very good object no doubt," observed a friend, with a cynical twinkle of the eye, "but don't you think nurserymen are at the bottom of it?" "Yes, certainly I do; and if you reflect for a moment you will find that there can be no substantial progress made without them. They are at the bottom of fruit culture just as iron is at the bottom of railways, and coal at the bottom of iron." Here you see is where the obstructiveness of suspicion and petty jealousy comes in. But depend upon it if my friend had had to dig his own coal, and wheel it home in his own barrow, he would not be half so well off as he is to-day. Whatever of prosperity has been enjoyed by the ironmaster and coalminer has not been obtained at the sacrifice of a single advantage that this user of their products possesses, but he has benefited by the use of that which has been provided for him better and cheaper than he could have obtained the necessities for himself. The benefits have been mutual. It is the same in the fruit tree world. The nurserymen are at the bottom of it. They can raise trees better and more cheaply than individual cultivators can raise them for themselves. Let these "go to the bottom" and try—sow seed, select varieties, raise stocks, and graft or in any other way increase the number, and see where they will be ten years hence. They will be at the bottom still, while rival growers who purchased and planted at the time the individualists commenced action in their own isolated way, will be reaping the reward of their trade co-operation with the raisers of the

trees. What we want and what we have is a body of highly skilled, high-minded fruit tree raisers, and we may safely leave the competition, that is a natural element in trade routine, to supply the tree planters to the best possible advantage.

I want to see a great and a growing trade in fruit tree production, and care not how great the prosperity of those who engage in it may be, provided the planters and cultivators prosper accordingly, and the supply of home-grown fruit by its abundance and excellence can hold its own in the competition of the world. Can this be done? Yes, it can when the seasons are favourable for fructification and the development of the crops; and when they are not, we will enjoy what can be obtained elsewhere, and from a consumer's view be thankful that the sun does not cease to shine everywhere, and that all the orchards of the world are not barren at once.

We have, as a consequence probably of our insular position, been in the habit of taking a much too circumscribed view of the great question of the supply of fruit. We did not perceive soon enough the revolution that steam, machinery, and electric telegraphy were effecting and have effected, in bringing the sources of supply, thousands of miles away, practically nearer to us than were many of those of our land to each other not much more than a generation ago. We rested on the strength of our insularity too long. We, that is to say those who had the means for planting trees for maintaining the fruit supply, did not perceive the necessity for change. The old trees were trusted to do what they had done before—provide what would be wanted; and if the fruit should become scarcer through the demand being greater, consequent on the increase of population, the price would rule higher and the owners of the trees would reap the advantage. That was the line of reasoning during the time when Dr. Lardner said he would swallow the first steamship that crossed the Atlantic, and subsequently. It was fallacious, absolutely and ridiculously fallacious, and we in later times, and until now, have suffered by the great delusion.

What was the result—the natural result—of such apathy? Others, more far seeing, in distant lands that were being commercially brought steadily, and eventually rapidly, nearer, did for us what ought to have been done at home—planted trees for supplying our markets and the homes of the million with fruit! Then what did the home neglecters do in return? Only what was to be expected—condemned the introduction of that which they refused to provide; wasted time in railing against it, and waiting for acts of obstruction being passed excluding it from our markets. Vain was the condemnation, futile the efforts of obstruction, and at last the truth was realised that the only certain and practical way of regaining the lost ground—lost by inaction and the slow perception of realities—was to choose varieties of fruit and trees wisely, prepare the ground, plant, and cultivate well for producing an adequate bulk of useful fruit at home, equal in appearance and superior in quality to the samples grown abroad, for meeting the demands of British consumers. That is the right way, undoubtedly; indeed, the only reliable way, unreliable as the seasons may be; the only safe and sound method of procedure under the circumstances; and that it is a profitable way those who were the first to adopt it and carry it out on sound lines were the first to prove the fact, and many a cultivator has reaped the reward of his enterprise, and shown by what he has accomplished what others may do as well as he has done.

Those who have found that the cultivation of hardy fruit can be advantageously pursued in this country are extending their plantations, and others who have seen the satisfactory results achieved are engaging in the work, and every year brings the time nearer when the hardy fruit requirements of this kingdom will, in the absence of adverse seasons, be produced on British soil, and the capital that has so long been expended on imported produce will be invested in labour that will be employed in home production to the direct advantage of the nation.

In England, Ireland, Scotland, and Wales fruit may be and should be grown for the populations. In limited areas it is so grown, and foreign competition is not feared by the producers; but only small patches, so to say, are as yet so occupied, and a great field is waiting to be tilled, while an ever increasing population is waiting for the produce.

It is not suggested here, nor will the proposition gain the sanction of practical men who have gone through the mill of experience, that any town worker or town lounge, if "planted" on an acre of ground, and a number of Apple trees are planted in it for him, will find it a paradise, and as the story ends "live happy ever after." Such teaching as that is misleading. It is in reality trifling with a serious subject. Born on the land, and knowing well the hardships of a peasant's life, I have an earnest longing to see the home of every son of toil made happier by his labour, and I know well that many men

accustomed to agricultural work could, if suitably circumstanced, profit by fruit culture; but forty out of fifty mere townsmen would fail in the effort, just as they would fail in the occupation of other rural pursuits, requiring less knowledge than fruit culture, in which they have had no experience. When agricultural labourers, who in too great numbers find their way into large cities, can be transformed into swallow-tailed and white-cravated waiters in hotels, and there gain a good livelihood, the much-to-be-pitied unemployed townsman will prosper on the land as a fruit grower, and not till then. The great desire, as it seems to me, is to so conduct the operations on landed estates in the country that employment can be given to a greater number of workers, and so keep them out of the too thickly populated towns, where a life of misery is lived by thousands; but the investment in labour to be satisfactory must leave a margin of profit to the employer. Only a very limited number can be engaged for contributing to the luxuries of life. The majority must work on commercial lines and earn a little more by their labour than is invested in it, or the connection cannot long be sustained. The introduction of machinery has lessened the demand for manual labour in agriculture. Fruit cannot be to the same extent grown by machinery, but it can be grown, and more profitably than ordinary farm crops, with the aid of intelligent workers, and far more of these might be kept in their parishes than is the case now, and the amount invested in their labour be remunerative to themselves, while at the same time all worthy, striving, and capable men should, I think, be encouraged to grow fruit also on plots that in many districts might be provided near their dwellings.

Regard the matter from whatever point of view we may, it cannot be otherwise than desirable to find work for labourers on the land. A contented, industrious peasantry is an important factor in the wealth and strength of a nation. Depopulation is an indication of decay, and the dwindling away of the people has never made a country richer, but left it poorer. This must be so, because the strong and most enterprising—the real creators of wealth—are the first to go and become in other lands competitors of their kinsmen at home, leaving the weak, lame, and lazy behind them. These prey on the accumulations of others, hence impoverish instead of enrich the land in which they spend their profitless time and live their luckless lives.

Many of the landowners of the kingdom have it in their power to improve their possessions by increasing the productiveness of the soil by the systematic cultivation of hardy fruit, and at the same time by the necessary employment of more labour do good to others as well as themselves. It is not suggested that they will heap up riches in the work, but if they can add, as thousands may, an interesting and instructive feature to their estates and benefit others, at the same time realising even 5 per cent. on the outlay, is it not better than the 2 or 3 per cent. derived in the old way, with the attendant grumbling of men who can scarcely find sustenance for their families?

I am confident that if fruit gardens of two or three acres, more or less according to the extent of estates and the suitability of soil and position, were established on the residential property of the aristocracy and gentry, also on the glebes of certain of the clergy, that good would eventually result, in which all would share—owners, workers, and consumers of fruit, always provided the varieties of the different kinds of fruit were well chosen, and the best attention (which is the cheapest) bestowed on them in the work of cultivation. I am not now considering the interests of recognised fruit farmers. It is not necessary. They know what they are about, and I trust will increasingly prosper, and at the same time provide the great mass of consumers in large cities with a larger and better supply of wholesome fruit at a lower price than now rules for the best samples. Lower the price of these by increasing the supply, and the consumption would increase enormously, and the aggregate profits of the cultivator would in all probability be greater too.

A gentleman in the Westminster Drill Hall remarked on examining the fruit there last Tuesday, that he had ten children and would like to keep them well supplied with the best fruit; but to give 3d. each for Pears and 2d. for Apples was too much, even for him, and he is not a man of small possessions. If really good fruit could be had at half such fancy prices, he would no doubt buy four times more; and he is but one example of thousands. The prices demonstrate the scarcity of high class fruit and the necessity for growing more, and trees that produce it do not take up half the room that those do which produce the worst.

"Oh," say some, "but if you go on planting, fruit-growing will be overdone." Who do you think preaches that doctrine? Well, I have heard it preached by old fogies who a few years ago said a penny a mile

express fares on railways could never pay, and I have heard it preached by men who have planted thousands of trees and are planting more. Is not that a little significant? They appear to want a monopoly of the industry, but they will not get it. Syndicates can be overdone, and my desire is not only to see the acreage under fruit increase, but the number of its cultivators.

I am going to tell you that the average standard of merit of fruit, and especially of Apples and Pears, in these fertile islands of ours, is miserably, disgracefully low. After examining the magnificent display on the exhibition tables, you may think that a bold statement, but it is true. That splendid fruit, which proves what can be done in England, is no more representative of the real supply than the faultlessly made garments in the best West End shops are representative of the habiliments of the multitude. We have to remember the tattered and torn in that line, and the specked and spotted juiceless trash in the fruit world in striking an average. How do I arrive at my average? I am one of a few individuals who have to handle and examine specimens of fruit sent to be named from gardens and orchards in all parts of the kingdom. Do you think the growers of the samples send the worst? I know that numbers of them say they send the best they could, and regret they could not send better. What, then, do we find? I do not see why the truth should be withheld, but think from every point of view it is better it should come out. The truth is this—not one sample in twenty can, by any stretch of the imagination, be regarded as superior; not half of what we receive is half so good as it should be, and the great bulk can only be properly described as "rubbish." I speak in the presence of others who also spend many weary hours in trying to name bad fruit; and although I have friends on the press evidently generous enough to correct me when they can, they cannot make "copy" at the expense of my veracity in this matter; and that being so, I shall submit with some confidence that the truth, the humiliating truth, of the above assertion, is proved to demonstration.

We have, I am glad to say, fairly commenced a revolution in fruit-growing in this country, and not before time. Some time must elapse before the work is completed, and before the average yield approaches the standard that is set up in the show to-day. Knowledge, practical knowledge, is wanted on the subject. I have nothing to say against colleges to which the rich can send their sons to sit under learned professors, but I should like to see pomological schools, in the form of well managed fruit gardens, on estates in different parts of the country, with collections of the best varieties of fruit grown in them. The founders of such collections would stand to gain by their establishment, while the inhabitants surrounding would have opportunities for acquiring the best of information in the cheapest possible way that might be of substantial value in the cultivation of fruit for their families, and the populations of adjacent towns.

CAN PEACHES AND NECTARINES BE SUCCESSFULLY GROWN AGAINST OPEN WALLS?

[A paper read by Mr. George Gordon.]

ALTHOUGH Peaches and Nectarines cannot in point of general utility be compared with Apples and Plums, they are of more than sufficient importance in the economy of the garden to justify our devoting a brief period to the consideration of the practicability of largely augmenting the supply of their distinctive and luscious fruits. As the question I have to submit to the Conference is "Can Peaches and Nectarines be Successfully Grown Against Open Walls?" I shall not trouble you with the geographical details of their native country, or with the facts bearing upon their early history. Those matters would undoubtedly be full of interest, and enable me to present you with but little effort an attractive paper; but my object is to promote a more extended and rational culture of these fruits in British gardens, and I am fully assured that I shall best serve that object by addressing myself as closely as possible to the question.

It will not be impossible to avoid history altogether, but I shall not take you back to the sixteenth century, when these fruits were introduced to this country. I shall confine my historical details to the period over which my own observation and experience extend, and take you back some thirty years. In those days the production of Peaches and Nectarines out of doors was regarded as one of the ordinary phases of garden practice, and in consequence their cultivation was decidedly more successful than it is at the present time. We had not in those days discussions as to the relative advantages of growing these fruits out of doors and under glass. If fruit was wanted in advance of that produced by the trees against the open walls a glass structure was devoted to its production; but the outdoors trees were depended upon

for the main crop, and in consequence they had careful attention, and as the result they produced crops of excellent fruit. Failures did occur then as now, but they were comparatively few, and taking a run of years the cultivator obtained an abundant supply.

Let us pause to consider why the opinion of cultivators underwent so great a change that in many gardens it has long been considered an unsatisfactory if not a hopeless task to produce a dish of Peaches or Nectarines without the aid of glass. That glass is of immense service in fruit production no one could be more ready to acknowledge than myself, but I would submit that it does not necessarily follow that because Peaches and Nectarines can be successfully grown in an orchard or Peach house, that those who have no such convenience should not have their table supplied with these fruits during some part of the year. The fruit grower cannot wholly escape from the influence of fashion. Thirty years ago saw a great change in the decoration of the flower garden and the uprising of the bedding system, by which the hardy flowers were replaced by bands and masses of colour produced by plants more or less tender. The propagation and preparation of these comparatively large stocks of bedding plants diverted much attention from other departments, and the bedding out had to be done just at the time when the Peach trees require considerable attention. The bedding system undoubtedly exercised a material influence upon the outdoor culture of these fruits; but the chief cause of the decline was not the fever engendered by the bands, crescents, circles, and stars of scarlet, yellow, and blue with which the flower garden was so liberally furnished. Rather may it be traced to the more general introduction of glass houses into gardens about twenty-five years ago. We were then told that to attempt to produce a dish of Peaches or Nectarines out of doors was an act of folly of which no gardener would be guilty. We were assured also that the seasons had so changed that to efficiently protect the flowers and young plants from the cold blasts of spring, or to properly ripen the wood in the course of the season was an impossibility. But this was not all. For many years following the cheapening of glass by the removal of the duty and the adoption of improved processes of manufacture it was too much the practice to attach undue importance to the indoor department of the garden. Twenty years ago the ambition of the majority of young gardeners was to obtain charge of the conservatory and plant stove. Work in the Peach house, Pine pit, and vinery was not particularly objected to, but the pruning and nailing of wall trees was done with reluctance, and the rougher operations of the kitchen garden under protest. In consequence of this combination of circumstances it is not surprising that the outdoor culture of the Peach and Nectarine should have almost become a lost art amongst us, or that the supplies should for a long period have been small and intermittent. Happily a great change for the better has taken place in the ideas of young gardeners, and the Peach and the Nectarine have shared in the improvement that has been effected in the management of the fruit garden as the result of the change. We may, indeed, congratulate ourselves upon the fact that they are now being grown against open walls with greater success than at any period during the past twenty years. Much, however, has yet to be done before their outdoor culture can be considered thoroughly satisfactory. Holding this view, I hope that there will be no relaxation on the part of those who take an interest in hardy fruits to complete this much needed reform.

If I am asked what course we are to take to increase both the quantity and the quality of the fruit, I have no hesitation in saying that it must be in the direction of an improved system of management. I have been told, I am afraid to say on how many occasions, that it is simply a question of climate, and that if we could only change the climatic conditions which obtain, there would be no difficulty in obtaining an abundance of fruit. A change for the better in the climate would, no doubt, be an advantage; but as that is beyond our control, we must endeavour to cheat it by adopting a course of culture suited to the peculiarities of the trees.

As the Peach and Nectarine are natives of Persia, which has a much warmer and drier climate than that of the United Kingdom, it necessarily follows that they are comparatively tender and more susceptible to adverse influences than are the majority of fruits grown out of doors. It is not necessary to tell you that they are liable to suffer from the frosts and biting winds of spring, or from severe weather in winter, following a summer not particularly favourable to the ripening of the wood. But I would submit that their liability to injury in these two seasons is greatly overrated, and that it may be materially reduced by judicious management. Success or failure rests chiefly upon the condition of the wood at the end of the summer, and if that is fairly well ripened, it depends very much upon the activity of the cultivator in

the spring following as to whether or not he gather a good crop of fruit in the course of the summer. To obtain well-ripened wood, excepting in seasons that are particularly favourable, is by many regarded as an impossibility. But I do not so regard it, for to do so would be to ignore the teaching of long experience and wide observation. It is simply a question of placing the roots under proper conditions, and we must obtain clearer views as to what these conditions are, and sweep away some of the cobwebs that hang about the practice which generally obtains at the present time before we can hope to see the culture of these fruits placed on a satisfactory basis. We must fully appreciate the importance of well-drained borders, and to show how necessary they are, I would say that with a superabundance of moisture about the roots, and especially in a stagnant state, the trees will make wood deficient in fibre, and continue in growth until so late a period that the completion of the ripening process is out of the question. Therefore, the steps necessary to prevent the water remaining in a stagnant condition about the roots must be taken either before or after the borders are formed. Anxious to avoid occupying time with more detail, I will content myself with saying that a drain laid down along the front of the border, 6 inches or so below the bottom of the border, will suffice to carry off superfluous water. In other cases it may be necessary to supplement the drain with a layer of brick rubble or broken stone underneath the border. On soils that are naturally cold and heavy it is a great advantage to raise the surface of the border from 12 to 18 inches above the general level, and to separate the border from the cold subsoil by a layer of lime concrete. To provide a layer of drainage materials or of concrete will undoubtedly add to the cost. But I would submit that one of these provisions would be made by the experienced cultivator in forming a border for trees under glass when the soil is wet and cold. Then why not make a similar provision for trees in the open which are assuredly less favourably placed?

Referring briefly to the formation of the borders, permit me to say that a good strong loam is the most suitable for Peaches and Nectarines. But there are comparatively few gardens in which they will not thrive without any additions being made to the staple. Here it may be necessary to consolidate a light sandy soil by a liberal addition of loam brought in from the outside, or a moderate quantity of well-pulverised clay. There the staple may be so heavy and tenacious as to render a liberal dressing of some light material desirable. To break up the border to the depth of 2 feet or so will be advisable, but this must be done a sufficient length of time to enable the soil to settle down before the trees are planted. It is a good practice to trench the border in the winter, then crop it during the summer, and plant the trees in the autumn following. Not a scrap of manure should be added to the border when prepared. I know that we are told in the books and elsewhere that as the trees will in all probability occupy the same positions for many years, the borders must have fertilising matters added to them when under preparation. This mischievous teaching is not modern, and has much to answer for. Planted in a rich border the trees grow with excessive luxuriance, the knife is freely used in the removal of fat shoots, and gumming, with a whole train of evils, follows as a matter of course. To abolish the use of manure in the formation of the border will be a great gain, as we shall then obtain a firmer and more satisfactory growth from the first. Let it not be understood that I am advocating a starving system of culture. So far from this being the case I would suggest that when the trees have commenced to bear, and not until then, they should have whatever assistance from fertilising matters that may be necessary, for to obtain first-class fruit from trees that are not in a vigorous condition is impossible.

Passing on to a reference to the trees, I would submit as the most suitable those that are in a moderately vigorous state, and have undergone some amount of training in the nursery. I would also give a preference to trees on the Mussel stock, and showing but few signs of the knife. In pruning the trees during the first two or three years, a course intermediate between that generally adopted by the past generation of cultivators and that which now obtains will give the best results. The older growers cut the leading branches the first season back to about one-third of their length, and in subsequent seasons pruned severely. By this means they obtained trees well furnished from the base, but the work of filling the wall space was slow, and the production of fat shoots gave much trouble. The cultivator of the present day contents himself the first and several subsequent years with merely taking off the tops of the leading shoots. Under this course of procedure large wall spaces are quickly covered, but in the majority of cases the trees are indifferently furnished with bearing wood in the centre. From the first overcrowding of the growth must be avoided, as it is only

by allowing each shoot sufficient space for the full development of the leaves that strong well-ripened wood can be obtained. Further, all the shoots that will not be required should be removed at a comparatively early period of the summer, the precaution being taken to proceed gradually with the work, that the trees may not be subjected to any material check. At the commencement of the disbudding the cultivator must determine what shoots will be required for laying in, and having selected those occupying suitable positions, must so shape his course that no shoots beyond what are absolutely necessary are laid in. To lay in two or three times as many shoots as are required, in case they may be wanted, as is frequently done, is one of the several hindrances to Peach culture, and the practice cannot be too strongly condemned. The summer disbudding should indeed be so carried out that the winter pruning will consist chiefly in cutting away the shoots that have borne fruit, and shortening those of the previous season.

To discuss the relative merits of varieties would be interesting, but to do so would be to go beyond the scope of my paper. But as having a direct bearing upon the question under consideration, I would urge the more extended culture of the excellent early Peaches and Nectarines raised at Sawbridgeworth, and the fine early Peaches received from America, more especially on soils and in districts not particularly favourable to these fruits. Ripening their fruit in the second half of July and at the beginning of August they complete their growth early, and plenty of time is afforded the wood to attain full maturity. They are also of service in greatly prolonging the season, a point of no small importance in gardens of all classes. Concurrently with an extension of the culture of the early sorts there should be a reduction in the space devoted to the late kinds, for under the most favourable conditions only are they even moderately good.

There is only one other point to which I would direct the attention, and that is root pruning. This phase of Peach culture seldom receives the attention its importance demands. We see in all direction trees producing fat wood, and we see also cultivators endeavouring to check the production of wood of this description by cutting away the strong shoots at their base. If it is necessary to check an undue luxuriance of growth the roots must have attention, and they may be simply shortened or the trees be lifted and then have the roots shortened according to the condition of the trees. When they have occupied the same position several years without being disturbed at the root, it is necessary to proceed cautiously with repressive measures. But in all cases it is essential to shorten any strong roots that may have struck down into the subsoil, for in no small degree do they promote the production of soft unripened wood. It is indeed necessary to keep the wood near the surface, for to have them within the influence of the sun and air is a prime factor in the production of an abundant supply of richly flavoured fruit.

APPLES.

[By Mr. R. Smith, Yalding.]

NOTWITHSTANDING the foreign competition I maintain British growers could hold their own in the English markets if they would spend more time and labour upon the trees in the orchards, and keep the Apple trees clean from lichen and insects. Nothing improves the bark of Apple trees more than whitewashing the stems and all the large branches with lime. I have noticed the last few years how clean and bright the bark has looked in the spring after being whitewashed a year or two ago. I strongly recommend throwing powdered lime into the heads of large Apple trees during the autumn and spring months—as soon as the leaves are off in autumn, and before the buds swell in spring. This work is not costly, and can be done by any handy labourer.

I find the Apple trees in orchards, say forty or fifty years old, have very little time and attention devoted to them. Here is the great error. From the small wood in the heads of such aged trees yield very inferior fruit, and such helps to glut the market. If the British Apple grower for market is to hold his own in open competition with the foreign growers he must use every means in his power to grow only good fruit. This means high class cultivation. That is what the Apple wants. It is the high-class cultivation that I wish to impress very forcibly upon the grower. I have here two samples of Apples taken from old trees from an orchard. These trees have been cleaned as advised above. These specimens are equal in size and colour to any from young trees of the same variety; one is Beauty of Kent and the other is a local variety called Brenchley Pippin, a seedling raised at Brenchley in Kent, rather small Apple, but as shown is of fair size and good colour, much like the King of the Pippins in shape, and for size of a well grown King. This Pippin is an excellent cropper. I have never known it fail in twelve

years. But what I want to point out is that good sound Apples can be grown on aged trees in the orchard if properly cared for as to pruning and keeping them clean and manuring, not disturbing the roots by digging about them. Keep the land well mulched with farmyard manure from time to time—that is, in autumn and summer. Aged trees want a little pruning every year, rather than a severe pruning occasionally. I have no doubt whatever the British Apple grower for market has many drawbacks. He wants more security of tenure. This will come before long. The landlord begins to find out it is to his own interest that the tenant has security for his investment of his own capital on the land he holds.

Every Apple grower for market should make a point of visiting his neighbours every autumn, as much would be learnt in this way. No doubt a few would be found who would go in for high-class cultivation and planting the best varieties suitable to the districts. Many mistakes have been made in not getting the right sorts for the localities, consequently a great loss of time and season is the result.

EVENTS OF THE WEEK.—The Royal Horticultural Society's Fruit and Orchid Committees will meet in the Drill Hall, James Street, Westminster, on Tuesday, October 22nd, at 11 A.M. The National Chrysanthemum Society's Floral Committee will meet at the Royal Aquarium, Westminster, at 2 P.M., on Wednesday, October 23rd. On the last named day the Horticultural United Provident and Benefit Society's Annual Dinner will take place at the Cannon Street Hotel at 6 P.M., N. N. Sherwood, Esq., in the chair. Tickets can be had from Mr. W. Collins, 9, Martindale Road, Balham, S.W.

— **THE FRUITERERS' COMPANY'S PRIZE FUND.**—Amongst the subscribers to the fund of £5000 now being raised by the Fruiterers' Company for the encouragement of fruit growing in England are His Grace the Duke of Westminster, £50; His Grace the Duke of Newcastle, £50; Her Grace the Duchess of Grafton, £5; the Earl of Dartmouth, £20; Lord Crewe, £5 5s.; Lord Wolverton, £10 10s.; the Baroness Burdett-Coutts, £50; the Right Hon. W. H. Smith, M.P., £20; Messrs. Crosse & Blackwell, £52 10s.; C. A. Sperati, Esq., £21; F. Gorringer, Esq., £10 10s.; R. Barrow, Esq., £5 5s.; and J. H. Cunningham, Esq., £5.

— WE learn with regret that MRS. M. WILLIAMS died at the Victoria and Paradise Nurseries, Upper Holloway, on the 10th inst., and we express our hearty sympathy with the veteran horticulturist, Mr. B. S. Williams, on the loss he has sustained.

— **GISHURSTINE.**—Price's Patent Candle Company usually remind us of the approach of winter by sending samples of this valuable dressing for boots. It is largely used not only by workmen on the land in wet weather, but by young men who are employed under glass, where much watering and syringing has to be done, and is found to exclude wet and act as a preservative of the leather.

— **HEAVY YIELD OF POTATOES.**—A correspondent sends us a record of the proceedings in taking up and weighing the crop of half an acre of Potatoes in the middle of a field in Yorkshire, as grown under ordinary farm management by Mr. John Shelbourne. The tubers, which are stated to be of extraordinary size, weighed 9 tons 4½ cwt., or 18 tons 9 cwt. per acre. The variety is new to the district, and is named Excel All.

— **PLANT AND TREE LABELS.**—We last year referred approvingly to Chandler's copper labels, some samples of which are now before us. They are as thin as paper, and when laid on a soft pad and firmly written on with an ordinary pencil or style, the names are indented and remain legible no doubt for years. They require no string or wire attachment for placing round the trees, the tags for this purpose being part of the labels, and, being flat, do not cut the bark.

— **MANDEVILLA SUAVEOLENS.**—In your issue of September 26th the question is asked, "Who has tried it in a cold house or against a wall?" In the island of Guernsey it grows freely out of doors. I have

had two plants on a south wall of my house for twenty-two years, they bloom well, but only seed in very warm summers; and on another house with an eastern aspect there is now a fine plant covered with blooms. I consider the *Mandevilla suaveolens* quite a hardy creeper in this island.—C., *Guernsey*.

— **LIQUID MANURE FOR FRUIT TREES.**—I should like to ask Mr. Edmund Tonks what good liquid manure would do for my fruit trees during winter. I should say no good at all, for in winter the soil is cold and clammy. I can answer for the land being well drained. Some Apples and Pears are 18 inches through the stems. Does he think on such land he could with safety use liquid manure if he had the working of it? I think his answer will be a loud "No." I prefer a good mulching of leaves and stable manure.—R. H. S.

— **THE THAMES BANK IRON COMPANY** desire us to state that they have made important improvements in the "Champion Horizontal Tubular Boiler," expansion and contraction being now effectually provided for by the substitution of compressed indiarubber rings for caulked sockets; also that in the event of a pipe requiring to be replaced at any time, this can now be done in a few minutes without disturbing the brickwork setting. These boilers, we are informed, are in great request for trade establishments and private gardens.

— **WE** have to announce the death of MAJOR A. F. LENDY, which took place at Riverside House, Sunbury-on-Thames, on October 10th. Major Lendy was for some years a Fellow of the Royal Horticultural Society and a frequent visitor at the shows and meetings. He formed a good collection of Orchids at Sunbury House, including many rarities, but, owing to his failing health they were recently sold by auction. Major Lendy was also a Fellow of the Linnean and Geological Societies, formerly captain of the French Staff, and major of the 4th Middlesex Regiment. He was in his sixty-fourth year.

— **WAKEFIELD PAXTON SOCIETY.**—At the last meeting of the members of this Society at Councillor Lupton's, the Saw Hotel, Mr. Squire Pickersgill presided, and Mr. G. Gill was in the vice-chair. Mr. W. Grix, gardener, of Gledhow Hall, near Leeds, read an excellent and practical paper on "The Gardenia." Mr. W. Hudson of Sandal Grange and Mr. Fenner of The Woodlands, Sandal, put a few questions to the essayist, and after they had been satisfactorily answered, Mr. T. Garnett proposed a vote of thanks to Mr. Grix, and this was seconded by Mr. B. Whiteley, supported by the Chairman, and heartily carried.

— **READING AND DISTRICT GARDENERS' IMPROVEMENT ASSOCIATION.**—The opening meeting of the autumn session of this Association was held on Monday last, when the members attended in large numbers to hear a paper on "Peach Culture" from Mr. Wm. Lees, Chairman of the Association. Unfortunately, however, Mr. Lees met with a somewhat serious accident a few hours previous to the meeting and was unable to attend. His paper was read by Mr. Turton of Maiden Erlegh, and was much appreciated by the members. Mr. Jas. Martin occupied the chair. Judging from the attendance at this, the first autumn meeting, together with the capital programme that has been arranged, the session promises to be highly successful.

— **A FRENCH translation of Mr. Lewis Castle's ORCHIDS; THEIR STRUCTURE, HISTORY, AND CULTURE,** has been prepared by M. A. de Meulenaere, Secretary of the "Orchidophiles Belges," and has just been published in Ghent by F. & R. Buyck Frères, 13, rue de la Tour Rouge. It comprises 189 pages, the list of Orchid illustrations having been extended by the addition of numerous references to continental works, and the list of Orchid amateurs includes the names of those in England, Germany, Austria, Belgium, France, Holland, Italy, and Switzerland. The English list, which was taken from the third edition of Mr. Castle's book (published nearly two years ago), requires some revision, but the directory altogether will be found very useful. The translation has been admirably rendered; the book is well printed, and neatly bound in green cloth.

— **THE WEATHER AND PLANTS.**—Our Lanarkshire correspondent writes:—"The present year has had its peculiarities, as every one has, on some plant or plants. For example, last year *Erigerons* bloomed with me in August; this year, although warmer and the plants stronger, they have not bloomed at all. The same may be said of *Coropis lanceolata* and a *Statice*, while for the past twenty-five years *Gloire de Dijon* Rose has not made such strong shoots. Wallflowers in 1888 took the whole summer to complete their first flowering spikes; this year they have

completed their first flowering, ripened their seeds, and are for the second time in profuse bloom. A better example of giving annuals every opportunity of developing their growth may be seen in a border of *Mignonette*, the plants 18 inches apart in the row have extended to 5 feet across. The autumnal *Colchicum* began to flower on the first day of September, and has continued until now. We have had copious rains lately. Frosty nights have also been frequent, but never so severe as to injure the most tender plants; most of them, especially single *Dahlias* and *Mignonette*, affording a liberal supply of flowers."

HEYSHAM HALL.

BEING in the neighbourhood of Heysham Hall, the residence of F. W. Grafton, Esq., we paid a visit one morning to the gardens there. Mr. Lomas, the gardener, was at home and busy as usual. He at once conducted us to the conservatory, a handsome structure built in the Queen Anne style, one end adjoining the mansion. It is well furnished with plants, the roof with suitable climbing varieties, and at each side of the pathway down the centre with *Liliums*, early flowering *Chrysanthemums*, and other plants, both flowering and fine-foliaged, including *Palms* in the best of health, the borders being planted with *Selaginella*, which gives to the whole a fresh appearance. We next made a tour of the pleasure grounds, passing through the orchard on the way. Apples and Pears were good crops, some of the Apples, notably Warner's King, being very fine. The trees were healthy, not a sign of canker. Damsons also were a heavy crop. Both Apples and Pears were quite up to the average. The orchard is in a sheltered position, and in one equally so is situated an herbaceous garden laid out in the old style with gravel walks and Box edgings. This garden was designed and planted by Mr. Lomas, not the least interesting feature in it being the labels attached to each plant, which bears the common and botanical name of the variety, and in most instances their native habitat. This is well worthy of imitation by all who intend planting, or have herbaceous borders. I must not attempt to name many of the plants grown, the majority being past their best; but sufficient were then in bloom to show what a grand sight it must present. Carnations are largely grown, a place being found there for Mrs. Reynolds Hole, *Gladiolus*, single *Dahlias*, and *Sunflowers*; one a double variety resembling somewhat a *Cactus Dahlia* flowered in England for the first time this season. The terraced flower garden, from which a beautiful view is to be had of Morecambe Bay, was gay with *Pelargoniums*, *Calceolarias*, and other plants in beds in keeping with the situation. The terrace walls are covered with *Ivies*, and in small beds adjoining these walls are *Roses* in good health and still producing fine blooms. On the opposite side of the mansion several carpet beds looked very well; other beds are occupied with Carnations, Tuberous *Begonias*; and one bed with *Verbenas* had a bright appearance.

In the fruit houses the early Peaches and Grapes were over, but a few bunches of Grapes were still hanging, which gave one some idea of the fine crop previously gathered. The houses of Vines were still interesting to the gardener, for the wood was short-jointed and ripened, promising well for another year. The Grapes in the late houses were finishing well, and fine both in bunch and berry. Pine Apples were producing medium-sized fruits, and in an adjoining house Tea *Roses* trained over an arched trellis had done good service. Tomatoes in another house with late Peach trees on the back wall were hanging in fine bunches; the wood was not gross, but healthy, and bore fruit very freely. They were planted in boxes along the front stage of the house and the shoots trained up under the roof. I must not omit mention of a house of Tuberous *Begonias*, chiefly single varieties; they presented a grand sight, some of the individual blooms being quite 6 inches across.

Stove and decorative plants are grown in other houses, all having the appearance of great care being bestowed upon them. *Chrysanthemums* are not grown here on the large bloom system, but fine healthy plants are coming forward for decorative purposes. Strawberries in pots for forcing are grown in large quantities, and appear to be thoroughly established in their fruiting pots.

In the kitchen garden we noticed good examples of Brussels Sprouts, President Carnot, Leicester Red and Sutton's White Gem Celery, Beet, and Peas, giving promise of plentiful gatherings for some time longer. The walks, and indeed all parts of these gardens, were scrupulously clean, no quarter being given to weeds, the whole reflecting great credit to Mr. Lomas, with whom a most pleasant morning was spent.—G. GARNER.

TREATMENT OF SOILS AND MANURES.

BEING entitled to reply to Mr. Tonks' remarks on page 314, I will be as concise as possible. The fact still remains that carbonic acid is deposited upon the surface of the soil in the form of carbonic dioxide, notwithstanding the diffusion of gases. I would ask Mr. Tonks a few pertinent questions, but as he states he has finished in this discussion it would be taking up space needlessly to do so. I began my articles with a view to impress upon those gardeners and others having plenty of solid and liquid manures the desirability of making the best use of them, and tried to prove that they could then produce as good vegetables and plants as others having at command unlimited quantities of manufactured manures. I did not condemn them, and had Mr. Tonks

waited he might have found me advocating them in some cases, and I fail to see that he has proved anything in opposition to my views on that subject.—G. A. BISHOP.

JOTTINGS.

THE Royal Horticultural Society's Orchid Nomenclature Committee will shortly meet to discuss an important question—the improvement of the present system of naming Orchids; and it is to be hoped in the interests of all concerned that the members will give the matter their most careful consideration from every point of view before adopting any revolutionary method. It would be easy to frame a series of rules for the regulation of nomenclature, but it is impossible to enforce these except so far as regards the Society's own meetings, and unless they are drawn upon a very

at Streatham, and was generally respected. Both were comparatively young men in full health. Mr. White has opened the fund with a subscription of £50.

At the Royal Horticultural Society's recent meeting (October 8th) several noteworthy Orchids were shown, not the least remarkable being the handsome raceme of *Vanda cœrulea* from Tring Park. Mr. Hill informs me that he believes the cause of the exceptionally deep colour distinguishing the specimen was the fact it had been somewhat freely exposed to air, as in the *Cattleya* house it was placed immediately under the ventilators. During the summer and in fine weather these were fully open, and in consequence the plant had been for a long period in an almost continuous current of air. When possessing the deep blue colour of this specimen the accuracy of the name can be fully appreciated; as a rule the washy flowers are far from cœrulean.

The variety of *Cattleya Hardyana* from Mr. E. G. Wrigley, Howick House, Preston, awakened some comment, as some slight differences were noticeable between that and what is regarded as the true type, which originally appeared in Mr. Hardy's collection at Pickering Lodge. *C. Hardyana*, it may be remembered, is regarded as a natural

FIG. 40.—*LÆLIA PRÆSTANS ALBA*.

broad basis and are free from every suspicion of "faddism" they are not likely to meet with general acceptance. This would be lamentable, as the present confusion is bad enough, but it would then be increased tenfold, and further it is quite probable that the exhibits placed before the Orchid Committee—already far from as numerous as they should be—would soon be decreased if exhibitors found the names of their plants altered in a manner they disapproved. Every effort should be employed to obtain the opinions of orchidists throughout the country, and the Committee ought to have included at least three times its present number of members to secure anything like an adequate representation of the general views on the subject.

It is very satisfactory to learn that a fund has been opened on behalf of the widows and families of the late Mr. W. Hall of Tulse Hill and Mr. R. Fraser of Ardarroch, Mr. Harry J. Veitch being Chairman, Mr. Protheroe the Treasurer, and Mr. Fred. Horsman, Colchester, the Secretary. Both the unfortunate men were well and widely known in the Orchid world. Mr. Hall was perhaps better known in the neighbourhood of London, and won the esteem of all who knew him by his straightforward business habits and genial manner. As the Secretary of the Brixton Chrysanthemum Society he gained the good opinion of all with whom he was associated. Mr. Fraser was for some time in charge of Mr. Measures' Orchids

hybrid between *C. Dowiana aurea* and *C. gigas*, was imported with the last named, and found its way into several collections, but first flowered with Mr. Hardy. From the latter a plant was exhibited before the Royal Horticultural Society at South Kensington on August 11th, 1885, when a first-class certificate was awarded for it, and it was thus described. "The flowers are of great breadth, but the sepals are not very broad, the colour being a pale purple; the lip is 3 inches broad and 5 inches deep, of an intensely rich crimson colour at the top, gold at the side, and beautifully veined with gold in the centre and throat." In the variety shown by Mr. Wrigley the sepals and petals are much deeper in colour—a purplish crimson hue with lighter veins, the lip deep gold at the base and intense magenta at the tip, some of the colouring extending to the base of the lip. It was equally beautiful, but some better name might have been found than Wrigley's variety.

An Orchid that was greatly admired at the meeting named was *Lælia præstans alba*, *L. præstans* being now regarded as a variety of *L. pumila*, and *L. Dayana* is assigned a similar place. The variety *alba* (fig. 40) shown by Mr. W. Bull, is a delicate little gem, and one of the most charming of the small flowered dwarf *Lælias*. The sepals and petals are broad, pure white, the base of the lip also being white and finely contrasted with the rich crimson upper portion of the lip. The type of *L. pumila* has been found growing

upon trees in the Rio Janeiro province, at an elevation of 2000 feet or more. *L. præstans* came from Santa Catherina, but is not so well known in cultivation as *L. Dayana*. The variety *alba* was sent to Mr. Bull in June, 1838, probably from the same locality.

Another notable Orchid was exhibited on the same occasion as those above named—i.e., *Cypripedium picturatum* (fig. 41) from Sir Trevor Lawrence, Bart., M.P., and it also was awarded a first-class certificate. In shape and general characters the flower is suggestive of *C. Spicerianum*, especially in the dorsal sepal, which is white with green and purple veins, the central vein being strongly marked exactly as in that species. The petals are greenish at the base with a few crimson dots, the margin undulated, with some scattered dark hairs, the even polished lip of a purplish hue, as also is the staminode. It is a peculiarly elegant flower, and a good addition to the list of hybrids.—L. CASTLE.

CANKER AND ITS CURE.

THE word canker means a disease in animals and plants, and when it is seated deeply in the former its eradication is almost

and sandy, or wet, retentive clay—often water-logged; and as soon as the roots were removed into good surface soil disease disappeared. I beg to offer a few remarks from many notes taken from several districts in England and Scotland. When I was an underling in a first-rate Wiltshire garden there was a fine collection of hardy fruits—Apples and Pears especially—which evidently had been planted with much care; but rich soil, which caused strong, watery growth, which was annually cut back to keep the trees to a given size, caused ulceration in the trunk and branches and cracked fruit, often small in crop. Cutting away the roots entirely underneath and inducing them to become fibry near the surface changed matters speedily, and had permission been granted I would have operated on all the trees on walls and in the orchards as well, as few were entirely free from canker. Taking another case into consideration, I was entrusted to renovate an old place in East Anglia where espaliers had at one time been nearly perfect but had gone wrong by deep rooting into wet clay and hard cutting out of young wood annually. The removal of downward going roots and the placing of plenty of broken bricks and lime rubbish underneath and mulching on surface put an end to canker, and the wounds all healed.

Some years after I removed to manage a good Scotch garden,

FIG. 41.—CYPRIPEDIUM PICTURATUM.

impossible. It is caused generally from want of proper food, living in an unwholesome atmosphere, or neglect of cleanliness. With plants its cause is from the same sources, and the removal of the evils which cause the disease, when not beyond recovery, soon tell most potently on the plant. Causes do not always lead directly to the same effects. There may be exceptions, but seldom do we find unhealthy plants sound at their roots; and starvation, superfluous supplies of food and moisture, and stagnation caused by bad drainage, are some of the evils most generally met with which cause canker. Shrubs, trees, and pot plants of every description we have had under manipulation for canker, and have in every case seen the disease removed when natural laws, which had been violated, were righted.

The many interesting articles on canker of fruit trees I have read have revived afresh a subject which has given me an experience of a mixed character. Since my earliest recollections of work associated with practical gardening, and in nearly every case where canker has occurred, it has been traceable to soil strongly impregnated with iron, or roots growing into unsuitable subsoil—inert

where a clever predecessor had made strenuous efforts for years to establish a good collection of hardy fruits, and he did so with much credit to himself, but the handsome trees being mostly dwarf bushes 6 feet in height, and the same in diameter, would persist in giving way to canker. They had been planted high on a great depth of maiden loam, which gave a clean growth and healthy foliage, but in the course of years the roots found their way down into a subsoil of inert soil, sandy, with traces of iron through it. The bottom roots were cleanly cut away, and a layer of brick and lime rubbish firmly rammed below, with good soil from the surface placed next the roots. The change in the trees and fruit as early as the first season was patent, and though some of the branches were almost eaten through with the disease they began to heal as soon as the roots supplied with nutriment from the healthy soil only, and these being cut off from the poisonous soil in which they had been some time embedded, changed the character of the fruit as well as wood and foliage. Pears, Plums, and Cherries were manipulated piecemeal, extending over a period of several years, and fruit became abundant. Passing over time and distance, we had

some peculiar experience in Worcestershire, where new gardens, park, and grounds had been stopped during their formation, and while clearing away the work which had been going on for years, we found among quantities of shrubs, heeled in, a number of bundles of fruit trees among the trees and shrubs. They had been planted somewhere, but injured by sheep, and removed to the outward quarters where we found them. All that seemed worth planting were trimmed at the roots, dead branches removed, the mutilated stems washed and brushed over with lime. They were all standards, Cherries and Apples. They were planted in rich soil and mulched. In the course of two years afterwards the decaying bark was healed and the trees were in robust health, bearing abundantly, and called forth expressions of admiration from the late Archdeacon Lea, who was one of the best judges of hardy fruits I ever knew. His death we deeply deplore, and will miss him as a kind friend who commanded the esteem of all who knew him. Many horticulturists especially, will deeply regret his removal and lose his kind sympathy and judicious advice. Many singular episodes might be related which occurred in this Worcestershire garden while endeavouring to make a good fruit garden, but we pass on to our present position, where root lifting and pruning is at present going on apace, and can look on trees loaded with fruit which were left to go wild for over half a century, and were cankered so much that bark and wood were nailed over the wounds of some of the old trunks. Even old trees of the character indicated are not beyond a remedy, and their recuperative powers astonish me.—M. T.

MALVASTRUM GILLIESI.

It is well for the future of this little alpine that the evil odour which is generally associated with the use of an alias in human life does not follow the possession of a synonym in plant life. Were such the case the reputation of this little beauty would be hopelessly injured, as in addition to the name given above it is generally called *Modiola geranioides*, and at one time rejoiced under the name of *Malviscum geranioides*. I have no knowledge of the genesis of any of these names, having received the plant some three years ago from a most reliable source as *Modiola geranioides*, which I am bound to say is more euphonious than *Malvastrum Gilliesi*, which I have adopted on the strength of the well-known firm from whom I received my plant, and who now catalogue it under this title. Less musical this may be, but we may be thankful that *M. Gilliesi* is a native of North America, and not of Central Asia, or it might have laboured under some of the "owsks" or other combinations so frequent in the names of plants received through a Russian introducer.

This is one of the extremely small number of plants belonging to the natural order Malvaceæ which are worthy of cultivation on rockwork. Looking over an extensive catalogue of alpines the other day I noted with some surprise that this *Malvastrum* and *Callirhoe involucrata* were the only plants of this order catalogued. It forms a neat, dwarf, slender-looking plant some 4 or 6 inches in height, formed of finely cut leaves, bearing some resemblance to some of the *Geraniums*, or to one or two of the scented-leaved *Pelargoniums*. The leaves and stems die in winter, and in early summer new ones proceed from the root, which is tuberous, and bears a resemblance to a single tuber of a *Dahlia*. The flowers, which are of a beautiful crimson-purple with a fine satiny lustre, are about 1 inch across, and are freely produced over the plant on short stems raising the erect flowers well above the foliage.

It grows very freely on a high, dry, sunny part of the rockwork, in light, rich, sandy soil, and late in summer sends out runners, which will root at every joint. These I take off and insert in pots in sandy soil until fully rooted.

One weak point in *M. Gilliesi* is that it will not flower unless in full sun, and only when the sun shines, the flowers being easily destroyed by a heavy shower.

The summer of 1888 was a most disappointing one in this respect, as I had only one fully opened flower. This year, however, has recompensed me for last year's non-success, and so lately as October 6th I had the pleasure of seeing a flower fully open. So far as my experience goes the *Malvastrum* is perfectly hardy, and as it is now moderate in price should be more frequently met with.—S. ARNOTT.

NOTES ON EARLY ENGLISH HORTICULTURE.

(Continued from page 199.)

It does somewhat astonish us to find how slowly that valuable esculent the Potato advanced in public favour during the seventeenth century. Wits have attributed this to unfortunate methods of cooking. Early in the reign of Charles II. a Somersetshire

gentleman named Buckland called the attention of the Royal Society to this vegetable as one likely to furnish a staple article of food, and he urged those members who owned land to plant Potatoes freely, also to recommend the practice amongst their friends; but little seems to have been done, and Evelyn refused to take the matter up—indeed, he subsequently, in his "Gardeners' Kalender," wrote slightly of the Potato, telling gardeners to plant it in any soil, and dig up the tubers about November, when, few or many, there would be quite enough. Woolridge, in 1687, suggested that Potatoes might be grown in quantities to feed swine or cattle, and he adds the statement that some gardeners planted them in order to use them for forcing fruits, which seems somewhat ambiguous; but I presume they were allowed to decay, and then applied as manure to the roots of trees or plants in the early months of the year. That the London gardeners had acquired some skill in forcing by the middle of this century appears from an account of a banquet given to the king on April 23rd, 1667, when, amongst other fruits placed on the table, ripe Cherries and Strawberries are specified. From references made by some writers to the use of dung in forcing, it seems that about this time the gardeners not unfrequently placed manure against a wall of boards, and not directly in contact with the plants they wished to force, applying side heat to their frames, not bottom heat; these were often sunk deeply in the earth. It is likely that the dishes of early Peas, raised at a period when hothouses were certainly unknown, were obtained from plants set in pits and covered at night with cloths.

There was an increased cultivation of the Fig and Orange in the reign of Charles II. The fame of the orangeries at Kew, Beddington, and elsewhere made the Orange a fashionable tree, and numbers of young Oranges were brought over from Italy. These were planted in boxes, and placed in a row during the summer along the principal avenue of a residence, sometimes alternating with Figs similarly planted in boxes. Only two varieties were then known, the Black Syrian and the White Marseilles. They were also arranged along walls, but the yield of fruit was small. Melons were planted freely on the low ground near the Thames in Surrey and Middlesex. It is doubtful whether the gardeners succeeded with a plant which so much needs warmth. References to "King" and "Queen" Pines occur about this time. These, I think, were probably imported. Attempts may have been made to grow the plant here, but they hardly obtained fruit till a later period, when stoves had been contrived.

No important additions to the English stock of Apples and Pears seem to have signalled the reign of Charles, though what was first called Scudamore Crab, and afterwards the Redstreak, brought by that nobleman from France before the civil war, and for years confined to a few orchards, was distributed over the country. The Catherine Pear is said to have been named after the queen, a small early ripening sort, still supposed to be in existence. It was by the order of this king that lines of Apples and Plums were planted round St. James's Palace, which led many of the nobles to follow his example at their residences. A curious account is given by an old author of the spring garden at Vauxhall, laid out as a public resort, and planned in squares of about 20 yards each. As this chronicler notes that in one of these squares he saw growing Roses, Beans, and Asparagus, the arrangement then was apt to be rather mixed. More important is the fact that there were hedges of Gooseberries, so now this shrub has fairly arrived south. First cultivated in Lancashire it travelled slowly across England, and Ray mentions yellow, blue, white, and green, the yellow kind being most esteemed.

Towards the close of the seventeenth century quite thirty varieties of the Vine are enumerated, but not above a dozen of these had any importance. Lord Capel and Sir William Temple imported several varieties. The latter is credited with six, named Chasselas, Parsley, Frontignac, Amboyne, Burgundy, and Black Muscat. But to John Rose, at first gardener to the Duchess of Somerset, and afterwards to the king, belongs the credit of having, by his "English Vineyard Vindicated," published in 1666, encouraged the culture of what he styles the "Prince of Plants," and which he thought was falling into neglect. Also he was a dealer in Vines, for his book ends with the statement that "he had a plentiful stock of sets and plants of all those sorts which he chiefly recommended." His instructions are carefully given, and particulars added as to the varieties yielding most fruit, or best adapted for wine making. With the next and much advanced generation of gardeners Rose is linked by his connection with London, who worked under him when a young man. At the request of Rose he was sent to France so that he might inspect the Versailles gardens, and some others reputed to be examples of the art of laying out. Concerning Rose's skill in ornamental gardening we get little information, we read, however, that his lawns and walks were highly commended; also, it seems, he rather objected to borders, preferring to cultivate flowers in beds or plots. Rose died in 1677,

showing his interest in education by endowing a school at Amesbury in Wiltshire.

The Lettuce, a name found in old gardening books as "lactuse" or "lectuce," pointing evidently to its derivation from *lactuca*, was not much grown till after the restoration. An increased demand for this vegetable may have been caused by its repute as a remover of the effects of deep potatoes. Our gardeners had first some varieties of the Cabbage Lettuce from Holland, and these were succeeded by the Cos and Cicilian kinds, brought from the Levant or Italy. We should be surprised at the space allotted in the seventeenth century kitchen garden to the now neglected Rocambole, to the Leek, Onion, Chive, Shallot, and Garlic. The latter was much favoured, especially in the spring. And during the terror caused by the plague, milk in which Garlic had been boiled was freely used as a supposed preventive. Owing to the fancy our ancestors had for winter salads several plants were grown for this purpose, which have ceased to be in requisition. Our native species, the Burnet, was cultivated for winter cutting, as was also the Tarragon and other plants of the Cress tribe which could be forced by slight heat, such as the Rocket. The white Beet had been grown for some years, the leaves being put into soups. Though a native of Spain, it seems to have come to England by way of France. Tradescant the younger brought the red Beet from France or Italy, and planted it in his garden at Lambeth. It was eaten with bread like the Radish. Neither Turnips nor Carrots had as yet obtained any popularity, but the Parsnip recently introduced from Holland was in request, the roots being sometimes mixed in flour to make bread, and a decoction of the seeds given in fevers; this plant was also oddly called "Mypes." The additions to our list of exotics during this reign were not very numerous. The Tulip continued to be a favourite flower owing to the influence of the Tulip mania on the Continent. We find the varieties arranged in three groups as "early blowers," "late blowers," and "doubtful blowers." Of the *Ranunculus* twenty varieties were reckoned in 1665. The *Auricula*, which few would recognise by its name of "Mountain Cowslip," was only grown by a few gardeners. The showy *Pæony* was a favourite adornment of the flower beds near windows, and the pyramidal Bellflower or *Campanula*. A conspicuous flower brought from Virginia, *Lobelia cardinalis*, was occasionally to be seen beside the little ponds so common in gardens and the water-loving *Mesembryanthemum*. Not much heed seems to have been taken of the Rose; several of the noted Rose gardens about the metropolis were destroyed during the Civil war.—J. R. S. C.

TREE CARNATIONS.

MR. DUNKIN has recently spoken very favourably of the variety Valencia, an opinion which I am fully able to endorse. I had always thought it a fitting companion for that popular sort Miss Jolliffe in point of habit and floriferousness, but it possesses greater vigour, and bears larger blooms. Mr. Dunkin says some of the most beautiful of the varieties bloom but little until the spring months, a point I do not quite agree with him in, as I believe this failing might be overcome by early propagation and good treatment. I have for several years grown these plants for producing flowers through the winter months, and out of the several varieties cultivated I know of none that failed to bloom until spring, and I find that not only are they appreciated from now onwards till Christmas, but if procurable all the year round for buttonhole purposes.

The secret lies in early propagation, as Mr. Dunkin advises, selecting strong side shoots if possible during February. If the plants are grown in a light and airy structure the cuttings root readily at this period, while on the other hand, if they are crowded thickly and shaded by other plants, the growths are weak, long jointed, and soft, and are sure to collapse under the confined treatment required for striking. This fact at once creates necessity for a later "strike," and thus valuable time is lost. We have plants which are now blooming treated as above that have been standing outdoors since the beginning of July in a sunny position, and from some old plants we have gathered blooms daily for several months, and yet they bid fair to continue throughout the winter.

Unfortunately many of the strong-growing sorts produce "grass" so very sparingly that unless numbers of plants are grown propagation is of necessity slow, and a few older plants may well be retained for stock purposes, and it may be said that although the individual blooms are smaller they are given with greater freedom than from younger plants. I have had from two to three dozen blooms expanded at one time from plants in 6-inch and 7-inch pots, proving that large pots are unnecessary if the plants are liberally treated with manure in liquid form. Jensen's fish

manures appear to suit them admirably, either as a top-dressing or in a diluted state, as I have noticed when these manures were exclusively applied the plants assumed an unusual vigour. The following are among the best I have grown—viz., Col. Cox, bright scarlet, large bloom; Coronet, deep scarlet; Mrs. Oldacre, bright rose; Bright Phoebus, a great favourite, the blooms large, of good shape, and the colour intense, vigorous, but of dwarf habit; Gipsy, dark crimson, good; Laura, pink, a pretty fringed flower; Worthington Smith, scarlet; Brunette, maroon, distinct; Sir Charles Wilson, rose large fringed bloom; Incomparable, a magnificent flower, but the habit of the plant too stiff, and grows very tall; Belle Rose, an old yet valuable sort, and beautifully scented.—W. S., Frome.

IN THE GARDEN OF ENGLAND.

By common consent and general acceptance this term applies to the fertile and fruitful county of Kent. If there is one part of Kent more famed than another for the production of fruit trees it is Allington, near Maidstone; and if there is one Kentish name more familiar than another to fruit growers, it is that of Bunyard. The "Old Nurseries," Maidstone, the head-quarters of the firm of Messrs. George Bunyard and Co., were established upwards of ninety years ago, and for three generations the trade was general and local. It is general and local yet, but far larger "round home" than ever it was before; and in addition to that, one particular branch has become in the widest sense of the term national—the trade in fruit trees. This great extension is the direct result of the technical skill, energy, and enterprise of the present chief of the establishment—or it might, perhaps, be said proprietor, for it does not seem easy to trace the "Co." beyond the experienced co-workers, or heads of departments, in the different branches of the business. Mr. George Bunyard has done a great work in the course of twenty years to have acquired such an extent of land, stocked as it is stocked to-day, and won for himself a name that is so widely known in the domain of horticulture. How he has done it none but himself can tell, but it could not have been accomplished if he had not been a devoted lover of fruit, a good judge of procedure, and a pertinacious worker in that which he set himself to do.

The home nursery is in the town, near the South-Eastern Railway station. The site has been acquired by purchase and handsome premises built. There are other places of business in the town, and adjacent thereto a considerable extent of land devoted to general stock, but the great manufactory of fruit trees is one or two miles in the opposite direction—Allington. Now if anyone wishes to go direct to the fruit trees by rail from London he must not "book" to Allington, because there is no station of that name, nor to Maidstone, as there is the road journey indicated, but to Barming. Another thing, if an intending visitor wishes to ascertain by telegraph a convenient day and time to arrive, he must not think the address of "Bunyard, Maidstone," will suffice, for a message so addressed will not be delivered. This the writer learned from experience, then a few days afterwards found a notification in the very last corner of the catalogue, stating the fact, and informing those who turn over the pages to the end that telegrams must be addressed "George" Bunyard; there is no "Co." there, but presumably more Bunyards at Maidstone. If I were "George" I should have the very useful information to visitors on the first or second pages of the work, for a "work" it is, and not a mere list of names and prices, but for some occult reason he does not commence "paging" till he reaches "5," and with that figure he begins, though most persons begin with "1." In the examination of a witness in a trial case on the stage he is asked his age by the judge. "Thirty-five, my lord" is the reply, quickly adding, "I should be thirty-seven, but I have been laid up for two years." Mr. Bunyard has not been "laid up," or he would not have done what he has, but his printers have been giving the first four numerals a rest. The reader, however, loses nothing, but may obtain much information for 6d., and as many trees as he likes, or as his purse allows, up to 400,000. The Allington Nursery alone comprises 76 acres.

Arriving at Barming station, on the London, Chatham and Dover railway, the visitor may be among the trees in two minutes, for he has only to ascend half a dozen steps and he will be in the nursery. To the right and the left he will see a forest of trees, and as he passes along to higher ground still another forest ahead of him. From the vantage ground he will also see a beautiful and breezy country, open to all the winds that blow, with a stiff keen rush now and then between the hills from the German Ocean. The conditions then are present for ripening the growth that is produced by the not "fat" but fertile soil. It is fruit tree soil beyond a doubt, and the best is made of it by free working. The scuffle is always at work in favourable weather between the rows, horse and man moving briskly, as if they enjoyed the whisking of the branches. The man is not muzzled, so it seems he can be trusted among the fruit, for there is no lack of this on some of the young trees; but the horse has to submit to the same treatment as the London dogs, and if not muzzled he would probably do more pruning than the master approved. Mr. Bunyard does not believe in weeds, and though it must be costly keeping them in subjection, it is more costly still leaving them alone to eat the virtues out of the soil that the trees require. The growth they make would satisfy the most exacting, and it is largely due to the surface-stirring, though not wholly. The land no doubt contains potash, and that is what fruit trees like. If this mineral did not

abound in the district the pastures would not be so full of Clover, and the trees could not grow so well. They are strong without frothiness, and extremely stout in the foliage. Neither blight nor canker can be seen in a ten mile walk along the paths between them. Most interesting it is to walk down a 20 acre piece of yearling Apples, the first growth from the bud, and to note the evenness of the varieties and the character of each in foliage and relative vigour; some rows strong and stately, others of medium stature; some with broad dark leaves, others lighter and pointed. A rogue in any of these rows would be "spotted" in a moment. Keen-eyed experts like Mr. Bunyard and his men know the varieties of fruits by their leaves and wood a great deal better than thousands of persons who purchase and plant know them by their fruit; yet all are either plainly named or numbered, the old hieroglyphical crosses and notches being abandoned; it is therefore not possible to see how mistakes in nomenclature can occur. Then follow forest-like masses of two-year-olds, in which the habits of the varieties are displayed, upright or spreading, precocious or otherwise in forming fruit buds. The contrast in those respects is very striking between, for instance, the sturdy and bristling Lane's Prince Albert and the quicker-growing and slower-bearing Blenheim Orange.

The stock of Apples we are told numbers 100,000, and judging by the extent of land occupied by the trees the visitor would conclude there are more. Among the newer sorts, freely bearing on young trees—an excellent indication of coming usefulness—Bismarck is prominent by its large red fruit. This Australian Apple was first exhibited by Messrs. Veitch & Sons, and certificated at the Crystal Palace. It has often been represented by orchard house fruit at shows, and not a few admirers have concluded the variety is not hardy enough for our climate, but no Apple bears handsome fruit more freely than this does in the open quarters at Allington, and Bismarck can scarcely fail to become a favourite in the market. Belle Pontoise also bears large, flattish, and most attractive fruit very freely. As a market sort *par excellence* Mr. Bunyard places the new variety Royal Jubilee quite in the front rank. The young trees bristle with fruit buds, and the golden conical fruit is tempting in appearance, and though ready for use early keeps a long time. Lady Sudeley (originally Jacob's Strawberry) is in great force, and sure to be extensively planted when its merits are fully recognised. Freedom of cropping, richness of colour, and good quality are its characteristics. It will probably be seen in piles on fruit stalls and costermongers' barrows in a few years time, than which there is no better test of usefulness. Wealthy, an American variety, bears highly coloured fruit abundantly, and thus recommends itself. Mr. Bunyard regards Newton Wonder with much favour as a valuable late keeping Apple. Laxton's September Beauty is noticeable by its glossy red fruit, and the certificate it won is evidence of value. Baumann's Red Winter Reinette bears heavily dark crimson fruit, and is a distinct variety of great promise. The Scarlet Costard and Gascoyne's Scarlet are highly coloured, while Hornead's Pearmain is highly regarded in the nursery. Of better known kinds bearing freely, among many sorts that are barren, are Pott's Seedling, Lord Grosvenor, Ringer, Worcester Pearmain, Duchess of Oldenburgh, Stirling Castle, Grenadier, Lord Derby, Lane's Prince Albert, Brownlee's Russet, Cox's Orange Pippin, Improved Kerry Pippin, Hubbard's Pearmain, and Scarlet Nonpareil, all good varieties, and Bramley's Seedling is in great demand for orchards. All forms of trees are grown on different stocks, including standards on a good form of the Paradise, covered with fruit all up the stems like "ropes of Onions"—favourites with owners of small gardens. Several Apples are grown in pots, and bearing splendid fruit in the orchard house.

Pears are not grown so extensively as Apples, yet there are 50,000 of them. Rivers' Fertility is taking the lead among orchard standards, and for the same purpose Beurré Bosc, Clapp's Favourite, Pitmaston Duchess, Hesse, Beurré de Capiaumont, Crawford and Lammas are in great demand. For garden culture as pyramids, cordons and espaliers, those bearing the most freely this (unfruitful) year are Beurré d'Amanlis, Durondeau, Duchesse d'Angoulême, Fondante de Cuerné, Emile d'Heyst, Maréchal de Cour, Louise Bonne of Jersey, and Marie Louise d'Uccle. Particularly fine in the orchard house are Pitmaston Duchess, Beurré Diel, and Doyenné du Comice. Among the less known varieties Aspasia Aucourt, Buerré Baltet père, and Fondante Thirriott are thought highly of at Maidstone.

Now we pass to Plums. There are acres of trees, the number being 150,000, and 60,000 Damsons. Victoria leads the way for usefulness, but the Czar and Kentish Bush Plums have to be grown by the thousand, all the choice garden varieties being provided in proportion to the demand. Rivers' Monarch, Cox's Emperor, The Sultan, Grand Duke (fine late), and the Gages are evidently required in considerable numbers and are good. The Farleigh is the chief Damson (40,000 trees), and next to it the Shropshire or Prune for market purposes.

As may be expected in the great Cherry county trees of the different varieties have to be extensively provided. There are acres of fine standards on tall stems, while pyramid, trained, cordon, and orchard house trees are represented in the leading varieties, but the Bigarreus appear to predominate in the stock of 50,000.

Peaches, Nectarines, Apricots under glass and outdoors in the form of trained trees of various heights and shapes, also as bushes or pyramids, are provided in great numbers, 10,000 or more; the Gladstone and Waterloo Peaches are increasing in demand yearly as their merits become recognised. Of the older Peaches Royal George remains the greatest popular favourite. Figs are grown in pots somewhat extensively, also Vines, and Medlars, Quinces, Mulberries, and all sorts of bush fruits have place in the emporium.

Long marginal borders of choice Conifers, the bluish Cupressus Lawsoniana Alumni being conspicuous, alongside the grassy promenades add a feature of interest, and in the summer and through the autumn large squares of Roses afford blooms for all comers and more than they can take away. Roses on their own roots grow here quite as well as on any stocks, if not better. The free flowering China Rose Louis Phillipe appears to be a feature, and the plants are laden with blooms till winter. Spiraea Bumaldi one of the dwarfest and most attractive of the family, is extensively grown for border decoration, and is highly worthy of cultivation.

The span-roofed orchard house, 100 feet by 30 feet, contained three rows of Peach and Nectarine trees down the centre, trained "riders" of various heights and ready for bearing at once, the sides being occupied with Apples and Pears in pots bearing "exhibition" fruit. A house of the true Rollisson's Telegraph Cucumbers was bearing its third crop; the fruit 20 to 26 inches long ripening for seed, and 1 Donald Beaton's outdoor Ridge Cucumbers, which is quite one of the best, was being harvested. Tomatoes on banks are well worthy of mention, the growths trained to sticks or wires about 18 inches above and parallel to the ground being roped with fruit, Laxton's Open Air the favourite variety.

Very interesting, also instructive, is it to spend an hour in an establishment such as this with one of the recognised masters in the art of hardy fruit culture, not an "old" master, but in the prime of life, with still, it is hoped, a long future before him. The telephone connects Allington with the head quarters in Maidstone, and in erecting offices for the transaction of business in the nursery the men have not been forgotten. The necessary provision for their comfort has been made during the periodical rests, and they no doubt work the more actively between them, for workmen worthy of being employed are appreciative and study the interest of those who show themselves well disposed towards them.

Some reference ought to be made to an adjacent fruit garden planted by Mr. Bunyard about seven years ago on the estate of Mr. Brassey—to the heavily laden Queen Caroline, Lord Derby, and other profitable Apples, and the bush fruits below, which alone have been handsomely remunerative; but more space must not be encroached on, interesting as the record might be, and Mr. Bunyard is thanked for his kind attention to a sudden caller at his nurseries.—F. R. H. S.

BLACK HAMBURGH GRAPES AT DRUMLANRIG.

YOUR correspondent "A Kitchen Gardener," who has lately visited Drumlarnig Gardens, seems astonished at the grand bunches of Black Hamburgh Grapes he saw there; and no wonder, when he informs us, "According to some authorities the cultivation of old fashioned high class Black Hamburgh Grapes," mark you—"is almost a lost or unknown art," and he verily "believes there is some truth in their assertion. In fact," he writes, "I know instances where the Black Hamburgh was discarded to give place to more showy varieties." This, I am sure, is news that few gardeners will be prepared to receive, let alone credit.

Oh! ye degenerate sons of Adam, "A Kitchen Gardener" must wake you up and teach you the lost art of growing "old fashioned high class Black Hamburgh Grapes." I know that Mr. Thomson's Grapes are first rate examples of the variety in question, and are well worth going a long way to see. But it is a calumny on gardeners to say that the art is lost, or the Grape in question is neglected or discarded on that account. I believe if a census was taken of all the establishments in the country where Grapes are grown, it would be found that there were not six places in the kingdom where the Black Hamburgh was left out of a collection. I am curious to know what some of our great horticultural teachers will have to say on the subject, and more especially Mr. Muir of Margam, who, we have been told, has grown Black Hamburgh Grapes to something like perfection without the aid of fire heat, in the climate of South Wales.—FIFESHIRE.

HORTICULTURAL CLUB.

THE first monthly dinner and conversazione for the session 1899-90 took place at the Club rooms, Hotel Windsor, Victoria Street, Westminster, on Tuesday evening. The Rev. W. Wilks, in the absence of Mr. John Lee, occupied the chair; and there were present the Rev. F. H. Gall, Messrs. Girdlestone, H. J. Veitch, H. J. Pearson, George Paul, J. H. Veitch, T. B. Hall, T. Francis Rivers, James Walker, Geo. Prince, A. Prince. The Very Rev. the Dean of Rochester; W. Herbert Fowler, Esq., Claremont, Taunton; and J. H. Stott, Esq., The Lindens, Preston, were elected members.

The subject for discussion was "The Dressing of Roses," which was introduced by Mr. T. W. Girdlestone, who stated that the subject had only very recently cropped up, and it was, he believed, practised mainly amongst northern growers, and was not much adopted amongst amateurs. He said that in all florists' flowers there was a certain amount of manipulation practised by which petals were brought into position, and a flower made to appear somewhat larger than it otherwise would; but what he alluded to was a practice by which the whole character of the flower was altered, as, for instance, where a high pointed centre, as in Alfred Colomb, was so manipulated by having its petals turned inside out as to appear like A. K. Williams, or where a small bud of a Tea Rose, not an inch across, was so opened out as to make a flower some 2 or 3 inches across, entirely altering its character.

He strongly objected to this, not only because it spoiled the beauty of the flower, but also because it gave the public a false notion concerning them. They see these flowers, named, in the stands; they order them, and are very much surprised and disappointed to find them entirely different in their gardens. He did not know to what extent it had gone, but he had seen at the Crystal Palace Show a box of Teas so manipulated that it was hardly possible to recognise the flowers, and he therefore thought the time was come to pronounce decidedly against it. The National Rose Society had carefully watched over the interests of the flower and everything connected with it, and he believed that the Committee of the Society could put its foot down on a practice which he believed to be most hurtful to the cultivation of the flower. A very interesting discussion followed, in which several of those present took part. Mr. George Paul stated that he believed whenever this excessive dressing took place in any flower, it tended to its going out of favour. Take, for instance, the Carnation. This was once a favourite garden flower, but when exhibitors so dealt with it that its character was entirely altered it went out of favour, and so at the present there are a few who grow it and exhibit, but it is the self and border varieties that are now becoming popular—flowers that need not be dressed, but allowed to grow naturally; and so he believed it would be with the Rose, although it would be difficult to drive that out of favour; but there was danger, unless the practice were stopped, of these grand flowers being neglected. Mr. T. Francis Rivers said he could hardly believe it possible that an exhibitor could dress a stand of seventy-twins in the time allotted to him after he had placed his flowers in the box, he seemed to advocate the cultivation of garden Roses, and spoke quite enthusiastically of Roses which he had 20 feet high, clambering over some old Pear trees and regularly festooned with flowers.

Mr. T. B. Hall said that he had often watched with pleasure and some degree of envy a well known exhibitor going over his box of Roses before the judges came round, but in these was nothing unfair, the character of the Rose was not altered, but only a little additional charm given to it in its natural character. Mr. Harry J. Veitch alluded to what had taken place with regard to the exhibition of Orchids. They were not dressed certainly, but where prizes were offered for say six Orchids the custom grew of placing a large number of small plants in a huge pan filled with small plants, and then it became necessary to make two classes—one for plants naturally grown as single specimens, and one for the "made up" exhibits. The Rev. H. H. D'Ombra as Hon. Secretary of the National Rose Society said he was sure that the wish of the Committee would be to utterly discountenance this injurious practice by giving instructions to the judges; and he believed that the best way would be to pass by all such flowers as if they were not exhibited; and as it had been with gumming, so with this, he believed that we should have no more of it, and he was quite sure that the discussion would greatly strengthen the hands of the Society in dealing with the practice. After several other members had spoken Mr. Wilks proposed a cordial vote of thanks to Mr. Girdlestone, and a very pleasant evening was brought to a close.

PEACHES.

FEROUS SULPHATE FOR "YELLOWs."

I GLADLY comply with the request of Mr. T. Welch, page 311, in telling him through the medium of the Journal how I cured the Peach tree mentioned by Mr. Wright. It is only fair to say I was led to try this remedy through reading an account of some experiments by Sachs, written by Mr. G. H. Marshall Ward in the *Gardeners' Chronicle* for April 13th, 1889.

One of our Peach trees, a Princess of Wales, was badly attacked with "yellows" this spring, owing, as I believe, principally through a severe check in November, 1887, when lifted for the purpose of draining the border, &c., followed by a bad season in 1888 for maturing the wood. The house was started December 1st, 1888. The sulphate was applied early in May by removing the soil over the greater part of the roots without injuring them. Three-quarters of a pound was then dissolved in a little hot water, and enough cold water was added to make about 10 gallons in all. This was poured over the roots, and a similar quantity of clear water was then put on to wash it in; the soil was in a previously moist state from a recent watering. After this the top soil was returned again as before, and in a short time a considerable improvement was apparent, and eventually the tree completely recovered. That is how we cured our tree. It does not necessarily follow that all cases of "yellows" can be cured in the same way. The above tree was growing in a well heated house, and in a thoroughly well drained border. I am of opinion that "yellows" is caused in many instances by the roots getting in an unhealthy state from bad drainage and similar causes. Ferrous sulphate will be of no avail in such cases until these defects are remedied. Mr. Welch says he will partly lift his trees soon; if he thinks the drainage or border is bad he will do well to lift them entirely and make everything right. If carefully done and replanted as soon as possible no harm will befall the next crop in consequence, provided the trees are started gradually, and not pushed into growth beyond what the roots can maintain. It is easy to see when the roots are beginning to grow freely by the corresponding advance in the young growth. I have often lifted trees that had not been disturbed for years, and have sent some of them long distances by rail, and find the Peach and Nectarine will bear removing and lifting far better than most people would imagine.

I would not advise your correspondent to plant Lord Palmerston

Peach; its great size is its only recommendation, its quality is poor in the extreme. Princess of Wales, which is one of its parents, is far preferable and ripens about the same time. Another good late variety is the Nectarine Peach. I am unable to give any opinion on Reine des Vergers.—W. H. DIVERS, *Ketton Hall Gardens, Stamford.*

I KNOW nothing of Peach Reine des Vergers, but would strongly advise Mr. Welch not to invest in Lord Palmerston. We are just about to destroy a rather large tree of it which has never given a fruit fit for dessert, and we consider a south wall too valuable for growing Peaches for any other purpose. Lord Palmerston is only a few days later than Walburton, but bears no comparison with that variety.—E. BUTTS, *Leigham Court Gardens, Streatham Hill.*

NATIONAL CHRYSANTHEMUM SOCIETY.

A MEETING of the Floral Committee of the above Society was held in the Royal Aquarium, Westminster, on October 9th at 2 P.M., when the following members were present—E. Sanderson, Esq., in the chair, Messrs. W. Holmes, R. Dean, J. P. Kendall, G. Gordon, L. Castle, R. Owen, C. Swift, J. Mardlin, G. Stevens, T. Bevan, H. Cannell, J. Wright, and C. H. Payne. Messrs. H. Cannell & Sons, Swanley, had an interesting collection of fine Chrysanthemum blooms, for which a vote of thanks was accorded. Mr. R. Owen, Maidenhead, also exhibited several varieties. Messrs. Hawkins & Bennett, Twickenham, had a stand of twelve handsome blooms of Chrysanthemum Mrs. Hawkins (vote of thanks); and Mr. G. Stevens, Putney, also contributed cut blooms. Messrs. Cannell & Sons showed blooms of a Japanese variety named *Meto*, with white irregularly cut florets faintly tinged with red. The bloom was somewhat flat, but appeared to be distinct, and the Committee expressed a wish to see it again at a later meeting.

A plant of a Japanese Chrysanthemum (unnamed) was sent by Mr. Briscoe Ironsides, Fooks Cray, which was said to have been raised from a single leaf without any bud or portion of the old stem being attached. The leaf was inserted in a thumb pot on January 20th, and potted into a 60-size pot in the first week of April, and from a sucker produced at the base the plant had resulted. It had a strong stem 2 feet high with abundant foliage, a number of suckers at the base, and one large flower at the apex of the stem. It was stated that other leaves had been rooted but discarded, as the one specimen was sufficient for experimental purposes. A vote of thanks was accorded to Mr. Ironsides for his interesting communication. Only one certificate was awarded—namely, for the variety,

Jeanne Marty (R. Owen).—This is a Japanese Anemone, one of Audiguier's varieties sent out in 1886, but although it has appeared in a few exhibitors' collections it is not by any means well known. It was, however, included in the National Society's Catalogue of Select Varieties for 1888, and is thus described:—"Blush white, dropping guard florets, lilac disc, large, with full high centre; midseason, rather tall."

A MEETING of the National Society's General Committee was held in Anderton's Hotel, Fleet Street, on Monday, October 14th, at 7 P.M., E. C. Jukes, Esq., in the chair, when there was a large attendance of members, and a considerable amount of important business was transacted. Mr. Holmes read the minutes of the last meeting, which were duly confirmed, and he then referred to some correspondence he had had with the officials of a new Society in Philadelphia, who required some rules to guide them, and had adopted those of the National Society as a suitable foundation. The subject of the medals was next considered, and samples from two firms having been submitted, it was subsequently resolved, on the motion of Mr. Rundell, seconded by Mr. Prickett, that the order be given to Messrs. Restall.

The Hon. Secretary referred to the Chrysanthemum Centenary Celebration to be held at Ghent, and mentioned that several members of the National Committee had been appointed judges, a compliment to the Society which ought to be appreciated. At a later stage of the proceedings the Chairman proposed that the members of the Committee who had been requested to act as judges at Ghent be officially appointed a deputation from the National Society, and after some discussion approving of this course, it was adopted unanimously. Mr. C. Harman Payne also referred to some correspondence which had taken place between himself and the Ghent officials, who were very desirous of having English exhibits and exhibitors at their Show. Mr. Payne stated that he had been in communication with the National Chrysanthemum Society of the United States, and some important help was likely to be rendered in the determination of the names and synonyms of American varieties. Three members were proposed to fill a vacancy in the General Committee caused by the retirement of Mr. Gilbey, who has removed to the north of England, and is consequently unable to attend the meetings. Mr. Briscoe Ironsides was ultimately elected, and Mr.

Boyce was similarly elected on the Floral Committee. Mr. G. Gordon next reported that Mr. L. Castle, Mr. Payne, and himself had, in accordance with instructions of the General Committee, prepared a supplement to the catalogue including the best of last year's varieties, and it is now published.

Mr. Holmes reported with regard to the Provincial Show at Hull that he had lately visited the officials there and satisfactorily arranged all the details. He considered the buildings amply large enough for a first-rate show, and he mentioned that arrangements were being made for a Conference that was likely to prove of an exceedingly interesting character. Mr. E. C. Jukes would preside, and Mr. J. Wright with Mr. G. Gordon would contribute papers, and the mention of their names was a sufficient guarantee that the subjects would be thoroughly well treated. Entries for competition could be made through Mr. Holmes up to within three days of the Show, in compliance with the National Society's rule, but the Hull Society required a week's notice of entry. It was proposed that the 5.45 P.M. train to Hull on November 20th would be a convenient one for those intending to visit the Show, and if he received sufficient notices from members and visitors he could engage a saloon carriage, as on the occasion of the Sheffield Show last year. He further suggested that the members of the Floral Committee who may be present at the Hull Show as judges or visitors might be authorised to deal with any new varieties there exhibited, and to make awards in the same way as in London. This was formally proposed, seconded, and carried.

In reply to some questions asked respecting the November Show at the Westminster Aquarium, it was explained that it is not at all likely the music licence will be withheld, and even if it were they would still be able to hold flower shows and similar gatherings. Some proposals were made with regard to entertaining the Floral Committee at lunch on the occasion of the November Show, and as that is a very busy day it was decided that a complimentary meeting and lunch should be held on December 11th. After the election of several members, bringing up the total to 626, the amateur question cropped up again, the Hon. Secretary having received a letter from one intending exhibitor, who had been away for three weeks, and employed a man in the meantime to water the plants. Another had been away for six weeks, and similarly engaged assistance in his absence. It was resolved that the Hon. Secretary should be empowered to determine in cases of this kind whether a person was entitled to exhibit as an amateur or not, as it was impossible to frame a rule to meet all cases. The usual vote of thanks was accorded to the Chairman, and the meeting concluded about 9 P.M.

CHRYSANthemum CONFERENCE, CHISWICK.

NOVEMBER 5TH AND 6TH, 1889.

At a meeting of the Royal Horticultural Society's Executive Committee, October 8th, 1889, there were present Mr. Shirley Hibberd (in the chair), R. F. Jameson, L. Castle, C. E. Pearson, J. Douglas, N. Davis, C. Paul, N. Holmes, W. Wilks, T. B. Haywood, H. J. Veitch, J. Wright, C. Orchard, and W. Wildsmith.

The Chairman suggested that the Exhibition should comprehend six groups of subjects, and that these should be examined by committees of selection, who would award certificates of merit to the best varieties in each group on the plan of operations at the late Vegetable Conference. The foregoing being agreed to, groups and Committees were arranged as follows:—

(a) Varieties adapted for garden decoration. Committee: Messrs. H. Cannell, W. Wildsmith, H. M. Pollett.

(b) Varieties incurred for specimen blooms. Committee: Messrs. J. Wright, D. Donald, W. Mease.

(c) Varieties of Japanese for specimen blooms. Committee: Messrs. W. Holmes, E. Wills, R. F. Jameson.

(d) Reflexed, Anemone, Pompon, Pompon-Anemone, and single varieties for cut blooms. Committee: Messrs. C. Orchard, L. Castle, N. Davis.

(e) Varieties of all classes for trained specimen plants. Committee: Messrs. E. Beckett, E. Berry, J. Laing.

(f) Varieties of all classes for decorative plants. Committee: Messrs. C. Herrin, R. Owen, W. Furze.

Referees: Messrs. H. J. Veitch (Chairman), F. W. Burbidge, J. Doughty, R. Parker, J. Lyne, E. Molyneux (Secretary of the Conference), C. H. Payne, and W. Piercy.

It was finally arranged that the Executive Committee and Committees of Selection should meet in the vinery at Chiswick at 11 A.M. on November 5th.

BIRMINGHAM CHRYSANthemum SOCIETY.

THIS Society have determined to celebrate the centenary of the Chrysanthemum in a most liberal manner. The Show takes place in the Town Hall, Wednesday and Thursday, November 20th and 21st, and for forty-eight cut blooms, twenty-four incurved and twenty-four Japanese, the substantial prizes of £25 for the first, £15 for the second, £7 for the third, £4 for the fourth, £2 for the fifth, 30s. for the sixth—a total of £54 10s., the greatest amount ever provided in one class, and ought to induce a strong competition among the leading cultivators.—URBANUS.

LEEDS PAXTON SOCIETY.

WE are informed that a Chrysanthemum Show under the auspices of this Society will be held in the Town Hall, Leeds, on November 12th and 13th, and that good prizes will be offered for cut blooms, but we

have not yet received a schedule. Mr. T. Bonsall, Elmet Hall Gardens, is the Secretary.

TEDWORTH GARDENS, WILTS.

VISITING this secluded and picturesque part of Wilts, and having heard many speak in praise of the Tedworth Gardens, the residence of Sir J. Kelk, Bart., our curiosity was gratified by a cordial invite from Mr. G. Inglefield, the head gardener, to inspect the same. Accordingly, on a fine morning in this beautiful autumn weather we found ourselves at Ludgershall station and the garden cart awaiting our arrival. The drive to Tedworth is about three miles up and over the Wiltshire Downs, commanding on all sides splendid views of the surrounding well-wooded country. On entering the park by the main lodge gates we proceeded up a long avenue of thriving Limes, which, though only planted eight years ago, already give welcome shade and are getting arched overhead. Turning to the right we were met by the genial gardener, who conducted us to the gardens. The first noticeable feature was the Chrysanthemums staged in the framing yard to the number of about 600. These we found to embrace most of the well known varieties. We noticed Avalanche, Violet Tomlin, Mrs. F. Jameson, E. Molyneux, W. G. Drover, Madame Baco, &c. All the plants were in the best of health, strong wood well ripening, the foliage presenting that healthy though leathery appearance so much sought after by the best growers. We do not imagine Mr. Inglefield need fear to compete with the leading exhibitors if, as seems probable, his plants continue in their thriving condition. Entering the walled-in gardens, some two acres in extent, we passed through the vineries, finding houses for the culture of Muscat, Black Hamburgh, Gros Colman, and other Grapes. Fruit culture under glass is evidently a specialty. The bunches of Muscats were the largest seen by us this season. In the Peach houses the late sorts were a prolific, fine shaped, and well coloured crop. The last house in this range we found stocked with pot Figs giving promise of an abundant crop for next season. The stove house next claimed our attention, and contained well coloured Crotons and Dracenas; also healthy young Palms, with a good assortment of tropical plants. The fernery was well stocked, Adiantum farleyense being especially noticeable. The Begonia house elicited our warmest admiration, containing as it did a splendid assortment of the best double and single varieties; some of the latter Mr. Inglefield planted out in four large beds in front of the mansion and they looked superb. The next house contained a fine collection of Orchids. In the large Camellia house we found thriving specimens from 8 to 10 feet high with glossy foliage and well set with buds. A very large Rose house contains standards in the centre of the best sorts, and springing from the sides well overhead Maréchal Niels, &c. The remaining portion of the kitchen gardens presented a neat appearance. On the fine lawn fronting the mansion are dotted specimen Conifers, and several carpet beds attract attention. The area of the estate, we were informed, is 7000 acres. On returning to the gardener's house we observed that, besides, potting sheds, offices, &c., were amply provided. Then after partaking of the hospitality of our host and hostess the gardener's cart again safely conveyed us to Ludgershall station, whence we departed by train for fresh fields and pastures new, fully satisfied, however, it would be some time ere we should have the pleasure of viewing the equal of Tedworth.—TWO JOLLY GARDENERS.

NICOTIANA AFFINIS, LONGIFLORA, OR PERSICA?

IN perusing the "Floricultural Cabinet" for 1833, I came across two notices given there of a Nicotiana, which struck me from the descriptions as bearing a very close resemblance to the plant now so popularly known as Nicotiana affinis, and brought prominently before the public under that name a few years since. I trust it will not be deemed out of place here to quote the full extracts given in the above work. The first is an extract of the description of a plant figured in Edwards' "Botanical Register" for June, 1833, edited by Dr. Lindley. "Nicotiana persica, Shiraz Tobacco.—It is rather a handsome annual, exhaling a faint but pleasant odour in the evening, at which time its flowers are in perfection. In Persia it grows 3 or 4 feet high. Flowers: Petals, white inside, green outside. Culture: It requires a dark, rich soil, and most abundant watering during all the season of heat." The second notice is an extract from Sweet's "British Flower Garden" for the same month, June, 1833, edited by D. Don, librarian to the Linnean Society, and reads thus:—"Nicotiana longiflora, Long-flowered Tobacco.—This plant is a half-hardy annual, thriving best in light rich soil, and is increased by seeds. It is a native of Buenos Ayres, where it was discovered by Mr. Tweddie."

Up to this point, from the above descriptions, it does appear there were two distinct varieties, although it must be observed that the colour of the flowers of N. longiflora is not described. In October of the same year there is an article in the same journal on the "Treatment of Nicotiana longiflora, Long-flowered Tobacco," and the writer there said, "That in the first week in May he turned out six plants into the open border under a south-aspected wall; the soil of the border is annually enriched during winter or spring with leaf mould and well rotted cow dung. The plants soon took advantage of the new situation, and by the end of July each was 4 feet high, and spread proportionally, producing hundreds of pure white flowers at the same time. They are slightly fragrant. When the sun is powerful the blossoms close up for almost three hours about the middle of the day, but during the other part are fully expanded, and towards evening the plant has a most beautiful

appearance." It does appear singular that there should be figured in two distinct journals in the same month and year two plants answering to the character of the plant now known as *N. affinis*, and then an article appearing only four months afterwards further describing *N. longiflora*, all of which descriptions give me a suspicion that there existed only one variety at that time, but under two names, and, if not? one is lost while the other has been brought prominently forward, and become a general favourite amongst us after the lapse of half a century. *N. affinis* has long terminal tubes which would not be misnamed if known as *longiflora*. It is also sweetly scented, and only expands of an evening or early morning, closing up during sunshine after the manner of the plants described in the works named for 1833.

I have not the facilities for pursuing this subject farther, but some of your readers may be able to compare *N. affinis* of to-day with the original figures of 1833, of *persica* and *longiflora*.—J. W. MOORMAN.

CACTUS DAHLIAS.

WE grew long rows of these this season, many more plants than formerly, and nothing in the open has proved so attractive or serviceable. All are more or less abundant flowering, and whole basketfuls could be cut, towards the end of the season especially, without detracting much from the appearance of the plants. For large vases and church decorating purposes these Dahlias are of the greatest value, and probably have been more extensively and generally used this season than at any previous time. Compared with the Cactus varieties so called, the single Dahlias are deficient in merit, and it is surprising how rapidly the latter have lost ground in public estimation. At the present time (October 3rd) the good old Constance is perhaps the most useful, this variety invariably flowering very freely, the blooms also being more nearly pure white than earlier in the season, cooler weather evidently best suiting it. Henry Patrick we were led to believe will soon supersede Constance, and it is certainly an improvement on it, the flowers being more freely produced, especially in the early part of the season. They are of good form and pure white. Altogether it is a most desirable variety, and invaluable to wreath makers. A. W. Tait grows taller than either of the foregoing, and is free flowering. The blooms are moderately double, with finely cut or fimbriated florets, the colour being pure white. Mrs. Hawkins is the greatest favourite of all with the ladies. It is of moderate height, very floriferous, the individual blooms being large, not too double, of good form, and of two shades of colour—viz., sulphur yellow suffused with pink. We cut this with plenty of foliage and buds, large branches looking grand in conjunction with sprays of well coloured Virginian Creeper, whether in vases or laid on a dining table. Henry Patrick is also very attractive, the colour being a rich yellow. It is of medium height, free flowering, the blooms being borne on long footstalks. This is one of my favourites.

Empress of India will become as popular as any of the foregoing. It produces extra fine, well formed flowers of a very dark crimson colour. Juarez is known to all lovers of border flowers, this being the true Cactus Dahlia, and distinct in form from any of the preceding. Other colours in this type are now to be had, and these will, I trust, be grown by me next season. Glare of the Garden we find more free flowering than any of those already named, the blooms also being much smaller, in colour a rich scarlet. It is of comparatively dwarf habit, and one of the best to cut from. Crimson Glare of the Garden is of similar habit, but the colour is darker, and an improvement on this will be found in Cochineal. The last named is exceptionally showy and fine for massing. We frequently cut large branches for vases, and it is most effective. Lady Dyke proves to be more of a semi-double than any I have named; it is distinct, of medium height, and free flowering, the blooms being borne on long footstalks, and therefore excellent for cutting. The florets are white, edged with scarlet.—W. I.

HARDY FRUIT SHOW.

CRYSTAL PALACE.—OCTOBER 10TH, 11TH, AND 12TH.

A SEASON so variable as the present, and so unfavourable in some districts to Apples and Pears, might be expected to result in an unsatisfactory Exhibition; but so far from this being the case, the Show held on Thursday, Friday, and Saturday last will compare very favourably with any held in previous years. In numbers and quality the Apples especially were all that could be desired, and in the first of the open classes alone about 700 dishes were staged, constituting an array of bright and diversely coloured specimens such as are rarely seen in competition. As regards exceptional size and merit the Barham Court Apples were, however, supreme, and we do not remember having seen a finer collection of two dozen varieties than that which obtained leading honours in the amateurs' division. Pears were good, those from the garden named above being again much the best, but these classes are never so attractive, from an exhibition point of view, as the Apples. It has frequently been remarked that it would be much more satisfactory if separate classes were provided for orchard house fruits, as when these are shown in collections of fruit grown outdoors or in competition with them the comparison is unfair and misleading. This was still more noticeable at the Show under review, and it is quite likely that an alteration will be made another season.

Vegetables constituted an important portion of the Exhibition, the samples staged being in nearly every case remarkable for their freshness and good culture. Miscellaneous non-competing exhibits were numerous and interesting as usual, adding considerably to the attractions of the

Show. A large proportion of the space in the north nave was occupied with the various products staged, and Mr. W. G. Head arranged them effectively on tables, with groups of Chrysanthemums, Palms, Ferns, &c., between.

In the afternoon of the first day the British Fruit Growers' Association held a meeting and conference, particulars of which appear on page 327.

The chief class for Apples was that (open to all exhibitors) in which prizes were offered for the best exhibition Apples, kitchen and dessert varieties, six fruits of each variety. There were eight competitors, and after a careful consideration of the respective merits of the exhibits, which approached very closely in value, the premier honours were accorded to Messrs. Bunyard & Co., Maidstone, Kent, who had about ninety dishes of admirable fruits, many of great size and beautifully coloured. The most notable were Worcester Pearmain, Grenadier, Calville Rouge Précoce, Yorkshire Greening, Blenheim Pippin, Dutch Mignonne, Alfriston, New Hawthornden, Queen Caroline, Lord Derby, Peasgood's Nonesuch, Warner's King, Wealthy, Mabbott's Pearmain, Stone's Apple, Emperor Alexander, Bismarck, Washington, Gloria Mundi, Cox's Orange Pippin, Fearn's Pippin, Stirling Castle, Golden Noble, Pott's Seedling, Beauty of Kent, Cox's Pomona, Colonel Vaughan, Evargil, Mère de Ménage, Ecklinville, Calville Rouge, Royal Russet, Gipsy King, and King of the Pippins. Mr. C. G. Selater, Devon Nurseries, Heavitree Bridge, near Exeter, was second with a creditable display of fine Apples, the most conspicuous being Beauty of Hants, Mère de Ménage, Peasgood's Nonesuch, Tibbett's Pearmain, Cox's Pomona, Lady Hennifer, Annie Elizabeth, Bull's Golden Reinette, Tom Putt, Blenheim Pippin, Fair Maid of Devon, and Norfolk Beefing. The English Fruit and Rose Company (Cranston's), Limited, King's Acre, Hereford, secured the third prize; and Mr. H. Berwick, Sidmouth Nurseries, Sidmouth, Devon, was awarded the fourth prize.

For the best collection of Pears and fruits of each variety Messrs. T. Rivers & Son won first honours with seventy-five dishes, but not quite so many varieties as in the case of larger fruits, two dishes were required to hold them. Some of the best fruits were Pitmaston Duchess, Souvenir du Congrès, Doyenné du Comice, Gratioli, Marie Louise, Duchesse d'Angoulême, Beurré Alexander, Beurré Rance, Emile d'Heyst, Beurré Diel, Nouvelle Fulvie, Alexandre Lambre, Vicar of Winkfield, Gansel's Bergamot, Madame Treyve, Seedling Bergamot (Rivers), Triumphe de Jodoigne, Durondeau, Bishop's Thumb, Beurré Easter, Beurré Langelier, Catillac, Marie Benoist, Beurré Hardy, Uvedale's St. Germain, Fertility (Rivers), Princess (Rivers), and Magnate (Rivers). All were clean, fine samples, and well worthy of the position accorded them. Mr. J. Butler, gardener to A. J. Thomas, Esq., Orchard Lane Gardens, Sittingbourne, was placed second with eighty dishes, including capital fruits of Beurré Diel, Louise Bonne of Jersey, Columbia, Beurré Clairgeau, General Todleben, Duchesse d'Angoulême, Pitmaston Duchess, Durondeau, Nouveau Poiteau, Doyenné Boussoch, Maréchal de Cour, Doyenné du Comice, Prevost, Fertility, Dunmore, and Beurré Hardy. The third position was accorded to Messrs. G. Bunyard & Co., Maidstone, who had about sixty dishes of wonderfully fine examples of Grosse Calchasse, Beurré Diel, Pitmaston Duchess, General Todleben, Uvedale's St. Germain, Vicar of Winkfield, Duchesse d'Angoulême, Durondeau, Beurré Clairgeau, and Doyenné Boussoch. Messrs. J. Cheal & Sons, Crawley, were fourth.

The class for twenty-four dishes of Apples, kitchen and dessert, six fruits of each, was not a large one, as two collections only were staged, Mr. Woodward, gardener to R. Leigh, Esq., Barham Court, Maidstone, winning first honours with extremely fine specimens of unusual size, clean, and handsome. The varieties were Alfriston, The Queen, Belle Duhois, of great size; Stone's Apple, wonderfully fine; Lord Derby, large; Mère de Ménage, large and deeply coloured; Warner's King, fine; Peasgood's Nonesuch, richly coloured; Calville Malingre, Cox's Pomona, exceedingly bright in colour; Tower of Glamis, Beauty of Kent, Washington, Emperor Alexander, Blenheim Pippin, Minehall's Crab, Calville Rouge Précoce, Calville Rouge, Brabant Bellefleur, Melon Apple, American Mother, Golden Noble, Ribston Pippin, and Cox's Orange. The second place was taken by Mr. H. Waterman, gardener to H. A. Brassey, Esq., Preston Hall, Aylesford, Kent, who also had fine fruits, but not quite so many highly coloured samples; excellent were Peasgood's Nonesuch, Washington, Warner's King, Tower of Glamis, Cox's Pomona, and Queen Caroline.

A class was provided for twelve dishes of Pears, six fruits of each, in which there were eight competitors. Mr. G. Woodward winning first honours with very large and well grown fruits of Durondeau, Pitmaston Duchess, General Todleben, Duchesse d'Angoulême, Doyenné du Comice, Beurré Diel, Beurré Hardy, Maréchal de Cour, Durondeau, Broekworth Park, Fondante de Panseil, Beurré Superfin, and Brown Beurré. Mr. W. Chisholm, gardener to Sir Francis Geary, Bart., Oxon Heath Park, Tunbridge, was second, showing Pitmaston Duchess very fine; also Durondeau and Gansel's Bergamot, with Vicar of Winkfield. Mr. W. A. Cook, The Gardens, Compton Bassett, Calne, Wilts, was third, having remarkable fruits of Duchesse d'Angoulême and Catillac.

With twelve dishes of Apples there were seven competitors, Mr. Sidney H. Goodwin, Mereworth, Kent, taking the lead with Peasgood's Nonesuch, Stone's Apple, Nelson's Glory, Yorkshire Beauty, Cellini, Kentish Fillbasket, New Hawthornden, Cox's Pomona, Searlet Pearmain, Hoary Morning, Worcester Pearmain, Cox's Orange Pippin. Mr. Wm. Parker, gardener to Mrs. Evans, Moreton Court, Hereford, was a close second, his best specimens being Yorkshire Beauty, Blenheim Pippin, Warner's King, Tyler's Kernel, and Court Pendu Plat. Mr. A. Killick, Weavering, Maidstone, was third also with good fruits.

Messrs. Paul & Son, Cheshunt, exhibited a group of hardy flowers—Gladioli, Asters, Senecio pulcher, very beautiful; Rosa lucida, with reddish bronze foliage and scarlet fruits; Tritomas, Phloxes, and Pyrethrum uliginosum. Messrs. H. Cannell & Sons, Swanley, exhibited a group of Taberous Begonias in many fine varieties, also a collection of Gourds.

Messrs. J. Laing & Sons, Forest Hill, had an imposing group of Tuberosus Begonias, arranged on a table in quadrangular form, surrounded by Palms. The brilliant flowers were seen to excellent advantage, but the group was a little too formal.

Gourds were rather extensively shown, Mr. C. Osman, Sutton, being the principal exhibitor of collections. Messrs. H. Cannell, G. Sturgess, and W. Mist also showing. Messrs. G. Sheppard, Pulborough, J. Rodbourne, and G. Sturgess were the prizetakers for the heaviest Pumpkin.

The vegetables were wonderfully good, and it is seldom that so many well arranged collections of excellent produce are seen together. The Crystal Palace authorities provided two classes, one for twelve dishes of vegetables, not more than two dishes of any variety, in which the prize-winners were Messrs. J. Lambert, Onslow Hall Gardens, Shrewsbury; A. Waterman, Preston Hall Gardens, Aylesford; R. Lye, Sydmonton Court, Newbury; and W. Pope, Highchere Castle, Newbury. The other was for six dishes of vegetables (cottage only), the prizes going to Messrs. H. Gibbs, Church Green, Ightham, Sevenoaks; N. Goring, Three Bridges, Worth, Sussex; and W. Thayer, Crawley, Sussex.

Special prizes were also numerous for vegetables. Messrs. J. Carter and Co., Holborn, offered three prizes for the best six dishes of vegetables, to include a dish of one of Messrs. Carters' new varieties of Tomatoes (nine fruits). The winners were Messrs. C. J. Waite, Glenhurst, Esher; R. Lye, and J. Lambert. Messrs. Sutton & Sons, Reading, offered five prizes for the best collection of vegetables, six distinct varieties, including six specimens of Onion, "Sutton's Improved Reading" and six specimens of Carrot, "Sutton's New Red Intermediate." The successful competitors were Messrs. T. A. Beckett, Amersham; C. J. Waite, W. Pope, R. Lye, and A. Waterman. The first prize collection in this class was exceedingly tastefully arranged, and several photographs of it were taken during the Show. Messrs. J. Cheal and Sons, Crawley, also offered three prizes for a collection of six varieties of vegetables, the first prize being awarded to Mr. N. Goring, Three Bridges, Worth, Sussex. The Standard Manufacturing Company also offered several prizes, which were awarded to Mr. E. Sturgess, gardener to R. B. Fearon, Esq., Banstead, and Messrs. G. Bunyard & Co., Maidstone. A first-class certificate was awarded to Messrs. Hawkins and Bennett for the early flowering Chrysanthemum Mrs. Hawkins, a golden sport from G. Wermig, which had been previously certificated by the Royal Horticultural Society and National Chrysanthemum Society.

Miscellaneous.—Messrs. J. Veitch & Sons, Chelsea, showed ninety dishes of Pears and nearly 200 dishes of Apples, all clean well grown specimens. Messrs. T. Rivers & Son, Sawbridgeworth, exhibited a number of fruit trees in pots, chiefly Apples and Pears, with one Cherry named Guigne de Winkler, very late, and of fair quality. One variety of Apple named Bijou was extremely beautiful, a small specimen 4 or 5 feet high, and having about forty fruits of a rich red colour. Mr. J. Butler, Orchard Lane Gardens, Sittingbourne, showed some fine Pears. Messrs. Peed & Son had a collection of Apples and Pears. Messrs. J. Cheal & Sons, Crawley, had a collection of Apples and Pears, amongst the former capital fruits of the Forge Apple, King of the Pippins, the Nanny Apple, and Yorkshire Beauty.

NOTTS HORTICULTURAL AND BOTANICAL SOCIETY.

The usual monthly meeting of the Notts Horticultural and Botanical Society was held at the Nottingham Arboretum Rooms on Wednesday last, October 9th. The display of fruit and Potatoes was the best the members of the Society have yet made, and the attendance was very large. Amongst the principal exhibitors were Mr. H. Fletcher of Annesley, Notts, who had over forty varieties of Potatoes in splendid condition, several of which are seedlings of great promise, and are now the subject of experiment by the Royal Horticultural Society. A local variety called Basford Beauty was remarkably fine, as also were Lord Tennyson and Beauty of Hebron. The Society awarded their first class certificate to this collection. Mr. H. Merryweather of Southwell staged excellent specimens of his well known Apple Bramley's Seedling, large, solid, splendidly coloured fruits averaging from 10 to 12 ozs. each. So good were they in every respect that the Society's certificate of merit was awarded for them. This Apple is being largely grown in this neighbourhood, and the reports of its cropping and keeping qualities are of a favourable character. Dr. Powell of the Coppice Asylum, Nottingham, sent through his gardener, Mr. Brown, a large and varied collection of vegetables and fruit, numbering about fifty varieties. His Potatoes, Brussels Sprouts (Northaw Giant), Peas, Celery, Carrots, French Beans, Cauliflowers, and Turnips were wonderfully well grown and much commented upon by the members. So excellent was this collection that the Society awarded its certificate, which it well deserved.

The President of the Society, W. H. Farmer, Esq. (gardener, Mr. Attenborough), sent fifty varieties of Apples and Pears, including most of the popular varieties; but by far the finest examples of Apples and Pears came from Clifton Hall Gardens (gardener, Mr. Anderson), Pitmaston Duchess Pears turning the scale at 1 lb. 5 ozs. each, a splendid sample; Beurré Diel and Marie Louise were likewise excellent in quality. Amongst his Apples was a seedling variety of excellent

promise, possessing an agreeable flavour, and said to be an excellent keeper; in appearance it bears some resemblance to Cellini, but in flavour it far surpasses that variety; it is alike excellent for culinary table purposes. Blenheim Pippin, Worcester Pearmain, and Spencer's Favourite were amongst his other best dishes.

J. Wesley Lewis, Esq., Hardwick House, Nottingham, sent thirty varieties of Apples and Pears, Warner's King, Maltster, and Cellini Pippin being amongst his best Apples. C. J. Cox, Esq., Basford, Notts, also staged a good collection of Apples and Pears; also some nice pans of Pleione, intermixed with small Ferns. Mr. Baker of Basford had a variety of cut Cineraria flowers, and a fine sample of Marie Louise Pear; whilst Mr. J. B. Hallam, an artisan grower, set up a quantity of Chrysanthemum blooms, which showed every indication of careful culture. James Booth, Esq. (gardener, Mr. Ralph), exhibited table plants and a collection of fruit. After a careful inspection of the many meritorious exhibits a discussion upon the fruit crops was introduced by Mr. N. H. Pownall, and was taken part in by members. Many of the exhibits remained on view the following day.—J. H. WALKER.

FRUIT FORCING.

PEACHES AND NECTARINES.—*Earliest Forced House.*—The trees are at rest, and promise well. The buds are not too large—a good sign, and through the lights being removed some time, the borders have been thoroughly moistened; therefore there is no fear of the buds falling. The trees should be pruned, dressed with an insecticide, and the whole house cleansed. The trees might be tied to the trellis, everything forwarded so that a start can be made without delay when the proper time arrives. The lights must remain off until the time of closing the house; or if the lights are fixed, which is a great mistake, the inside border must not lack moisture, and air must be admitted to the fullest possible extent.

Second Early House.—The trees are casting their foliage, and the roof lights should be removed. The exposure of the trees has an invigorating tendency; it insures perfect rest, and the rains do much to free them from insects, besides thoroughly watering the inside borders down to the drainage. When the foliage is all down give the necessary pruning, dressing with an insecticide, and cleansing the house may be proceeded with, removing the surface soil down to the roots, and supplying fresh material, but not covering the roots deeper than 3 or 4 inches. In the case of fixed roof lights watering may be necessary; under no circumstances must the trees be allowed to become dry at the roots.

Midseason Houses.—The trees in these are in the proper condition for lifting. It must be done with dispatch, all the materials being in readiness. Provide efficient drainage, shortening any strong roots, and bringing any that are deep nearer the surface, employing the compost moderately firm. Good loam rather strong, with an admixture of a sixth of old mortar rubbish, and a sprinkling of crushed bones and a similar proportion of charcoal, will grow Peaches and Nectarines perfectly. If the soil be light, add a fourth of clay marl, and if very strong, a similar quantity of road scrapings. Avoid manure, except at the surface. Give a good watering, and the trees will soon be established in the fresh compost. If trees are judiciously treated at the roots whilst they have foliage, the fruit seldom fails to set and stone satisfactorily. Borders that have the surface a soapy mass and it is not possible to remove it, may have a good dressing of quicklime quite an inch thick, mixing it with the surface soil as deeply as the roots allow without much disturbance.

Latest Houses.—Good late Peaches are very valuable. The best with us is Sea Eagle, a large showy fruit, well flavoured, with a juicy melting flesh. It is one of the best late sorts, devoid of the stringiness and mealiness too prevalent in some late Peaches. As the wood is not too ripe the house is almost closed by day so as to insure a good heat, there being, of course, enough ventilation to insure a circulation. Any trees that have too gross wood should have a trench taken out as deep as the roots, and about one-third the distance from the stem the trees cover of trellis, and left open for a fortnight, then filled in again firmly.

CUCUMBERS.—Place out the latest plants which are to afford a supply of fruit about the new year on ridges or hillocks, training with a single stem to the trellis, up which they may be allowed to advance about two-thirds, when the lead may be pinched. Those not having the convenience of a Cucumber house may secure fair supplies of winter fruit by growing the plants in pots or boxes, training the growths near the glass over the pathways in stoves, fruiting Pine houses, or other heated structures. Plants in bearing should not be overcropped or the fruit allowed to remain longer than it is fit to cut, removing all deformed fruit in a young state. Maintain a night temperature of 70°, 5° less in the morning, 75° by day, up to 85° with sun heat, admitting a little air at the top of the house at every favourable opportunity. The evaporation troughs should be charged with liquid manure, and the floors damped about 8 A.M. and 4 P.M., dispensing with the syringe.

Reduce the supply of water at the roots, but not so much as to cause flagging. A few horse droppings sprinkled on the beds occasionally will benefit the plants through the waterings and the ammonia given off. Keep the foliage thin and the glass clean to secure thorough solidified growth.

MELONS.—In houses the supply of fairly well flavoured fruit will be kept up for some time longer, the latest fruits being only swelling. Sufficient moisture will be secured to this crop by damping in the morning and again early in the afternoon, affording water to the roots moderately; a supply once a week will be sufficient. All superfluous laterals must be cut out so as to afford the principal foliage the benefit of the autumn sun. Plants with fruits approaching ripeness must be kept dry and a brisk heat maintained with rather free ventilation, the temperature being kept at 65° at night, 70° to 75° by day, rising to 85° or 90° from sun heat, affording a little air at the upper part of the roof whenever the weather is favourable.

One of the best Melons for late work is Scarlet Premier, the fruit keeping a considerable time after cutting. Any fruits approaching ripeness should be cut with a good portion of stem, and placed in a house with a gentle warmth, where they will ripen and be welcome additions to the dessert.

KITCHEN GARDEN.

THE POTATO DISEASE.—At one time in July and August we thought the present was going to be an exceptionally good Potato year, but it has proved otherwise, as the disease made rapid progress in September, and many of the late crops are badly affected. Some of those which were stored in apparently good condition have since become diseased. All such should be examined and every decaying tuber removed. Late crops which it is intended to store in clamps under straw and soil should be kept in a cool airy shed for a week or two before being put away, as if once under the soil they cannot be readily examined; and to enclose diseased tubers, however little they may be affected at the time, may soon end in the destruction of the bulk of the crop.

PROTECTING MATERIALS.—Winter is fast approaching, and protecting materials should be in readiness. Old mats, straw, and bracken are useful for sheltering young Cauliflower plants, Lettuce, Endive, Celery, &c. The bracken is especially useful. It should be cut before it is too much withered, and it should be stored before it has become very dry to prevent it crumbling away prematurely. Where Carrots, Beet, &c., cannot be lifted and stored, a covering of bracken put over their tops in frosty weather will give a great amount of protection. Potatoes that are difficult to be all accommodated in the dark may be kept from becoming green by placing a layer of bracken over them. It does not lie so close as straw or hay, and the air can circulate through it as long as it is kept dry.

TOMATOES.—Open air fruits have ripened well during the last six weeks or more. The cold nights, however, are now impeding their swelling, and unless they can be protected with glass lights it will be best to cut the fruit off and hang it in a warm room to mature. If touched by frost before being cut they will decay. Plants under glass that are still carrying some fruit and a great deal of foliage should be relieved of much of the latter, as the fruit will both swell and colour better. We have some plants on a shelf in a lean-to Pine house that are bearing more fruit than leaves, and the fine clusters attract the attention of all who see them. We make sure of retaining a good variety by cutting in the autumn, and keeping these on in small pots as stock plants for spring. Inserted in sandy soil and kept in a close atmosphere the cuttings root in a fortnight. In saving seed of Tomatoes only the best fruits should be chosen.

MULCHING ASPARAGUS ROOTS.—Where Asparagus roots have failed to make satisfactory progress during the summer they may be improved to a considerable extent by placing some half-decayed manure round the stems at once. This will be found particularly beneficial in light soils, and Asparagus should never be planted in heavy material. The roots are very thick and fleshy, and absorb food in winter. Roots intended for early forcing will be much benefited by this treatment.

BRUSSELS SPROUTS.—These have grown and buttoned very freely this season. They are more forward than usual, and as the sprouts are ready some may be tempted to use them, while other vegetables are spoiling. It would be much better to reserve the sprouts until nearer midwinter, as, although they are ready for use now, they will not deteriorate if allowed to remain on the stems for three or four months at least.

EARLY SAVOYS.—We have cautioned readers against having these too early. We recently saw about quarter of an acre raised in April now all burst and useless. Our own, that were sown and planted much later, are in prime condition.

NOTES ON BEES.

FEEDING BEES.

THERE are two extremes in this—namely, slow and rapid feeding. The former worries out the bees, wastes sugar, and serves no good purpose whatever. The latter is apt to engender foul

brood, and sometimes the combs collapse through the excessive heat raised by the bees. From 2 to 4 lbs. of sugar daily is quite sufficient for any hive, and by this method safety is ensured. Of course where under feeders are used, feeding should only be done between sunset and sunrise.

FOUL BROOD.

In three different apiaries this season foul brood has appeared, and in all the three, on inquiry being made, old honey had been used as food, in combination with sugar during the spring and early summer. Sugar alone is the best and safest food to give bees at all times.

JOINING BEE^s.

This is a practice still followed by many bee-keepers, but one which I have for many years abandoned at this season, seldom seeing or experiencing any benefit from it, my nuclei often proving the most profitable stocks the following summer. There are various ways of uniting two colonies. Some make a very bungling job of it, often getting more than half of the bees killed, and not unfrequently both queens. A safe way of uniting two colonies is to drive both lots and cage the queen to be kept on the combs, and while the bees are gorged with sugar or honey shake both together, or set that having the queen over the others and let them gradually creep together. A little essence of peppermint in the syrup the bees are sprinkled with is an advantage, or if a few hours previous to joining a bit of camphor is placed on the floor of each hive, and both lots of bees are fed, there will be no fighting, especially if a frame of bees and comb from each hive is placed alternately in the permanent hive. Bees so mixed seldom fight. Where surplus hives are at command, immediately before the great honey flow is the best and proper time to unite bees, not at any time after.

AGE OF BEES.

At the present time I observe bees in my apiary that were hatched not later than in May. I doubt not but many of the bees living now will be alive in May, 1890.

MODES OF PREPARING BEES FOR HEATHER.

To those who are within reach of Heather it is absolutely necessary if profit is expected to have strong stocks. The stocks we have been most successful with have always been unswarmed ones, having a young queen introduced about a month previous to the Heather being ready; but as the swarming system requires less capital to work during bad seasons or winter it is not to be despised, because when they are so managed to swarm early it gives three stocks instead of one during the ingathering of honey, and by the time the Heather is in order all are equal to any non-swarmers, and if the work of uniting takes place at the proper time are far superior. The surest thing to prevent swarming at this season after a young queen is to deprive the bees at the first opportunity of some of their honey—supers if possible.

Some years since I described a system of driving the bees into empty hives before taking them to the moors, and acting as the year was favourable or unfavourable with bees and deserted hives, the chief aim being to renew the combs annually, and at the same time to secure the largest amount of pure white Heather comb, so much desired by lovers of honey—a quality of honeycomb many know little or nothing about, unobtainable from hives where the bees have access to the supers right over the brood nest.

Others, again, after the bees have been driven from their combs and stores about three weeks after the issue of the first swarm, break up all the comb, giving the bees an empty hive, attention being paid to prevent death only should unfavourable weather occur. I have known hives so dealt with in a good season rise in weight 70 lbs. during the month of August. Others, again, take all their stocks, first and second swarms and old stock, to the Heather, and at the end preserve the second swarm with the bees of the old stock and first swarm added. This system has sometimes proved remunerative, but taking one year with another I am inclined to think that uniting the first swarm bees to the queen of the old

stock before the Heather season more honey would have been gathered; but it brings us back to the old question, How can the bees be best disposed of without the aid of brimstone? A series of years, such as 1888-89 has been, leaves no room for destroying bees, but the reverse; but should seasons turn out as we wish I am inclined to think that many bees will have to be subjected to the brimstone pit we are all so anxious to avoid. The best way to accomplish it is on the non-swarmling and uniting in July system.

HOME APIARY.

Nearly all my hives are prepared for the winter, well protected from wet, the entrances reduced to not more than three-quarters of an inch wide. This keeps away all draught, and the ventilating floor prevents evil consequences. The fine weather we are now enjoying is giving the bees ample opportunities for exercise, preparing and fitting them to withstand an Arctic winter should it appear. Everywhere hives are in better condition for wintering than they were in the autumn of 1888, and this state of matters is more promising for a good harvest in 1890 than we could expect in 1889.—A LANARKSHIRE BEE-KEEPER.

TRADE CATALOGUES RECEIVED.

Wm. Paul & Son, Waltham Cross.—*Catalogue of Roses, 1889-1890.*
Charles Turner, Slough.—*Catalogue of Roses, Fruit Trees, and Nursery Stock.*
S. P. Dixon & Sons, Hull.—*Catalogue of Roses.*
Jefferies & Son, Cirencester.—*Catalogues of Trees and Roses.*

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Large Sales (W. F.).—What you send for publication is purely an advertisement, and a very striking one. The publisher will send you the terms for insertion if you desire to have them.

Exhibiting Orchard House Fruit (W. J. and S. T.).—You will find the purport of your letters embodied in the first article in the present issue of the Journal, and we think it is not unlikely a change will be made of the nature suggested.

Malva Seed (C. Guernsey).—We do not remember that anything of the kind you mention has appeared in our columns, though we may have overlooked it. If you can quote the page on which the difficulty to procure seed of the varieties you name appears, and send your full name and address, the matter shall have due consideration.

Fruit Trees for North Wall (A. W. S.).—The American Bramble, if it grew well, would cover a wall twice the height of yours, and we are not certain that the fruit would ripen well without sun in your district. Red Currants or Morello Cherries would be more likely to give satisfaction, both bearing and ripening well on north aspects in South Yorkshire.

Sulphur to Vine Roots (W. Palmer).—We are obliged by your note. We discovered the misprint too late for rectification. The word "roots" in the sixth line from the bottom of the article on p. 306-7 last week should have been "pipes." Most gardeners, however, know that sulphur is not applied to the roots of Vines, but on the pipes in wineries as an antidote to red spider on the leaves.

Vegetation on Garden Walks (F. J., Devon).—What you enclosed in a box arrived in a jelly-like mass. The weed appears to be a Conferva of some kind, and probably the walks are sodden with wet, drains being needed for carrying off superfluous water. However, we have never known any vegetation that did not succumb to the "weed killers" that are advertised. They will, we suspect, kill everything that grows if applied strong enough, and they are not expensive.

Liquid Manure (A. Youngster).—We are sorry to say your short communication on this subject will not, as you say, "pass muster." You by no means make clear what you intend to convey, the sentences being so involved. Only one is plain—namely, that in which you say "unhealthy plants have been improved by liquid manure," and cite as examples some pots of Lachenalias. This is all we can extract from what we are compelled to describe as your carelessly written article.

Transplanting Roses (Engineer).—We have no doubt your Roses can be successfully removed, and the sooner the work is done the better after most of the leaves can be shaken or rubbed off the stems; indeed, we should not hesitate to cut them off and transplant at once; if left on after removal they conduct the moisture from the stems by evaporation. Do not permit the roots to become dry in transit, trim off any broken ends, place light gritty soil in contact with them, then fill in with the ordinary soil, pressing it down, and cover the surface with manure. Any strong growth may be shortened to a foot or so in length, pruning closely towards the end of March or early in April according to the weather. They ought to grow well in such soil as you describe.

Planting Rhododendrons (E. W.).—There is no better time than the autumn for planting these shrubs, but they will answer when planted under favourable conditions of soil and weather any time during the next five months. They are the most accommodating of shrubs to remove, and if due care be exercised in the work not one out of five hundred of healthy, well rooted examples will fail to grow. A mixture of turfy loam that contains little or no lime, leaf soil, and turfy peat in equal parts, will answer your purpose, pressing it down firmly. In some districts these shrubs grow well in loam without any admixture, and much better than in some kinds of peat. They do not answer where the soil is shallow on a hard, dry subsoil; nor do they succeed in any soil where the ground is deeply dug amongst them annually. It should be merely scratched over, and top-dressings of decayed vegetable matter never fail to have a beneficial effect.

Culture of Dipladenia amabilis (T. H.).—The plant will not require cutting down now. Keep it growing slowly until spring, when it can be placed in a brisk stove temperature, syringing frequently, and maintaining a humid atmosphere, but be careful not to give too much water to the roots, as Dipladenias are easily damaged in this respect. Just keep the soil moist, but never waterlogged or stagnant. Next autumn the growths may be cut back to within 5 or 6 feet of the pot and treated similarly in other respects. The shoots must be trained to a trellis for exhibition, but when growing they can be trained to strings taken from the pot to the roof of the house. Give the plant a light position, and do not allow much root space. A 24-size pot will be sufficient for a good specimen, and you will probably only need a smaller one at present.

Culture of Antholyza (Idem).—The Antholyzas generally require a cool house, but in some positions they will succeed out of doors. They are best grown in pots of light sandy soil. Give plenty of water if growth is now advancing, but do not have the plants in too warm a place or they will become weak. An ordinary greenhouse suits them well enough. You can use the lime for the plants named, but it would not be safe for Heaths and hardwooded plants generally.

Autumn Pears (Mum).—We presume from your remark that you do not wish for late varieties that remain long on the trees, but sorts that can be gathered when nearly ripe and soon afterwards ready for use. The following half-dozen combine good size with quality, and afford a supply of fruit over three or four months:—Williams' Bon Chrétien, Beurré Superfin, Marie Louise, Louise Bonne of Jersey, Pitmaston Duchess, and Doyenné du Comice. The last but one is not a Pear of the first quality, but is included because of its large size and handsome appearance combined with fair quality. If you prefer a smaller Pear of richer flavour plant Fondante d'Automne. We should plant single cordons about 20 inches apart, having as many of a sort as the length of the wall permits. Train them upright or nearly so the first year, not taking off the tops except any that may terminate with a blossom bud, but cut back any side shoots to within an inch of their base. When the trees are growing freely and nearly reach the top of the wall, they can be depressed and secured at an angle of 60° for the season, then brought down to 45°, gaining a length of 3 feet of stem over keeping them upright. The trees are cheap, easy to manage, and cover in the quickest time.

Chrysanthemums Damping (F. J.).—It is very difficult to point out the cause of your blooms damping without seeing them and knowing exactly how they have been treated in every respect. If the plants are active at their roots, we are inclined to think they may have been left outside too long, and have been slightly checked. Damping is also due to a superabundance of moisture in the atmosphere and defective ventilation. During changeable weather the utmost care is necessary to maintain a uniform condition of moisture in the atmosphere. When the sun bursts out brightly, and ample ventilation is not quickly provided, the moisture of the atmosphere is condensed on the florets, and quickly ends in their destruction. The varieties you name are very liable to damp, especially in a house where a little fire heat may be used and the atmosphere close and rather moist. They always open best when housed before the flower buds are too far advanced, and where they can have liberal ventilation. Any attempt at hurrying them frequently ends in damping. With the best of men scores of fine blooms are often lost after a fog. It is possible that a few early buds on some of your plants may have been taken, and this will account for other

plants running up so much taller on the same plant. Sometimes insects destroy the bud, and the shoot has to be allowed to extend again to form another bud. Sometimes they miss showing a bud that would develop into a good bloom. It is not uncommon to see buds on plants such as you describe in different stages of growth and height.

Gladiolus and Daffodils (*T. W.*).—Boxes 5 inches deep will do very well for Gladiolus The Bride, but we should prefer to place them in 5 or 7-inch pots. Arrange them in the greenhouse or any other cool structure where they can be covered with cocoa-nut fibre refuse or ashes until abundance of roots are formed and growth has commenced. When in this stage remove them to a temperature of 50° to 55°, where they can be kept near to the glass and a little ventilation can be given daily. Directly the flower spikes are visible a temperature of 60° may be provided. They will bear a higher temperature from the time the flowers show signs of rapid development, but they do not possess the substance they have when brought forward in a lower temperature. By this time the Daffodils and Narcissus should have rooted abundantly and be ready for removing from the material in which they have been plunged. It is important to pot these bulbs early when the flowers are needed in good time. Plants that are ready for removal from the plunging material now, and are gradually exposed to light in a frame and are allowed to remain for a fortnight after they are green in a temperature of 50°, increasing it gradually, will soon commence rapid growth. The temperature may be gradually increased 5°, and to 60° in their last stages of growth. Daffodils should not be hurried until the flower is visible. These bulbs do not bear hard forcing well, and if they are to unfold their flowers and give satisfaction, they should have a moderately lengthened season of growth. Starting them early, and bringing them on gently until the last two or three weeks, is the secret of success. If you grow them well the first year they force better and can be had earlier the second.

Black Hamburgh Grapes not Colouring (*W. B.*).—When the crop is good and advances satisfactorily to the ripening stage, then refuses to colour, it is certain something is wrong. Either the roots fail to transmit the necessary amount and proper description of nutriment, or the elaborating functions of the leaves are defective. The rooting medium contains only so much plant food—it is liberated and assimilated as such by atmospheric action, and in proportion thereto rests its value. Roots in the subsoil transmit poor watery sap, the leaves in the early stages having less elaborating power are formed large and thin in texture, and the wood is correspondingly long-jointed. Want of colour and shanking are due to poverty—insufficient and improper food, either by injudicious manipulations or non-essential supplies. In your case, as the border is small, and more roots probably outside than in it, we should not lift the Vines, but pursue the course you have entered on as most likely to lead to success—viz., encouraging fresh growth, increasing the power of elaboration, thereby securing more assimilated matter or stored food. Let the Vines start naturally, then afford a gentle warmth in the pipes, so as to admit under favourable external conditions of a free circulation of air, and train the growths thinly, so that each of the principal leaves will when fully developed have full exposure to light, and not allow more lateral growth than there is space for without interfering with the main foliage. Encourage extension, train up fresh canes wherever there is room—in brief, get more foliage, even if older canes or rods have to be cut away, yet never allow crowding. With this you will secure stronger textured leaves, which will not evaporate nearly so much under powerful sun, and will not be so liable to fluctuation in its assimilating functions as the thin and flabby, therefore more calculated to bear unprejudiced the vicissitudes of climatic and cultural strain. Crop lightly, and restrain superfluous growth early and persistently. Remove some of the soil and add fresh, so as to bring the roots nearer the surface, and mulch it with some enriching material now, leaving enough to cover the surface lightly. Give a thorough soaking with liquid manure in a tepid state a little before the Grapes colour, and cast the bedding plants away.

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (*W. P.*).—1, Greenup's Pippin; 2, Golden Winter Pearmain; 3, Rymer. (*H. F.*).—2, Minchall Crab; 3, Blenheim Pippin; 4, Fearn's Pippin; 5, Lemon Pippin; 6, Norfolk Beefing. (*Saxon*).—2, Dumelow's Seedling, highly coloured; 3, Cellini; 4, Golden Winter Pearmain. (*J. Witherspoon*).—1, Trumpington; 2, Melrose; 3, Lemon Pippin. (*James Harris*).—1, Nouveau Poiteau; 2, Catillac; 3, Winter Nelis; 4, Doyenné Boussoch. (*H. Wright*).—Lane's Prince Albert. (*J. G.*).—The small Pear is Brougham; the large one is one of Van Mons' seedlings, named Amande Double. (*J. Cooper*).—1 and 2, Golden Winter Pearmain; 3, Calville Rouge d'Automne; 4, Alfriston; 5, Petworth Nonpareil. (*W. Crowder & Sons*).—Bramley's Seedling.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*W. B.*).—1, *Osmunda cinnamomea*; 2, *Adiantum cultratum*; 3, *Adiantum concinnum latum*; 4, *Microlepia hirta-cristata*; 5, *Adiantum his-*

pidulum; 6, *Adiantum macrophyllum*. (*G. W.*).—1, *Calamintha clinopodium*; 2, *Helianthus decapetalus*; 3, *Aster Amellus*. (*H. P.*).—1, Too withered; 2, *Sedum Sieboldi variegata*; 3, *Ophiopogon jaburan variegatum*; 4, *Begonia semperflorens* variety. (*Cambrian*).—1, Insufficient; 2, *Sedum*, insufficient for identification; 4, *Asplenium bulbiferum*; 5, *Sedum album*; 6, *Phytolacca decandra*; No. 3 not included. (*R. H.*).—*Polypodium pectinatum*.

LANDLORDS' FARMING.

SEED SELECTION.

THE term of economic liberality which we explained in our last article applies to nothing with more force than to expenditure upon farm seed of all kinds. Repeatedly have we shown the folly of using tail corn for seed, and in our own practice we have striven hard to use the best seed to be had for our purpose. Tenant

farmers are wont to discuss landlords' farming in a half pitying, half humorous manner. "Let him try his hand and see if he can make a rent," say they. Well, landlords have tried their hand per force of circumstances, and in many an instance the result has been a heavy loss, but in others there has been success, which is all the more important from the extraordinary difficulties which attend the work of reclaiming most of the land falling upon the landlords' hands. Our readers know the process full well, and we need not repeat an oft-told tale of draining, tillage, and manuring. But we may remind them that when all this outlay has been incurred good seed must be had to render our work complete.

Very tempting are the samples of seed corn to be seen upon the stands of seed merchants at agricultural shows, but they cannot be taken alone as a guide to the purchaser, for they are often hand-picked grain by grain. If he is tempted to give an order he should insist upon taking a sample away with him, and see subsequently that the bulk is equal to sample. Our own plan is to give a trial to all new introductions of fair promise, but to do it with moderation, and so prove in a small way if novelties are really worthy of extensive cultivation. For example we may take Wheat, and we shall find that it is not always the large showy ears that turn out most profitable. We have had better results from White Chaff, Red, and other select varieties of Square-headed Wheat than from Giant Whites and other long-eared sorts. There is, however, no fixed rule, and much must always depend upon individual observation and judgment. The latest introduction among Giant White Wheat is Salvator or Mountain Ash, which has now been on trial for two years, and has proved so satisfactory that it will be grown extensively in East Anglia next season. One cautious farmer who watched the growth of a small field of it this year is so convinced of its excellence that he has ordered enough seed for fifty acres. It should not be forgotten that this new Wheat is really a white variety of Rivett Wheat, and that it will answer well on heavy land. For mixed soil the White Champion is the best white Wheat we have had, but it does not answer so well on heavy land, and will be replaced there by Salvator. Champion is, in our opinion, quite as hardy as Hunter's; it stands up well, and we had hardly any of it beaten down this year. We do not recommend its culture to the exclusion of all other sorts, but with good soil anybody may venture upon sowing it extensively.

The mention of seed selection is a reminder that every home farm should have its trial ground to test both seed and manure. We know nothing more interesting and instructive than this, and it need not be extensive to prove thoroughly useful. Plots only 3 or 4 yards square will suffice, and they should be divided by narrow paths, and be arranged on each side of a tolerably wide central path. The plots are then grouped so that the different sorts of Wheat, Barley, Oats, &c., are sufficiently near together for observation and comparison. Roots, forage (Grasses and Clovers included) should also have sections devoted to them. We have derived so much pleasure and instruction from our own trial ground, that we wonder at not meeting with others more frequently. Certainly a landlord would be doing good service both to himself and his tenants to establish a trial ground at the home farm. It would tend to resolve doubts upon many a question both of crops and cultivation, for depend upon it the results of such trials are of much practical importance, and are really applicable to general practice. This is the best time of year to begin a trial ground, Wheat, winter Beans, Peas, Oats, and Barley being sown at once. Manure trials might also begin at once upon the winter corn plots.

Meanwhile we cannot go far wrong if we use pure seed of really well known sorts, till we obtain such particular knowledge from our own trials as will enable us to put a certain amount of individuality into our cropping. If purchased seed corn contains many small grains as it is so apt to do, it always answers to pass it through a good corn screen once or twice, so as to get rid of all

inferior grain. This must be insisted upon, and we must not allow the plea that time is precious and the seed is good enough, for no inferior seed is worth sowing, and the time is certainly not lost in getting rid of it.

WORK ON THE HOME FARM.

The earliest crops of Mangold have been placed into heaps, and we have covered with straw and soil for winter. The leaves will be ploughed in at once, as we consider much more good is thus done to the land than is possible by turning the sheep in to consume the leaves. Unless sheep are folded upon land they do only a little good, and we have such an abundance of grass that there is no need to feed the Mangold tops. The heavy crop of acorns will do the sheep much good, as they are very fond of them, and always show improvement in condition when they have them, care being taken not to leave the sheep long enough under the trees to consume all they can at first. This precaution applies to every change of diet. Many a valuable sheep has been lost from eating greedily of Barley ears on the stubbles, of soft succulent Clover, and other green food. During the present autumn an experienced farmer lost half a dozen valuable ewes in one day from hoove or distension of the stomach with gas, generated by overfeeding with early Turnips having very long leaves. It should be clearly understood that hoove is not a disease, and is to be avoided by the exercise of ordinary precaution in giving sheep only a certain quantity of such food.

A mistaken but very general impression leads to the supposition that foot rot is induced by keeping the flock upon pasture at this season of the year. If that were so what would the great flock masters of the south do? Rely upon it much more harm is done to the sheep by persistent folding on arable land in wet weather. Give the flock a change as often as possible, even if it is only a gentle turn of two or three miles over a good hard road. Let there be a change of diet occasionally, and plenty of mixed food. Let the sheep always have access to rock salt. See that the shepherd has a sharp handy knife—not a huge weapon approaching the size of a dagger—and a supply of Gell's ointment, then with care there need be no very bad cases of foot rot. The ewes must be kept in a thriving healthy condition throughout the period of pregnancy if we would have good lambs. Anything affecting the health or condition of the ewe naturally tells upon its progeny. In other words, avoid extremes, and do all that is possible to keep them healthy and in fair condition always.

OUR LETTER BOX.

Sheep Folding on Grass (J. H.).—A hurdle to a sheep is the rule in folding, and your forty lambs or hoggets (as they should now be termed) will require about that number of hurdles. A new fold is usually made every day entirely upon fresh land. It is only during heavy snowstorms or exceptionally stormy weather that the sheep require shelter. As your sheep are young keep them in the same fold forty-eight hours, and then you may rest assured that the land is thoroughly manured, and nothing more will be required to insure full strong growth next year.

Mountain White Wheat (Idem).—This new Wheat has evidently a future on mixed soil and heavy land farms, and we certainly recommend you to give it a trial. It has several advantages over ordinary Wheat; such are its exceptionally stout straw, its large grain and ears, and its abundant yield of both grain and straw. If as a White Wheat it commands, say, 4s. per quarter more than ordinary Red Rivett, and yields a third more grain per acre, it is bound to come into general cultivation. We do not advise you to try more than a single field of it at the outset, you will then be able to see by comparison if it is really superior in every respect to your other Wheats.

METEOROLOGICAL OBSERVATIONS.

REMARKS.

6h.—Dull and damp early; fair day; damp and showery after 4 P.M.
7h.—Wet early; sunshine about 9 A.M., then dull, with occasional spots of rain; gale all day.
8h.—Bright morning; shower at 1 P.M., then fine again, with a little sunshine; wet from 4.30 to 7.30 and bright night.
9h.—Bright and fine throughout, excepting a few spots of rain about 1 P.M.
10h.—Fine and generally bright.
11h.—Wet morning, with high fog; lights necessary at midday, cleared gradually, and fair evening.
12h.—Fine and generally bright.
Temperature similar to the previous week, and not far from the average; rainfall rather below it.—G. J. SYMONS.

PLANT NAMES.

— + —

THE subject of plant nomenclature is one upon which a diversity of opinions exists; each has its special advocates, is supported by particular reasons, and gains a certain number of adherents, yet the importance of the matter and the advantages that would accrue from the general acceptance of carefully considered rules render it eminently desirable some efforts should be made to provide an authoritative code. With the botanists we are not immediately concerned, but it may be said that for a considerable time some general principles have been recognised by the majority of those who are occasionally engaged in finding a suitable generic or specific name for a new plant. These primary rules have been elaborated, classified, and improved at various times, and the embodiment of the chief points in the excellent code adopted by the congress of botanists in Paris in 1867 cleared up many difficulties, and greatly facilitated botanical work.

For scientific purposes it is admitted by all that the binomial system of naming plants and the adoption of titles derived from the Latin or Greek are indispensable. Classical names, too, have the great advantage of coming within the knowledge of Europeans generally who may not have mastered the language of the person who bestows the title or who writes the description. This is the great point against those who argue in favour of the extended adoption of popular or vernacular names—*i.e.*, they are comparatively useless and meaningless in another country. It is true that classical names present an impediment to the popularity of a plant, and though "a Rose by any other name might swell as sweet," yet if we had been compelled to call it a *Sigmatostalix* or some such elaborate cognomen it would have been a serious bar to its advancement. When a botanical name is propounded to a lady or an uninitiated amateur the first question is invariably, "What is its English name?" The English language, too, is now spoken and written by so many millions of persons in Great Britain, and in the Greater Britain across the ocean, that a popular name does possess somewhat more value than it would in Italian and Spanish, or even in French and German. It therefore appears that two forms of nomenclature are required—first for scientific purposes, in which botanists are concerned in determining genera and species; and secondly, for popular use, in which every nation will employ names in accordance with its vernacular, and easy of pronunciation by the native tongue.

The preceding remarks refer more especially to the primary grouping of plants in genera and species, but the horticulturist has to face other and more serious difficulties in his efforts to provide a suitable form of nomenclature for the numerous variations either as seedlings or sports which develop under his care. He has not only to decide whether popular or scientific names shall be employed as in the first two groups, but he has an endless series of forms to deal with of quite different and less determinate value. It also becomes to some extent necessary to discriminate between varieties that have originated under cultivation and those that have been imported from other countries. It is probable that these wildlings in some far off land have arisen in precisely the same way as those in our gardens. They may be, and most likely are, merely seedlings from one or two parents, or possibly the result of crosses; still, they are Nature's offspring, and it is advisable, if only from an historical point of view, that the distinction

should be marked between them and those obtained under cultivation.

What has been done in this case is perhaps the best course that could be adopted, and it was that recommended by M. Alphonse Decandolle, practically consigning these introduced varieties to the care of the botanists and subjecting them to the same rules as those by which genera and species are named. The employment of classical names at once marks them as natural variations from a particular type, and distinguishes them from forms of garden origin. All the horticulturist has thus really left to determine is the form of nomenclature he will adopt for the plants which he is so busily employed in multiplying both in varieties and numbers.

It is apparently a portion of the duties of the Orchid Nomenclature Committee appointed by the Royal Horticultural Society to provide some assistance in this matter and with so excellent an authority as Dr. M. T. Masters for Secretary, there can be no doubt that every effort will be made to perform a useful service. That some confusion exists in the naming of Orchids is manifest, and it is very desirable a system should be formulated to remove the inconsistencies which at present prevail. But had the Council gone still farther and appointed a Committee to deal with horticultural nomenclature generally it would have acted wisely and given the work a broader and more substantial basis. However, it is possible for the Orchid Committee to do good work and to institute a precedent that might be followed by the Floral Committee acting on similar lines.

The chief difficulty at present with regard to Orchids is that classical and popular names are being bestowed indiscriminately upon varieties of equal value. That is most undesirable, and presumably one of the objects of the Committee is to determine which shall have preference; but it should not be an extremely difficult matter to decide, as few Orchids can be regarded as garden varieties if we except the hybrids now becoming so numerous. It is only in the case of a limited number of species, of which *Cattleya labiata*, *Odontoglossum crispum*, and *Masdevallia coccinea* may be taken as examples, in which the variations are so numerous and the distinctions so slight that any difficulty occurs. Whether these should be dealt with classically or popularly is one of the points to be discussed, and it would be well if all interested in the matter would record their opinions.

In the case of plants like *Chrysanthemums*, *Roses*, *Dahlias*, and *Carnations*, of which so many thousands of seedlings and sports have been raised under cultivation, the popular names generally adopted are decidedly better and more appropriate than the ordinary botanical form of nomenclature would be. These have respectively originated from one or a few species, which by repeated intercrossing have given rise to a progeny that can only be classified with difficulty under particular original types. Nothing of this occurs in the Orchids; the specific groups are so much more numerous, and their characters so much more clearly defined in the majority of instances, that except with a few *Odontoglossums* little difficulty is experienced in determining their positions.

After all it is of small consequence what names are employed for plants provided there be some uniformity in the method and the names be as short, simple, and expressive as possible. Unfortunately the three points named are too frequently overlooked, and it is only requisite to glance down any list of popular plants to see how needful it is to have a general reform. By the exercise of a little thought or care it would often be easy to provide names expressing some quality in the plant or flowers, but if that cannot be effected some neat crisp title might be chosen that would be scarcely less useful. The host of personal designations are objectionable in many ways; in the opinion of many persons it is equally as undesirable to call a Rose Mr. John Smith as it is to term an Orchid Smith's variety. By all means let us have popular

names wherever possible or advisable, but let them follow some recognised rules.

One thing is most important, and that is in the revision of nomenclature the alteration of accepted names must be performed with the greatest caution, as to flood horticultural literature with unnecessary synonyms would be a positive calamity. Botanists have quite enough to answer for in this respect, and have caused each other untold troubles and difficulties in research, but there is no reason whatever why horticulturists should follow suit. Names that have been given to plants by recognised authorities, or given official value by the award of certificates by properly constituted committees, should not be touched, and any new rules must be prospective, not retrospective.—LEWIS CASTLE.

RENOVATING AND PLANTING FRUIT TREES.

I AGREE with Mr. Iggulden, page 216 of the Journal, that old and inferior varieties of fruit trees are not worth the time and trouble of either root-pruning or grafting, as the best varieties of young healthy fruit trees are very reasonable in price. Rather than spend money on trying to patch up old worn out trees, have the ground properly prepared for young trees from a reliable source. I give a list of the varieties that I have found useful. I could name many more, but if anyone will plant some of the following I do not think they will be disappointed:—For kitchen use: Bramley's Seedling, Dumelow's Seedling, Domino, Maltster, Besspool, Small's Admirable, Catshead, Ecklinville Seedling, Stirling Castle, Golden Noble, Striped Beefing, Beauty of Hants, Warner's King, New Hawthornden, Alfriston, Lane's Prince Albert, Emperor Alexander, Blenheim Pippin, and Gloria Mundi.

A few reliable sorts of quality for dessert are Cox's Orange Pippin, Ribston Pippin, Kerry Pippin, Fearn's Pippin, Margil, Golden Winter Pearmain, Irish Peach, Scarlet Nonpareil, Trumpington, Worcester Pearmain, Court Pendu Plat, Lord Burghley, and Blenheim Pippin.

What I have learnt about planting fruit trees—bush trees as well, vegetables also—is that it is a mistake to go in for too many varieties. It is better to plant twelve trees of one sort than twelve trees of different varieties. In the first place, with so many sorts there is much trouble in storing. That is not all. When there are so many patches of fruit in the fruit room there never seems to be any to go on with, so to speak; but mark the difference if you happen to have six to twelve trees of one good variety and a good crop; in that case there is often a few for market.

With reference to renovating fruit trees I can say that I have had a fair share of experience—not always successful at first, but with practice and observation failures seldom occur. The first step to take in the improvement of existing trees or planting fresh ones is to see that there is a good heap of compost available to give the roots, composed of burnt refuse, or burnt clay is not to be despised. Some gardeners are able to procure plenty of old turf; nothing can be better where available. Unfortunately the majority have to make the best of what they can secure; in that case road parings and the scrapings are very useful, and most roots will take to them. A heap of three parts road parings, one part burnt refuse, with a barrowload of old mortar added to each cartload, also a peck of soot, will make a good compost. If when planting is proceeding 1 to 1½ lb. of bone dust and half-inch bones mixed is added for each tree that will improve it. I may state that much hard work and care are needed on the part of the chief when planting and renovations are taking place. It is useless to make holes less than 6 feet across, even for bush trees; give plenty of room for the roots, and keep them near the surface. Stake as soon as planted, give a mulching of 3 or 4 inches of half-decayed manure. The last week of October and the first fortnight in November is the best time for planting fruit trees.—DISENGAGED.

[One of the many good gardeners whom we should be glad to see engaged and doing good work in gardens.]

RESTORING SHRUBS.

THE beneficial effects resulting from mulchings of manure and dressings of artificial manurial agents is well known; equally beneficial, though perhaps not so well known, are dressings of soil when applied to ground which has been exhausted by the roots of shrubs or trees. The limits need not be struck at these, as we have proved how wonderfully recuperative to fruit trees, flowers, and vegetables is the addition of a few inches of soil to the ground occupied. But shrubs are so generally starved that it may be well to limit these

remarks to them. The necessity exists for fresh food most generally in cases where trees grow among and overtop shrubs, and where leaves are carted off before decaying. It does not matter about the quality of the soil used, so long as there is a sufficient thickness spread on; 4 inches in thickness may be taken as the least quantity to prove of any permanent good. Where the shrubs are thick the whole ground may require covering, but it must be noted that a good thickness of soil spread thickly under each shrub is much better than a less thickness spread over the entire surface of the ground. The rationale of this treatment does not depend entirely on the fact that the plant is in possession of a supply of food. I do not think that an increased food supply is even the main good, but rather we must look to the vitality imparted to the whole plant through the increase of young roots, and the quality of these roots as compared with the quality and quantity of these previous to the addition of soil. I have seen wonderful results follow in the next season's growth through the liberal application of fresh material immediately over the roots of shrubs. Those seemingly dying have been brought back to health.

Another means of putting fresh vitality into shrubs in cases where the soil is strong is simply to dig a circular trench at a sufficient distance from the bole of the plant not to stop growth; the width of the trench not be less than 12 inches, but 6 inches wider is better. A sufficient opening to work with freedom and dispatch is formed at the side, and the soil simply turned over and broken up, and that to a depth of at least 15 inches. When the shrub is circled the soil thrown out is put back and the work completed. If done now or early in spring the plant will show the first season the great benefit it has received from this operation. The reason is much the same as in the case of those dressed with fresh soil in sufficient quantity—viz., the emission of numbers of strong roots in a medium more suited to a healthy growth than hard soil unbroken. Another method of throwing fresh vigour into shrubs is the drastic one of cutting them in more or less severely according to circumstances; but this, of course, has the objection of altogether altering the appearance of their surroundings when carried to extreme lengths. However, by the method of taking a few feet off particular plants at intervals of every two years it is possible to help the health of plants very much, and in any case the digging of a trench round them, or the addition of fresh soil to the surface, will not be lost labour.—B.

NOTES ON PLUMS.

Now the Plum season is practically over, it will be interesting to hear which varieties bore well, and those that were failures. I do not think the Plum crop of 1889 can be regarded as a full crop in many districts. In Herts I think we are favoured with an excellent soil, suitable for all fruits, it only requires cultivating. The climate, too, is very satisfactory. Our trees are grown on walls as standards and bushes. The standards have borne the best crops. I fear the wall trees did not have sufficient water while they were swelling their crops, for they did not attain their average size. Our season commenced with that excellent Plum Rivers' Early Prolific; the trees all carried immense crops of medium sized fruits. This tree grows well here, but Mr. Pearson tells us it will scarcely exist at Chilwell. This clearly demonstrates the fact that it is necessary to ascertain which varieties are likely to thrive in any particular district before planting. Early Orleans also carried good crops, but the trees being nearly destitute of foliage they did not attain their usual standard. Belgian Purple is represented by two healthy standards, and they cropped well; it is a capital market Plum. Angelina Burdett is a good dessert Plum, ripening in September, but it is not a very certain variety. The young trees of Jefferson failed entirely; though a grand Plum, it is very uncertain here. Kirke's was a failure. Of Oullins Golden Gage we have some very fine trees; it is a good cropper and an excellent dessert Plum, has a fine appearance, but the thin skin soon bursts in wet weather. Green Gages were nearly all small, especially those on the walls. Reine Claude de Bavay, a good late Gage, but has cracked badly. Transparent Gage.—These have been very fine; it is a handsome Plum, and deserves to be largely planted. Belle de Septembre.—A total failure. Belle de Louvain.—Very light crop, but an excellent flavoured fruit.

Diamond is my ideal black Plum, it grows very large, and the fruits are very handsome; it travels well, and above all it is a sure cropper. Mitchelson's did not bear. Poud's Seedling does well as a standard, but the skin is rather too thin for a good market Plum; the fruits were very large indeed, and a beautiful colour, but we lost the majority of our crop with the wet. Prince Engelbert.—Tree forms a very compact top, makes a good standard, very good crop. Victoria.—Always a sure cropper and a good market Plum, but with the exception of our young trees, the fruit was undersized. White

Magnum Bonum.—A good dessert Plum, rather poor crop. Autumn Compôte and Belle de Septembre were both failures. Sultan.—A medium-sized black Plum, good cropper, but the wet spoiled them. The Czar.—Good vigorous Plum, capital cropper, but fruit were small. Coe's Golden Drop.—We had an average crop both on the standards and wall trees. Cox's Emperor.—A grand Plum; we have had very heavy crops of this variety, but I believe it does not succeed well in all districts. Washington.—This is a very handsome Plum, but usually a shy bearer; we have had a capital crop. Apricot Plum.—A very old variety, resembling small Apricots, makes excellent preserve. The Damsons did not bear. Bullace are a very heavy crop.—EXCELSIOR.

EUCHARIS AND THE MITE.

SOME time ago I was brought to task by a gardener for some remarks I made regarding the Eucharis mite. In those remarks I made bold to doubt the existence of such an insect, as I had never made its acquaintance. Now to the average mind this is only commonplace logic, but he clearly exposed my ignorance by proving that there was such an enemy to my favourite flower, as he had seen it on some plants under his charge. This evidence, coming from one by whose teachings I had often profited, made me anxious to learn something of this unknown enemy while it was yet at a distance. I would much liked to have seen the infected specimens referred to had they been in existence, but as they had been consigned to the fire I had to give up the idea of gaining any information from them. Ever since I saw the grand plants at Eaton Hall, nearly fifteen years ago, I have taken more than ordinary interest in Eucharis growing, and when visiting other gardens or nurseries always took close notice of any that were to be seen. In some places they were good, in others bad, while some had even reached the superlative degree of debility. No other plant was to be seen in such a variety of stages, and about no other was there more concern apparent, or more anxious inquiries made, the flowers in all cases being much prized. Of course in a brief visit there was not time to know fully how they had degenerated to their present condition; but in no case that came under my notice could the mite be blamed as the cause, although insects frequently were seen attacking the bulbs from the effect of their debilitated state. Like all other plants, if they are not in a condition to properly assimilate the food supplied to them, the soil turns sour and insects attack the roots or bulbs as the case may be, and ultimately place them beyond the reach of recovery if suitable measures are not taken in time to restore them.

In no instance that I have yet heard of has a mite been found on a healthy bulb, but in all cases the state of the bulb has been below par. Now I never doubted that a mite or any other insect attacked a Eucharis bulb when in an unhealthy state, but I have never seen an instance which led me to believe that this mite was the cause of its unhealthy condition. From the name Eucharis mite one would naturally infer that it was an insect roaming about for plants that it might devour, instead of being the natural result of unhealthy surroundings. Several cases have come under my observation which appeared to me to prove that the mite is the effect of debility instead of being the cause, but I will only briefly notice two at present. In one instance several fine plants which always bloomed satisfactorily were, through a change in the management of the place, completely denuded of their leaves as an easy manner to get rid of the mealy bug with which they were infected. This treatment so crippled them that, although many remedies were tried for their recovery, they had ultimately to be thrown away. At the time they were turned out of the pots many of the bulbs could be seen to be insect-infested, mites and other pests tunnelling them in all directions, their existence being clearly the effect of the treatment to which the plants had been subjected and not the cause of their decay. The other case to which I refer was a similar one, though caused by a different agency. Through neglect in turning heat on to the pits in which they were the plants were cut down to the level of the pots by frost. Until then they had been excellent specimens in every respect, but for years afterwards they were a prey to parasites and an eyesore about the place. The latter were some that I had in my mind's eye when I wrote the remarks alluded to at the commencement of this article, and to show that their recovery was not a temporary one I may state that at present they give every satisfaction to their owner.

These may be considered extreme cases not likely to occur in many gardens, and are only quoted here to show the result of a check which was clearly the result of their unsatisfactory condition. Now, although the origin of the mite may not in every instance be due to checks so severe as those just noticed, yet my observations lead me to believe that in some form this is the

primary cause of the evil, and I am inclined to consider over watering one of the most fruitful causes. This opinion was greatly strengthened by the criticisms to which my former article was subjected. Take, for instance, the plants of *E. candida* which were burned after a twelvemonth of the same treatment as the fine plants of *E. grandiflora*. These plants, we are told, received copious supplies of water, frequently three times a day. Let us compare the state of the two and see whether it is to be wondered at that one should fail while the other continued satisfactory.

The large plants of *E. grandiflora* were well established, and had not been potted for years. All growers know how quickly Eucharis bulbs are increased, so that they must have been a mass of bulbs and roots capable of absorbing any quantity of water that well drained pots would allow to remain. On the other hand, the plants of *E. candida* were newly bought, and allowing them to be average samples the plants were only moderately well filled with roots. In this state they were quite unable to withstand the drenchings of water which were comparatively harmless to the larger specimens, and as a consequence fell into ill health, after which they were examined and found to be affected with the mite. If overwatering was not the cause why should it not have affected all alike?

The Eucharis requires different treatment from most other stove plants, especially as regards watering. At all times water ought to be applied with care, but particularly after they have made their growth and undergoing a period of rest. At that time they emit fresh rootlets, which in their early stages are very tender, and an overdose of water or any unnatural treatment will quickly put them wrong. When the flower spikes appear more may be given occasionally mixed with soot water, which may be continued until resting time again. If this treatment is continued for a few years the pots will be full of bulbs in various stages, so that sometimes a succession of bloom is got from one plant. When they have reached this condition water may be applied more liberally, as some of the bulbs are always active.—M. D.

RENOVATING VINES AND BORDERS.

VINES unquestionably thrive for an indefinite period in a soil suited to their requirements, and where they have a good extent of rooting area, as may be seen in many places. In many cases, however, the roots have extended far beyond the prepared border, and are practically beyond control. We have had charge of Vines the roots of which had a narrow border of only 2 feet wide, and were somewhere beneath a gravel walk 2½ yards wide, and the turf of a lawn beyond. One such Vine covered 1000 superficial feet of roof trellis, and in the 2 feet border there were no roots of consequence, or if there had been very little could be done there. The Vine had been weakened by continuous overcropping, and to seek renovation by an increase of growth was the only available means. The Vine had been pruned on the spur system for many years. We took up fresh canes—they started weakly, but gained strength as they gained length; the spurs were reduced, so that they were not nearer than 18 inches on opposite sides of the rods, and they showed before the season was over a decided improvement, as might be expected from the greater space alike of exposure to light for the foliage and the encouragement of laterals.

The pruning pursued afterwards was a modification of the spur and rod systems, and the crops were in every respect satisfactory. The roots had only 80 feet superficial space of border to support a Vine covering 1000 feet of roof surface. When, therefore, the Vines are in borders that do not admit of renovation we advise something to be done to their heads by encouraging fresh growth, even if it must displace some of the existing, affording it due space for development, the principal leaves never being crowded, in order to promote a complete assimilation of the sap and the storing of food in the wood and buds. This, with due care in culture and judicious pruning at the proper time, is, according to our experience, invariably attended with better results in the season following the procedure, and with persistence ultimately effects beneficial issues little short of those attending difficult, expensive, and not unfrequently needless border renovation. What little border there may be should be made the most of by mulching with rich material to encourage roots from the collar, and during dry time all through growth liquid manure should be given, and especially when the crop is about to colour, accompanying it with a little more freedom to the laterals, so that larger supplies of aliment may be applied and withdrawn from the impoverished subsoil, from which the main supplies of uncontrollable borders are drawn by the Vines in the perfecting stages of their growth.

Borders that are under the control of the cultivator leave no excuse for unsatisfactory Vines. With such no time should be lost as soon as the leaves have perfected the buds and wood, and whilst they are still upon the Vines in removing the soil down to

the roots and picking it from amongst them, so as to displace as much as possible. In the case of the border being unsatisfactory and the roots few and deep, it will be necessary to remove all the old soil and renew the whole border, commencing with the drainage, which should be a clear 9 inches to 1 foot thick, having a layer of fine material at the top, nothing answering better than old mortar rubbish, a 3-inch thickness over 9 inches of brickbats, &c. The drainage must have a tile drain under it to carry off the superfluous water. Two feet depth of soil is ample, and the roots should be laid out evenly in the top foot, encouraging those from the collar by laying any that proceed therefrom just beneath the surface. The whole should be made firm and the compost moderately dry. If the roots are inside and outside, one part may be done one year and the other the next without any danger of loss of crop, care being taken to preserve all the roots possible, and to keep them from the drying influences of the atmosphere whilst the work is in progress. Mulch the surface with a little short material, preferably fresh horse droppings, and cover outside borders with a good thickness of leaves or other protective material. As regards soil good turfy loam is best, but any ameliorated soil will grow good Grapes. Preference should be given to medium textured soil, that overlying clay being better than overlying sand. The most suitable is a rather strong loam overlying the limestone formation and interspersed with cretaceous matter and flints.—G. A.

PREPARING FOR BULB PLANTING.

Now that the frost has spoiled the summer arrangements in the flower garden it is time to prepare for filling the beds with bulbs for spring effect. Anyone employed in this work will find it necessary to make the best use of all fine weather until the work is completed, as the bulbs are losing valuable time whilst remaining in the shed after October has commenced. Presuming that all arrangements have been made beforehand, and sufficient bulbs procured to fill the beds allotted to them, let the latter have a dressing of soot, or lime if procurable, to assist the former to battle against any disease, or fungus, that is always ready to attack the more tender or delicate kinds. If a heavy dressing of fresh soil or well decomposed manure can be dug in, so much the better, as by using the beds each year for bulbs the soil naturally gets worn out, and a change becomes absolutely necessary. It is a good plan to have a quantity of compost prepared, say six weeks or two months beforehand, so that it is in readiness whenever required. If large numbers of beds are to be planted select some fresh loam, or what is more suitable, edgings of walks that have thoroughly decayed, say about four or five cartloads; add to this about two loads of leaf soil and an equal quantity of cow manure and coarse sand, turning it two or three times to thoroughly mix it, allowing it to remain in the heap till required. Spread this on the beds and let them be deeply dug, which is essential for successful cultivation.

This treatment applies to Hyacinths and Tulips more especially, and some strong growing Narcissi also, as they are gross feeders, but many of the Narcissi do much better without manure. *N. maximus* is one of these and often fails to flower when manure is used, although one can hardly wish for a finer variety when grown in fresh sandy soil.

When the beds are in readiness commence with the Narcissi first, if possible, as they are the most impatient to start into growth. If one variety only is used in a bed it is much the better plan to line the beds out before commencing planting, placing the bulbs evenly on the surface, not too thinly, as much of the beauty of the bloom is lost when the bulbs are too sparingly used. Hyacinths and Tulips should be treated in the same way, but beds of these will be greatly improved if a broad band of Crocuses is planted round each. The Crocuses are quite over in spring before the other bulbs are in flower, but the foliage round the edge gives a decided finish to the bed. It is hardly necessary to give the names of varieties most suitable to grow, as the list of each is a long one, and no difficulty will arise in making a good selection. To those about to replant *Liliums* I would say, Lose no time, as the bulbs have already commenced growing, and if planting is delayed they will experience a check from which it takes them some time to recover.—F. G.

ROOT-PRUNING FRUIT TREES.

THIS is an operation that now demands attention, as at this period of the year roots of most trees are active, and if the work is done early and carefully there is a chance of the trees re-establishing themselves before winter sets in, and are consequently better fitted to make good their loss of roots they are deprived of before another year. Root-pruning acts like magic sometimes in bringing barren trees into a bearing state, especially when unfruitfulness

is brought about by undue luxuriance. When trees are making very strong shoots they are found on examination to be making roots in proportion, and so long as this goes on fruit prospects are very much jeopardised. It is the small fibrous roots which command the formation of fruit spurs, and in some soils there is difficulty in maintaining a fruitful condition. In gardens where the surface is light and open, with a clayey subsoil, there is great tendency for the roots to go deep in search of moisture, especially if the aspect is at all open and windy. With soils of this description mulching is of considerable value, of no matter what kind so long as it creates and maintains moisture.

Old and exhausted trees may be invigorated by digging a trench down as deep as roots are found, fresh soil being added, with which is incorporated some mortar refuse or lime and bones. It is not advisable to add any animal manure, as this is better applied in a liquid state, but any accumulation of burnt or decayed garden refuse may be given with advantage in moderate quantities if well mixed with the soil. All roots that are severed should be cut smooth with a sharp knife, as affording assistance in encouraging a quick and perfect callus from which fibrous roots eventually issue.

With large trees root-pruning should not be completed the first year, but a half circle, as it were, dug round at one time, the remaining half left until another subsequent period. It is important that when the work is in hand the ball of roots should be undermined quite up to the trunk or main stem, as large tap roots frequently take a direct downward course, and if these are not severed the work done will not have the desired effect. The space beneath the tree requires that the soil should be well trodden in, otherwise there is danger of its shrinking, which if the tree was unable to sink with it would leave a cavity and seriously interfere with root formation. Should the soil be at all dry it must, as the filling in proceeds, be well watered, this serving to fill up crevices more effectually and quickly than when it is allowed to sink naturally. Moreover, it tends to sustain the tree under its surgical treatment. It is a very good plan when trees are operated on at the roots that the necessary pruning be done at the same time, so that the demands on the roots may be correspondingly decreased, and there is also less surface open to the wind forces.—W. S., *Frome*.

WATERING ORCHIDS.

PLANTS in the East Indian and Mexican houses must be watered with considerable care. Be careful not to keep them too wet at their roots, and on the other hand do not allow them to become so dry that their stems and foliage will shrivel. Considerable judgment is needed in this matter during the autumn and winter months. Plants that have completed their growth and have fleshy pseudo-bulbs need only sufficient water to keep their roots healthy and the leaves and stems plump. *Cypripediums*, *Vandas*, *Aerides*, *Saccolabiums*, and others suffer considerably if they are kept too dry; the material about their roots should not be destitute of moisture. When water is used it should be of the same temperature as the house or a few degrees warmer. Cold water when applied to the plants, especially when allowed to fall upon their foliage, frequently results in the latter "spotting," which destroys their appearance for several years. Use the syringe judiciously. On fine mornings no harm will follow slight syringings provided air can be admitted and the water that lodges about the plants is evaporated before it is necessary to close the ventilators. Damping the paths, stages, and amongst the pots may still be practised. It is a mistake to discontinue syringing and maintain about the plants a dry burning atmosphere. This treatment soon results in the plants being destroyed by yellow thrips.

PHAIUS GRANDIFOLIUS.

If these plants have been well looked after they will have grown strongly and have clean healthy foliage. These plants are often destroyed by overwatering early in the season, and the foliage requires trimming to render them presentable at the present time. The atmosphere in which the plants are grown should not be kept too moist or the syringe used injudiciously, or the foliage at this season will soon become spotted. Supply water carefully, but never allow the soil about their roots to approach dryness. Keep the plants in a temperature of 60° to 65°, and give them weak

stimulants every time water is needed. Soot water in a clear state and liquid manure made from cow manure, given alternately, will prove beneficial. Aphides are troublesome after the flower spikes have attained 18 inches or more high. The best means of destroying them is by slight fumigations. This plant will bear retarding after the flower spike is once visible in order to form a succession. If they are removed gradually to a temperature of 50° to 55° no harm will result. While in a lower temperature water must be given with the utmost care or the roots will perish. Few Orchids are more serviceable than this for conservatory decoration. When grouped with other decorative plants their noble spikes of bloom are most conspicuous.

CALANTHES.

These are often seriously injured in their last stages of growth by withholding water suddenly and ripening their foliage prematurely. The foliage certainly looks unsightly for a time, but this cannot be avoided, and is no reason for removing it in an unnatural manner. The supply of water must be gradually decreased until the whole of the foliage has turned yellow, when it can be removed and water withheld altogether. Weak stimulants may be given until the foliage has advanced to maturity. Those for late flowering are still growing freely, and should have a light warm position near the glass. They will do well on a shelf in a temperature of 65° now that the soil will not dry so rapidly. We have found that they do better, consequent on becoming better ripened in this position than when arranged together on a bed or stage. In the latter they shade one another and prevent full light penetrating to their pseudo-bulbs, while on a shelf they are fully exposed.

DENDROBIUM WARDIANUM.

A few flowers are always acceptable for buttonholes, bouquets, and small glasses, and therefore we prefer to have a few plants in flower to maintain a succession in preference to a large number of plants flowering at the same time. Some that flowered early last year are already starting into growth in a cool structure. The flower buds are also very prominent. A few of the most forward are being placed in an intermediate temperature, and will be allowed to come into flower. The plants should be watered with great care, giving them no more than is really necessary to keep them fresh and plump until the new growths commence forming roots, when the supply must be gradually increased. Keep plants slowly moving from the time they start into growth, but it is unwise to hurry them, or they will make their growth and have to ripen it in spring instead of summer. A few small specimens of *D. nobile* may also be started in the same manner. For this purpose young plants in from 5 to 7-inch pots are decidedly the best. With a little care and forethought the flowering season of these Dendrobies may be considerably extended.

DENDROBIUM DEVONIANUM.

For a few years after this variety is imported it appears to grow freely and do well. It then appears to dwindle and annually become weaker. Frequently the plants are seriously injured by allowing them to flower before they are established. Strong imported plants usually flower profusely, and when the flowers are removed almost directly they make their appearance they grow more strongly than when allowed to flower. The plants at first also produce growths on the stem freely, and if these are removed and growth induced from the base they all the sooner become established, and often do better than those that are allowed to become a mass of small growths. This Orchid needs the most careful treatment in ripening its pseudo-bulbs. Water must be given carefully and the plants allowed time to ripen thoroughly up to their ends. The best results follow thorough ripening in the house in which they have made their growth before removal to cooler quarters.—ORCHID GROWER.

THE BULBOPHYLLUMS.

THOUGH at least 100 species of Bulbophyllums have been described by botanists few are known to cultivators, and those rank chiefly as varieties. Some are extremely interesting structurally, and prominent amongst these is *B. barbigerum*, which has been thus described by Lindley:—"The lip is one of the most extraordinary organs known, even amongst Orchidaceous plants. It is a long, narrow, flexuose, sharp-pointed body, closely covered with a yellow felt; just within its point is a deep purple beard of exceedingly fine hairs; on the under side, at a little distance from the point of the lip, is another such beard; and besides these there is, at the end of the lip, a brush, consisting of very long purple threads, so exceedingly delicate that the slightest disturbance of the air sets them in motion, when they wave gently to and fro, like a tuft of threads cut from a spider's web. Some are of the same thickness throughout, others terminate in an oblong club, so

that when the hairs are waving in the air (and I do not know that they are ever entirely at rest) a part floats gracefully and slowly, while others are compelled by the weight of the glandular extremities to a more rapid oscillation. Nor is this all. The lip itself is articulated with the column by such a very slight joint that to breathe upon it is sufficient to produce a rocking movement so conspicuous and protracted that one is really tempted to believe

FIG. 42.—BULBOPHYLLUM UMBELLATUM.

that there must be something of an animal nature infused into this most unplant-like production."

Most of the species have small flowers, but *B. siamense* is an exception to this, as its flowers are nearly 3 inches in diameter, pale yellow striped with purplish brown. *B. Lobbi* also has large flowers, deep yellow, spotted at the back with purple. *B. reticulatum* is also attractive both for its foliage and flowers, the former beautifully veined with a dark green on a lighter ground, the flowers white striped and spotted with purple. *B. umbellatum* (fig. 42) is also worth a place with the others, the colour being

similar, but the flowers are individually smaller than those first mentioned, though they are borne in umbel-like heads. It was shown from Kew some time ago, and it has recently flowered again there. Like most of the others it is of easy culture, succeeding either in small pots or shallow pans, with good drainage, in a warm house.

LIQUID MANURE FOR FRUIT TREES.

THE question of "R. H. S." properly ought to have been addressed to Mr. Wright, to whom is due the credit of the recommendation to apply liquid manure to fruit trees, especially in winter. However, I will do the best I can to reply to it. My answer is not even a qualified no, but an emphatic yes. Apples, Pears, and other fruit trees when once established do not require mulching; cold at their roots in winter does not injure them. A mulching of leaves, inasmuch as they contain little plant food is scarcely of use except for protection from cold. A top-dressing of manure is beneficial in proportion to the plant food it contains, and a soaking with good liquid manure is valuable in the same proportion. "R. H. S." says that his soil is "cold and clammy," by which I suppose he means a strong clay loam. Such a soil would be more likely than a light porous soil to be benefited by liquid manure, as it is more capable of extracting every particle of the food elements from the liquid, leaving only the water to percolate away. Even if the soil of "R. H. S." were not well drained he need have no fear that 2 or 3 inches of fluid in addition to the ordinary rainfall would injuriously affect his fruit trees, although his soil be cold and clammy. An excess of rainfall in the winter above the average certainly does no harm except so far as it may carry away in the drainage water some of the elements of plant food; but if the excess be in the form of liquid manure the food remaining in the soil is infinitely greater than the loss by drainage, and in the event of a deficiency of rainfall, as happened in the winter 1887-8, the water in the liquid manure is as, or perhaps more, beneficial than the manure itself.—EDMUND TONKS.

FRUIT JOTTINGS.

SAWBRIDGEWORTH is a quiet Hertfordshire town of moderate extent and population, yet the name has been rendered familiar to all horticulturists throughout the length and breadth of Great Britain by its association with the historical and celebrated fruit nurseries of Messrs. T. Rivers & Son. There during two or three generations have fruit culture and improvement been made a practical and scientific study, and the results, as seen in the numerous additions to the lists of good fruits that find a place in the best gardens, and the beautiful samples staged at exhibitions, afford abundant proofs of the success achieved. Increasing the number of useful fruits and extending their season is a public service of an important character that merits recognition quite apart from the commercial advantages accruing to him who is fortunate enough to secure such novelties. Fruit is regarded as something more than a luxury now. It is a part of the food of the people, and as such its improvement or increase becomes a matter of national importance. Beyond this, however, experiments in profitable fruit culture have been undertaken at Sawbridgeworth, and many a valuable lesson has been learned there by visitors, who have turned the information gained to good account elsewhere. Specialists and enthusiasts do the best work in their respective studies or professions, and when enthusiasm is tempered by experience and guided by a close attention to the financial aspect of the work, we do not expect to find anything of a visionary or fanciful character. So it is at Sawbridgeworth, Mr. T. Francis Rivers adding to his late father's long experience his own keen observation and critical knowledge of fruits and their culture, has developed his 300 acres of land into an admirable nursery, farm and school of pomology that is in its way quite unsurpassed. A long-desired opportunity of visiting the Sawbridgeworth Nursery was recently afforded, so a bright October morning last week found us speeding from Liverpool Street down to Harlow, the nearest station for a traveller from London. Mr. T. F. Rivers was quickly found, and an inspection commenced that kept us well occupied for some hours. It would be useless to attempt to record in detail all that was seen or talked about that morning, but a few of the leading points may serve for a paragraph or two appropriately under the head of "jottings."

STOCKS.

Nine or ten acres of vigorous young trees, one, two, or three years old, were first examined—Apples, Pears, Cherries, Peaches, and Plums, in all the best varieties, the young trees as healthy, strong, and even as anyone could desire. The Apples in particular, which occupy a large proportion of the space, are most noteworthy, and for all of them two stocks only are employed. For orchard trees and standards the Crab is used, and for dwarf trees a seedling from the Nonesuch is exclusively used in preference to any of the Paradise stocks. After many experiments had been tried, and with the experience of many years, this Nonesuch stock has been found to be the most satisfactory for promoting free yet compact growth and early fruiting. It was raised by the late Mr.

T. Rivers from the old Nonesuch, an Apple of good quality, and remarkable for its quick and regular cropping. What first attracted attention in the seedling was the formation of a number of fibrous roots at the "collar" of the stem, level with the ground or a little above it. The roots generally were also found to be very fibrous, abundant, and near to the stem, thus presenting all the qualities needed in a stock for garden trees. This was soon taken advantage of, and every experiment afforded additional proof of its value, until, as already stated, it has been found expedient to employ that and the Crab alone. Trees one year old from the bud were seen with clean, straight stems, 5 and 6 feet high; others two years old, which had been cut down the previous season, had several good branches, while the three-year-old trees were compact and handsome bushes, ready for bearing. All the best varieties were represented; but of the most popular, such as Ecklinville, Warner's King, Duchess of Oldenburgh, Ribston Pippin, and Cox's Orange, there were large breadths, comprising thousands of useful young trees. Of Pears also, on the Quince there was an excellent collection, and admirable samples of two-year-old trees were noted. Peaches like Willows, Plums and Cherries all thriving, and evidently enjoying the position they occupied—a warm slope to the south, on a retentive yellow soil.

Too much importance cannot be attached to the selection of stocks for trees, and it is unquestionably a matter that has at times been rather seriously neglected, to the cost of the planter. No after care or culture can correct a mistake in this respect, and if after a year or two it is found that trees are failing or becoming irregular and unsatisfactory, it means not only an actual loss in expenditure, but a loss of time that is far worse. Not long since we visited a newly formed fruit farm planted a year or two ago, and the differences observable in two series of trees from different sources were remarkable, and in one respect deplorable, for a large space was occupied with trees that showed by their erratic growth or stunted condition that the stocks had been carelessly selected or were quite unsuitable. The same varieties represented in the other trees were as even in growth and as healthy as could be wished. All were of the same age, were planted at the same time, and had received precisely the same treatment, yet in the one case probably half the trees would have to be removed and others substituted.

DWARF TREES.

At Sawbridgeworth innumerable excellent specimens of dwarf fruit trees are seen, and these constitute one of the specialties of the nursery, for Mr. Rivers has proved the advantages arising from their employment. He points to Apples, Pears, and Plums of all ages up to thirty years and more, fine healthful trees in full bearing, not occupying one-half the space that an ordinary orchard tree would do, yet giving bountiful returns. Trees that have from 1 foot to 2 feet of clear stem, then a well thinned bushlike head not exceeding 10 or 12 feet high, and consequently every part is readily reached without a ladder or steps, and the time saved alone in gathering fruit is an important consideration. For private gardens, and where land is planted in the market garden style of close cropping to utilise every foot of highly rented land, such trees are invaluable, and plenty of examples can now be seen where this has been carried out successfully.

PROFITABLE PLANTING.

It may not be out of place to give a few particulars respecting the plantation formed at Sawbridgeworth as experiments in profitable planting, particularly as they have proved to be exceptionally satisfactory. In one large division of the nursery, comprising several acres, we find Apples and Plums planted in alternate rows, 12 feet apart, and the same distance between the trees, the spaces between the rows being occupied with two rows of Black Currants, the land being kept hoed and dug. From this plantation wonderful returns are secured, the Apples including the best market sorts, and the Plums are mainly Rivers' Early Prolific, of which tons of fruit are produced every year. In another quarter of the latter, standard trees of good age, the distance between rows and trees is the same, but in a new plantation of Plums they are 6 feet apart in the rows, the latter being the full distance of 12 feet apart, thus admitting of the removal of every alternate tree when sufficiently advanced in growth, yet occupying the ground profitably in the meantime. Then we come to a quarter of upright cordon Apples in rows 6 feet apart, and 4 feet between the trees, which almost seems like crowding, yet space is found for a row of Gooseberries between each two lines of Apples. The latter have their growth pinched in summer, but are not much restricted until autumn, when they are cut hard back to the spurs in readiness for another season. Most of those examined were ten years old, in capital health, and yielding excellent crops of fine fruits.

There are, of course, the usual nursery stocks of trained trees in all stages, vigorous young trees, and others more advanced in life, but still in fine condition for planting, and Mr. Rivers gives an instance of the of the close rooting properties of the Nonesuch stock in the case of trees of Cox's Orange Pippin which, after remaining in one place for fourteen years, and not root-pruned, were safely removed, and are now, at twenty-four years of age, still in full bearing. Trees seven or eight years old are frequently removed. But we must turn to another department of the Sawbridgeworth Nurseries, and one for which they are widely noted—namely,

THE ORCHARD HOUSE.

Structures of this kind have caused a good deal of horticultural contention; they have been highly praised by some and condemned by

others, yet the undisputed fact remains that in many establishments they are not merely useful adjuncts to the ordinary arrangements for fruit supply, but also a source of considerable profit. The Messrs. Rivers, both father and son, have amply demonstrated the success of this phase of fruit culture, and the example set has been widely followed, not only by amateurs but by the trade as well. For Peaches and Pears they are especially useful, but some grand Apples are produced by trees in pots in such houses as the leading exhibitors know full well.

It is surprising to what a length of time trees will continue in health and bearing condition with an annual potting and top-dressing such as they there receive, for trees of the old English Galande Peach are shown thirty-eight years old. Then, too, with the numerous seedling varieties of Peaches raised by Messrs. Rivers a long fruit-bearing season is secured from the beginning of July until the end of September, three full months, such as at one time could never have been expected. The size and quality of Peaches and Nectarines thus secured are excellent, and from the numerous long spacious houses occupied with the trees most valuable crops are obtained, realising "top" prices in the market. Houses of this character cost little more than a good shed, yet if well managed they give returns surpassing those of much more costly houses. One point is, however, too frequently overlooked in regard to pot trees in orchard houses—*i.e.*, satisfactory results must not be expected without corresponding attention. Trees under glass necessarily require more care than they do out of doors. Neglected insect-infested trees are deplorable objects and utterly useless; healthful, cleanly trees will compensate their cultivator with liberal returns.

But I must stop, for some of my jottings at Sawbridgeworth will keep for another week, and they might encroach too much on the Journal's space if dealt with now.—POMONA.

THE VEGETABLE GARDEN.

[A paper read by Mr. A. Pettigrew at the meeting of the Cardiff Gardeners' Association October 2nd, 1889.]

It requires some forethought and perseverance on the part of the cultivator to keep up a regular supply of good vegetables throughout the year. To accomplish this and be successful, he must be always looking forward, and be preparing ground, as soon as it becomes vacant, for certain crops, which must be sown or planted in good time to get the best results. When crops are put in late, no matter how good the after cultivation may be, they never do so well as those planted at the proper time. It is wonderful the effect that even a few days late planting or sowing makes on a crop. Observe, for instance, that where plants have died in the main crops of, say, Brussels Sprouts, Cauliflower, Cabbage, or Broccoli, after planting, and their places been filled up by fresh plants, they seldom make up in those that were planted at first, and generally do very little good.

The weather must be studied too, and no crops put in unless the ground has been thoroughly prepared and is dry and in good working condition. It is a mistake to work ground when it is wet and adhesive; and the crops then, as a rule, never do so well as those put in when the ground is dry.

The subject of vegetable gardening is too extensive to do justice to in a short paper like this. It is a subject that volumes have been written on, and it is not exhausted yet. There is much to be learned from books on the cultivation of all kinds of plants, but I believe the best learning any young man can get is from practical experience and by ocular demonstration. Anyone with ordinary ability can learn as much in five minutes, from being told and shown how to do a thing, and the results that will follow from doing it explained, as would take him a long time to learn from books.

Winter is the dull time of the year, when Nature is supposed to rest and recuperate herself. But there is not much rest in a garden at any season, as work of some kind requires to be done regularly all through the year. In winter the gardener prepares for spring and summer; and in summer he prepares for autumn and winter, and so on, as the seasons roll round.

Perhaps I should state that kitchen gardening in the north is different in many respects from what it is here. In the north the seasons are later, the climate is much colder, and the summer is shorter; and on that account they seldom take more than one crop off the same piece of ground in the year; whereas in the mild climate, as soon as one crop is taken off another is put in, and the ground is always under crop, with perhaps a few exceptions where late Peas, Potatoes, Beet, Onions, and Carrots have been. It is a common thing in the north to have more than the half of the kitchen garden dug or trenched during winter for frost and snow to disintegrate and ameliorate the soil, and to kill insects. I question very much, however, if the frost kills as many of the insect pests as it gets credit for, even in exceptionally severe winters. Nature has provided them with ways and means of protecting themselves from the hardest of frosts.

From the above remarks it will be observed that a calendar of garden operations for a kitchen garden in the south would not do for one in the north, and my remarks will be confined to gardening in the south.

Digging and Trenching.—These are important matters, and should receive the best attention of the workmen. When dung is used it should be spread regularly over the surface, and dug deeply into the earth, and the ground kept level all over, no matter whether it is rough digging to stand over the winter, or fine digging in spring for sowing or planting. Nearly all the writers that I have read on the subject, if I remember rightly, but it is long since I read up the subject, recommend that all the bare ground in the garden not under crop should be trenched or dug in the autumn with the view to its getting the full benefit of the winter frosts to operate on it, and to make it work well in the spring. The frost, no doubt, is beneficial to heavy retentive soils, but I do not think it does much good to dry light ground to have it turned up in autumn, and exposed to all kinds of weather during winter.

My observation and experience lead me to think the harder and firmer light soils are kept the better crops they will yield, and in my opinion most crops do best when the ground is manured and dug immediately before planting or sowing, not only light ground, but most kinds of ground. When this plan is adopted the ground is trod firmly all over after it is dug before planting or sowing in it. In light soils rough fresh stable manure is preferable to decayed manure. It lasts longer in the ground in this state than if it was decayed, and supports the plants better through the growing season. In heavy soils decayed manure is best, as rough dung takes longer to decompose in it, and get into the state that plants can assimilate it in their growth.

Sowing and Planting.—The mistake of sowing seeds and planting too early in the season is as bad as sowing and planting too late. When Celery, Leeks, and many members of the Brassica family are sown in heat too early, they run to seed and the crop is lost. Potatoes when planted too early are liable to be injured by frost, and Peas suffer from cold and wet and the ravages of birds and slugs.

Onions, Leeks, Parsnips, Peas, Broad Beans, Spinach, Lettuce, and Radish should be sown in the open as early in February as the state of the weather will admit, and Jerusalem Artichokes, Shallots, Garlic, and Potato Onions planted. I think it is hardly worth while saying that Onions, Parsnips, and Lettuce should be sown in drills, the former a foot apart, and the two latter 18 inches, and not more than from 2 to 2½ inches deep; Beans 2 feet, and Peas 5 and 6 feet apart. Jerusalem Artichokes should be planted in drills 2 feet apart, and from 5 to 6 inches deep. Garlic, Shallots, and Potato Onions a foot apart, and 6 inches in the drill. In planting these I prefer covering the bulbs to having them planted on the surface, as when so planted they are liable to throw themselves out of the ground when they begin to grow and have no top pressure to keep them down until the roots take hold of the earth. When seeds are good and can be relied on thin sowing should be adopted, and Onions should never be sown so thick as to require thinning for the principal crop. If extra large specimens are wanted for exhibition purposes that is a different thing, but those are generally sown in pans and boxes under glass early in the season, and potted off into small pots, hardened off, and planted out after all danger of frost is past. Of vegetables none but the best strains should be grown. It is as easy to grow the very best varieties as the worst, and cultivators cannot be too careful in their selection of seed. The loss in every way from the use of bad seeds can hardly be over-estimated.

A long article might be written on the cultivation of each of the vegetables I have named, but I will content myself by giving a calendar for the sowing and planting a few of the principal crops in each month.

March.—This month is reckoned the end of winter and beginning of spring. It generally "comes in like a lion, and goes out like a lamb." March and April are the two busiest months in the garden. The main crops of some of the principal vegetables should be sown from the beginning to the end of the month, such as Cabbage, Cauliflower, Brussels Sprouts, early Carrots, Turnips, Radishes, Lettuces, Beans, Peas, and Spinach. The Brassica family should be sown in beds 3 or 4 feet wide in a warm sheltered position, and protected from birds, which are fond of the seeds just as they germinate, and would soon destroy them if they were not protected. I have seen many methods tried for this, but I prefer covering the beds with netting to all other kinds of protection. Horseradish, Rhubarb, Chives, Seakale, and Cabbage plants may be planted any time during the month in fine weather, and all spare ground dunged, and dug as soon as the crops are taken off.

April.—The weather during this month is generally stormy, inter-

persed with gleams of sunshine, rain, hail, snow, and frost. The remainder of the principal crops should be sown now from the beginning to the end of the month. Asparagus, Beet, Turnips, Carrots, French and Scarlet Runner Kidney Beans, Vegetable Marrows, Salsafy, Scorzonera, and Broccoli, and a succession of Beans, Peas, Lettuce, and small salading. Plant Cauliflower, Onions, and Leeks that have been raised early and protected in frames.

Towards the end of the month keep the hoe busy going through crops in drills to kill weeds, and keep the surface of the ground fresh and clean. Hoeing in dry weather between vegetable crops is a great factor in their successful cultivation, and is constantly practised by the best growers, even when no weeds can be seen. Stake Peas, and mould up early Potatoes as soon as they require it. Dress Asparagus beds, remove all winter protection from Globe Artichokes, and make new plantings if necessary of them and Rhubarb, and keep walks and everything clean and tidy.

May.—Vegetation makes great progress during this month, and, as recommended, the hoe should be kept going regularly through the different crops to kill weeds, and to keep the ground clean. Sow successions of Beans, Kidney and Broad, Peas, Radish, Lettuce, Spinach, and transplant Celery in trenches, and Leeks in drills.

June.—The weather is sometimes cold in the beginning of this month, but as the longest day approaches vegetation makes great strides. I have observed, however, in some seasons there was very little growth till after the longest day, when all kinds of vegetables made rapid growth.

A sowing of Peas may be made in the beginning of the month for the latest crop, and a succession of Turnips, Lettuces, Radishes, and early Carrots for autumn use. Plant Cabbages, Cauliflower, Broccoli, Savoys, and all the Brassica family. Stake Peas and Runner Beans. Hoe, weed, thin out crops, and keep walks and crops clean, and everything in the garden in good order. Some gardeners recommend watering crops in dry weather, but I do not, as a rule. In planting all kinds of the Brassica family I prefer dipping the roots of the plants in what gardeners call a puddle, and I can thoroughly recommend it to those who do not practise it. The puddle is easily made by scooping out a little hole in the ground near where the planting is to be done, and filling it with water. Add a handful or two of soot, and stir the earth and it in the hole till it becomes as thick as cream. Dip the roots of the plants in this, and sufficient of the puddle will stick to them when planted to carry them on without further assistance till they are established, and, to use a gardening phrase, they will withstand severe drought, "and never look over their shoulder," not flag even in the driest and hottest weather. Besides puddling the plants (which I do in all seasons) when the weather is dry and hot, it is a good plan to draw drills before planting, and make the holes for the plants, and fill them with water from a garden watering pot, and in the operation run in sufficient of the fine dry soil from the surface to leave the hole full after the water has subsided. When the earth has settled sufficiently in the holes the plants may be put in and made firm, and in doing so no hole or sign of the dibble used in planting and making them firm should be left. I dislike greatly to see a hole by the side of a plant made by the dibble in pressing the soil firm against it. No one with any taste and an idea of the harm they are doing to the plant will leave an open hole by its side. Either of these methods of planting does away with any necessity for watering the plants afterwards. In my experience watering does very little good except in extreme cases. The more you water the more you may if it is once started, and it takes up a great deal of time to little purpose.

July is generally a very hot month, but we have mostly plenty of rainfall here during the whole of it. Sow early Cabbages about the end of the month to come into use in the spring, winter Spinach, Endive, Lettuces, and Turnips, and keep us a supply of small salading. The general work in the garden during July is weeding, thinning crops, and keeping them clean and free of weeds.

August.—Sow Lettuces for autumn and winter and spring crops; Onions, Turnips, and Cauliflowers to stand the winter in frames. Earth-up Celery, and lift and store away Shallots. The same routine of hoeing, weeding, and keeping crops clean as was done last month must be attended to. Remove all decayed leaves and stumps of Cabbage and Cauliflower that have been cut, which become unsightly if left in the ground.

September.—Plant Cabbage and Lettuce, to come in use in the spring; Harvest Beet, Carrots, Onions, and Garlic; earth-up Celery, and remove all decayed vegetation; and prepare for winter by cutting some of the best of the Cauliflower in case of frost, and store them away in a dark

cellar. If the stems are inserted in wet sand they will keep fresh and crisp for a long time. Prepare Seakale and Rhubarb for forcing. From this date on till the beginning of the year the principal work in the garden will be manuring and digging ground. By the end of the month or early in October cover up Asparagus beds with good manure, and protect Globe Artichokes and other plants from frost. Repair and keep walks clean and in good condition, and attend to a host of other little odds and ends, which make up a successful whole in the cultivation of the kitchen garden.

HARDY FRUIT AT EXHIBITIONS.

THE remarks in last week's *Journal of Horticulture* seem to call for an answer from us as large exhibitors of highly coloured Apples. You may be surprised to know that in the 600 fruits of Apples exhibited by us at the Crystal Palace in the champion class (first prize), only thirty-six fruits were from under glass; and in order to show how little weight these thirty-six had, we might mention that in several cases—Cox's Orange, Queen, Dutch Mignonne, to wit—three fruits were from the open, and three from under glass. As these dishes were duly matched, you may perhaps be convinced that our grand soil will turn out clean and coloured examples when carefully tended by our foreman, under whose care they are. We are quite content to show entirely from the open, and you will perhaps oblige us with space to refute the erroneous notion that we are deceivers of the public.—GEORGE BUNYARD & CO.

[We are not in the least "surprised" to learn that so few under-glass fruits were included in the collection indicated, and require no "convincing" that Kentish soil and climate will produce clean well-coloured fruit. Messrs. George Bunyard & Co. may therefore well be "content to show entirely from the open," and we are glad to find they give their adhesion to the proposed change, which the majority of nurserymen and amateurs desire to see adopted. After the very precise statement on page 325—namely, "No one for a moment suggests that the inclusion of glass-aided Apples and Pears in collections of hardy fruit is done with the intention of misleading visitors," the last observation of Messrs. George Bunyard & Co. appears somewhat remarkable, and not the less so since we further stated that "nothing of the kind (suggested) is intended by exhibitors." We thought those sentences were only capable of one interpretation, but our correspondents seem to have discovered another, and the public must judge between them.]

CULTURE OF CYCLAMENS.

[Abstract of a paper read by Mr. Walker at the Paxton Society's meeting, Rothwell, West Yorks.]

It is my object in the following short essay to state as clearly as possible my experience, with the object that it may be of benefit to my fellow gardeners and others who are interested in this beautiful plant. I am sorry to say that it is not cultivated so much in private places as it should be. I know from experience that it is not an easy plant to grow; on the contrary, for it requires strict attention from the seedling stage onwards. The system I adopt differs considerably from any I have seen described in the horticultural papers, and previous to my adoption of this I had no satisfactory results.

Success will greatly depend upon the time the seed is sown, and the proper time will be as soon as the seed is ripe—namely, July, August, and September, the two former months being the best. The seed may be sown as late as January, but the results would not be so satisfactory. Sow in pans in a compost of rough sandy loam and leaf mould, well draining the pans, and not filling them, adding half an inch in depth to the same mixture finely sifted on the top. Press firmly and water with a fine-rose pot, so that the whole is moistened; when dry enough the seeds may be sown on the surface and pressed in lightly instead of scattering soil over them. Place a piece of paper over the pan, also a square of glass, until the seeds germinate, then remove the paper, allowing the glass to remain. Shade from hot sun until they form roots, and when this is accomplished gradually bring them to the light. When the young plants are about an inch long they should be pricked out into pans or boxes in the same kind of compost as already recommended. Ventilation must be provided during the early part of the day, and they should also be slightly syringed two or three times daily.

When the weather becomes colder it will be necessary to remove them to a warm house, and, above all, place them as near the glass as possible; the temperature should be from 45° to 50°, where they may remain until the middle of April or the beginning of May. By that time it will be necessary to plant them out in a bed facing east, made of materials similar to a Cucumber bed, or any half-spent manure will do, for it is not necessary to have it hot. Cover the surface with a compost of loam and leaf mould to the depth of about 6 inches, made firm, so that when lifting time comes the plants will be taken up with a good

ball of roots. They may be planted in rows 6 inches apart, so that when they begin to get crowded every alternate row may be lifted and transplanted as stated above. It is necessary that each plant should have ample room, and at the same time take care that the corms be well out of the soil.

The reason they are placed in an eastern position is that in the early stage of growth, and after being slightly dewed with a syringe, the frame can be closed much earlier. It should be understood that they require shading during hot weather to prevent flagging, with slight ventilation late at night. By this treatment they commence flowering early, but it is necessary and safer to remove all the flowers until the plants are established. Green fly and red spider must be kept in check, or they will injure both leaves and flowers.

The treatment given may be continued until September, when lifting and potting will be necessary. This should be done with care using no larger pots than are absolutely necessary to get the roots into, as they do not make much root either before potting or after. Keep them well up in the pots to avoid water standing on the corms, for if allowed to be left in that state some will damp off. When potted place them in a close frame, keep them near the glass, shade from hot sun for a few days, frequently syringing, and on dewy nights the lights can be drawn off. When they are established in these pots the lights are drawn off in bright sunny weather and the plants syringed several times a day, and by so doing they never flag. Close the frames about three o'clock in the afternoon, and open them about six or seven o'clock, according to the weather. By this time the plants will commence throwing up a few flowers, which will be found useful. As the weather becomes too cold for them to remain in the frame remove them to any suitable house at command with a temperature of from 45° to 50°. Avoid a damp atmosphere; plenty of air must be admitted when the weather permits, and a little fire heat can be given with care. The leaves and flower stems are liable to damp near the corms, and when such is the case a little sulphur placed upon the affected parts will prevent its progress. When the flowers are wanted for use they should be pulled out, not cut, as the pieces left (if cut) decay and affect those remaining. I have large plants grown in this way, which commence flowering early in November and continue until May. I also find that the early sown plants flower longer and later, producing more and better flowers.

A word respecting the old corms. I find from experience that they are not worth the trouble of growing, for they come into bloom so late and they are not nearly so productive as young ones. Too much cannot be said in praise of the Cyclamen as a decorative plant; it has a fine appearance when grown well, the flowers are conspicuous, and the foliage beautiful.—R. KIRBY, *Oulton Hall*.

HONOURS IN HORTICULTURE.

I HAVE read with much interest the letter of Mr. Wright in your issue of the 10th, and I agree with all that he says concerning the R.H.S.

The ambition of the Council is to make the Society a representative National Society for the whole of England, but in my opinion they will never succeed in this until they determine to cultivate more assiduously the affections of all sorts and conditions of horticulturists. In their fortnightly shows, in reviving the Journal, and in their gratuitous distributions of seeds and plants, they have done much to make the Society attractive; but in their distribution of honours, at their general meetings, and in the composition of the Council, they show to my mind that the wealthy amateur with miles of glass and armies of gardeners, and the leading nurserymen, are the two classes of supporters they mainly affect. They do not seem to realise that the vast majority of horticulturists is not to be found in either of those two classes.

I have been an amateur horticulturist all my life, and became a F.R.H.S. in consequence of the appeal of the Council in 1887, and last year I was induced to become an exhibitor in a small way at its Temple Show. I received every attention, assistance, and courtesy from the Superintendent and his able assistants; but I was most effectually suppressed and my exhibit driven into an obscure corner by the enterprising nurserymen by whom I was surrounded. The official card describing my exhibit was removed by someone each day, and it seemed evident to me that I was regarded as an intruder not to be encouraged. It will be long, therefore, before I again exhibit at any show of the R.H.S., especially as I myself agree that I was an intruder, and that the shows, as now conducted, are designed for the wealthy amateurs and leading nurserymen, and not for the more humble amateurs, who nevertheless have done much service to horticulture, and without whose custom many nurserymen would find it difficult to exist.

I have urged these views both by letter and by speech at the last general meeting of the Society, but without much apparent effect; but if you open your columns to a discussion on the subject it may possibly

aid towards enlarging and improving the R.H.S. and placing it in the position in which, as I have said, it is the laudable ambition of the Council to place it.—FRANK R. PARKER, *Kynaston Lodge, Harrow Weald*.

[We insert this letter, though we know it is impossible for exhibitors to choose and retain positions at a crowded show.]

At a general meeting of the ROYAL HORTICULTURAL SOCIETY, held October 22nd, in the Drill Hall of the London Scottish R.V., James Street, Westminster, T. Francis Rivers, Esq., in the chair, the following candidates were duly elected Fellows—viz., Rev. Charles G. Auderson, Walter F. H. Blandford, B.A., Mrs. Brice, James E. Burrell, John Chivers, Mrs. Christie, Mrs. R. Codd, George Evans, Hugh Goodman Roberts, George Taber.

— CHISWICK GARDENERS' ASSOCIATION.—We are desired to insert the following reminder:—"A concert will be given under the auspices of this Association in aid of the Gardeners' Orphan Fund, on Thursday, 31st inst., in the Vestry Hall, Chiswick. Those readers who happen to be in the neighbourhood on the date mentioned may feel inclined to support this worthy project. Tickets of admission, 1s. (reserved and numbered seats, 2s. 6d.), may be obtained by applying to Mr. J. Barry, R.H.S. Gardens, Chiswick."

— GARDENERS' ROYAL BENEVOLENT INSTITUTION.—We are requested to announce that the annual card collection for this year will close on the 31st inst., and the Secretary will be glad to receive any outstanding cards on or before that date. We are pleased to learn that the collecting cards have this year brought in a clear net sum of about £980.

— ON the evening of Wednesday, the 16th inst., MR. HARRY J. VEITCH of the Royal Exotic Nurseries, Chelsea, was entertained at a complimentary dinner at the Grand Hotel, Trafalgar Square, the chair being occupied by Baron H. Schröder. About sixty gentlemen were present, including Rev. W. Wilks, Mr. T. B. Haywood, Mr. Philip Crowley, Dr. Hogg, Mr. Shirley Hibberd, Mr. George Deal, Mr. Bunyard, &c., &c.

— VEITCH MEMORIAL MEDALS AT THE EDINBURGH SHOW.—I was surprised that the Royal Caledonian Society did not make more of these at their recent Show. Two of them were awarded, but there was nothing on the exhibits to indicate to the public the importance of the competition. I saw a reporter on an Edinburgh daily paper attach himself to Mr. H. J. Veitch, seek for information, and he appeared inclined to congratulate Mr. Veitch on his liberality, until that gentleman explained he had no personal interest in the prizes; but in my opinion it would only have been an act of courtesy on the part of the Council to have provided two special cards, containing some intimation of the original and present position of the Memorial awards.—PRACTITIONER.

— THE BLACK HAMBURGH GRAPE.—From his peculiar note, page 338, it is not clear what "Fifeshire" requires of me; but since he mentions my name, let me assure him he need not count on my support if he is going to attempt to prove that the Black Hamburgh is as well grown now as it was twenty years ago. The quantity seen, and the prominence given, to purely midwinter Grapes in all shows and markets, from midsummer onwards, induces me to join conscientiously with "A Kitchen Gardener" in his laudatory remarks in discovering an exceptionally fine crop of this most meritorious Grape, as well as in his lamentations over the undoubted decrease in popularity of the old Black Hamburgh.—J. MUIR.

— NICOTIANA AFFINIS AND N. LONGIFLORA.—They are not the same. *Nicotiana longiflora* is a much better flower than *N. affinis*, being purer white, with a smaller tube. The flowers close up but very little in the daytime, and are very fragrant. I grew and exhibited *N. longiflora* about seven years ago, and it was very much admired. I subsequently lost it, and have not been able to secure it since, although I have tried to get it from several seedsmen; but this autumn, while

paying a visit to the old village of Woodbridge in Suffolk, I saw it in several of the cottage windows. I have been given to understand it was introduced some years ago by Mr. Thompson of Ipswich.—C. HOLDER, *Reading*.

— GARDENING APPOINTMENT.—Mr. W. J. Holden informs us that he has been appointed head gardener to C. A. D. Halford, Esq., West Lodge Gardens, East Bergholt, Suffolk, post town Colchester.

— A CORRESPONDENT ("J. L.") desires to know which is the BEST PINK GERANIUM (*Zonal Pelargonium*) FOR BEDDING. As this is very much a question of taste, not uninfluenced by local circumstances, we leave the matter open to those flower gardeners who may be disposed to do so to communicate their experience. Our correspondent mentions Mrs. Turner approvingly, but has been informed it has been excelled by another, the name of which we cannot decipher.

— YOUR correspondent "A. C.," page 327, speaks of "the solid stiffness of that best of travellers the STAR OF WALTHAM" Rose. I once carried a half-expanded bud of this Rose in my travelling portmanteau over 1000 miles, taking it out and putting the stalk in water every night for four nights. On the fifth day, although then expanded, it would bear looking at.—WM. PAUL, *Waltham Cross*.

— AT the meeting of the LINNEAN SOCIETY OF NEW SOUTH WALES on August 20th Mr. J. H. Maiden read an interesting paper on *Spinifex resin*. The resin examined was a sample obtained by Mr. W. Froggatt near Derby, North-west Australia, last year, and presented by Sir William Macleay to Mr. Maiden. It is in flat cakes, about 3 inches in diameter, has a dirty bronze-green appearance, and a persistent disagreeable odour not easily described. It consists of vegetable *débris* (which may prove to belong to grass) cemented with a yellowish-brown resin, and containing about 3 per cent. of fat. Mr. Froggatt states that it is employed by the natives as a cement for spear-heads, &c.; and the consistent testimony of the natives, as well as of the Europeans, is that it is obtained from the roots of *Spinifex Grass* (*Triodia irritans*, *P. Br.*). As far as the author knows the extraction of resin from a grass has never previously been recorded. The resin isolated bears no resemblance to any other Australian resin known to the author.—(*Nature*.)

— IN his last report to the Foreign Office on the AGRICULTURAL CONDITION OF COLOMBIA the British Consul at Bogota says that the Potato is the chief food of the people of the cold part of that country. Two principal varieties are known—namely, the Criollas, which are red-skinned and orange-coloured inside, and the ordinary white Potatoes. In 1865 the Potato disease, which was unknown till that year, attacked the crops, and they have decreased very much in quantity since then. It is worthy of remark that the greater the altitude at which Potatoes are planted (they are sometimes planted at a height of above 9000 feet on the mountains) the less tendency is there for the disease to break out, and at the greatest altitudes the disease is almost, if not quite, unknown. With regard to the Cinchona industry the Consul reports that in 1884 the Government of the Republic passed a law for the purpose of promoting the plantation of Cinchona, India-rubber, and Eucalyptus trees, and the President was authorised to award valuable prizes to the most successful growers of Cinchona trees. The trees to be planted were to be of four species, *C. Ledgeriana*, *C. officinalis*, *C. lancifolia*, and *C. pitayensis*, but, though the distribution of trees was free, the law has remained a dead letter; no new plantations have been made under its provisions.

— PROPOSED TESTIMONIAL TO MR. W. DEAN.—The following circular has been issued:—"It has been thought by many horticultural friends that Mr. W. Dean (late of the Mill Hill Nurseries, Solihull, Birmingham) having spent nearly fifty years of his life in useful horticultural work, and is now in declining health, that a fitting time has arrived for recognising the valuable services he has rendered to horticulture, notably amongst these being the founding of the National Floricultural Society, which for a time did much valuable work amongst florists' and other flowers, ultimately merging into the Floral Committee of the Royal Horticultural Society. He was one of the 110 Judges at the Great National Exhibition held in London in 1866, in addition to which he has for many years acted as judge at flower shows at York, Dublin, Edinburgh, London, Newcastle-on-Tyne, Shrewsbury, and many other places. He was the first to introduce the Fancy Pansy to this country, which is now one of the most popular flowers of our gardens, and was at one time joint Editor of 'Gossip of the Garden' and Editor of 'The Florist Guide,' in addition to which he has been a frequent contributor to other gardening periodicals for more than thirty

years. These, and other services too numerous to mention, have contributed so materially to the advancement of horticulture that we, the undersigned, think it most desirable that his friends should have an opportunity of showing their appreciation of such valuable services. Contributions will therefore be most thankfully received and acknowledged by any one of the undersigned:—W. B. Latham, Curator, Botanical Gardens, Edgbaston, Birmingham; Walter Jones, Stephenson Chambers, New Street, Birmingham; W. Spinks, The Nurseries, Solihull, Birmingham; R. Johnson, Springfield, Drury Lane, Solihull, Birmingham; James Bubb, High Street, Solihull; and J. Hughes, Northwood Villas, Mitchley Lane, Harborne, Birmingham, Secretary *pro tem*. Contributions will be received up to November 1st, when the list will be closed, and the amount duly announced."

SHORTIA GALACIFOLIA.

ON page 273 of this Journal, April 4th, 1889, we find an illustration and description of the above-named plant, and in the October number of the "Botanical Magazine" a coloured illustration appears together with the following particulars by Sir J. D. Hooker:—

One of the most interesting of North American plants is on account of its history, its great rarity, and of the geographical distribution of the genus to which it belongs, which consists of only two species, the present and an almost undistinguishable congener, a native in Japan. *Shortia* is thus one of the most striking proofs of that kinship of the floras of Eastern Temperate Asia and Eastern North America, to the exclusion of Western America, through the study of which Asa Gray has thrown so much light on the past history of the vegetation of the northern hemisphere.

The following history of *Shortia galacifolia* is from the pen of Professor Sargent, as published in the "Garden and Forest." "The great interest of *Shortia* is found in the history of this plant during the past century, and in the fact that of all the plants studied and described and classified by Asa Gray, this little herb most excited his interest. . . . Professor Gray was in Europe in 1839, and when examining the herbarium of the elder Michaux, preserved in the museum at Paris, he found an unnamed specimen of a plant, with the habit of a *Pyrola* and the foliage of *Galax*, of which only the leaves and a single fruit were preserved, and which had been collected, the label stated, in the Hautes Montagnes de Caroline. This specimen at once arrested his attention, and after his return two years later from his first botanical journey in the Carolina Mountains, where he had searched in vain for Michaux's plant, he ventured to describe it, and to point out its probable affinities, dedicating it to Dr. C. W. Short, the author of a catalogue of the plants of Kentucky."

"Nothing more was seen of *Shortia* for a long time, although no botanists ever visited the mountains of Carolina, and the number in 1866 was considerable, without carrying a special commission from Cambridge to bring back a specimen of Michaux's little plant, in which Dr. Gray's interest became stronger than ever, when, studying in 1858 a collection of Maximovicz's Japan plants, he recognised in that botanist's *Schizocodon uniflorus* another species of *Shortia*, also identical with the Carolina plant. These specimens, while they confirmed the validity of the genus, threw no further light on the Carolina plant, which botanists now hunted for more assiduously than ever in all the region in which Michaux was supposed to have travelled."

In fine, "the search was given up as almost hopeless, when in May, 1887, *Shortia* was found accidentally by a youth upon the banks of the Catawba river, near the town of Marion, in McDowell county, N. Carolina, at a considerable distance from the high mountains to which Michaux's label assigned the plant."

Professor Sargent then proceeds to give an account of his own re-discovery of *Shortia* in Michaux's original habitat, to which he was led for the purpose of gaining some insight into the origin of Michaux's *Magnolia cordata*. It was during a journey of Michaux's to get roots of this latter plant that he visited the head waters of the Keowee, and though weakened by sickness and hunger he proceeded to explore the mountains. On the day of his arrival he discovered what he called a *nouvel arbuste a. f. dentelés rampant sur la Montagne*. Reading Michaux's MSS. Journal, preserved in the Library of the American Philosophical Society, this note of Michaux's interested Professor Sargent, and he determined to hunt for the arbuste as well as for the *Magnolia*, little suspecting what the former would prove to be. After finding the spot where Michaux had camped in December, 1788, and following a path that the old traveller must have traversed just 100 years before, he discovered the arbuste with denticulate leaves, and this to be no other than *Shortia galacifolia*.

Soon after the re-discovery of *Shortia* by Mr. Hyam, it was widely distributed in America; for, as Professor Sargent tells us, "that enterprising young man reaped a rich harvest during a year or two by selling plants (and it is to be feared by exterminating them) at extravagant prices. The credit of flowering it for the first time in England is due to our indefatigable correspondent, Mr. Elwes, who received plants of it from Professor Sargent, and to whom the Royal Gardens are indebted for that here figured, which was exhibited at the Royal Horticultural Society's Exhibition in the spring of this year. Plants of it have also flowered at Kew, received from Mr. F. L. Temple of Shady Hill Nurseries, Cambridge, U.S.A."

As an object of garden culture *Shortia* will no doubt prove a favourite, for it appears to be easily grown and readily propagated. A specimen kindly given to me by Mr. Elwes early in this year was planted under a clump of Scotch Firs in a peaty soil near Sunningdale, and has thriven luxuriantly side by side with *Linnæa borealis* and *Trientalis europæa*. The flowers have been described as rose coloured, but they are correctly figured as pure white in Sprague and Goodale's "Wild Flowers of North America," and so they are in the specimens that have flowered in England. The leaves turn a deep port-wine red in autumn, and nothing can exceed the charm of the abundant drooping Snowdrop like flowers on red scapes as they appear amongst the deep green shining spring foliage.

COLLECTIONS OF VEGETABLES.

At the early autumn shows of horticultural societies collections of vegetables usually constitute an important feature, and when tastefully

effected, and not more than four dishes (distinct) of any sort. The following varieties were shown by Mr. Beckett, who displayed them admirably, contrasting the colours in quite an artistic manner:—Drumhead Savoy, Brussels Sprouts, Standard Bearer Celery, Golden Globe and White Spa nish Onions, Summer Favourite and Scarlet Perfection Carrots, Perfection Tomatoes, Anticipation Peas, Magnum Bonum Potatoes, Champion Runner Beans, Jersey Lily Turnip, Perfection Beet, Maltese Parsnips, Mushroom spawn, Trophy and Abundance Tomatoes, pickling Cabbage (red), Little Gem ditto (white), Scarlet Runner Bean, Canadian Wonder ditto; Autumn Mammoth, Favourite, and Magnum Bonum Cauliflowers; Blood Red and Excelsior Beet; Exhibition, The Aigburth, and Matchless Sprouts; Sulham Prize and Superb Pink Celery; New Red Intermediate and Long Red Surrey Carrots; Telegraph, Tender and True, Model and Telegraph Cucumbers; Golden Dawn, Read Giant, and Long Red Capsicum; Exeter Fine Green Curled and White

FIG. 43.—A PRIZE COLLECTION OF VEGETABLES.

arranged, as the best exhibitors invariably display them, they produce quite a pleasing and varied effect. At the Crystal Palace Show recently several classes were appropriated to vegetables, and the keen competition brought out some admirable specimens of kitchen garden produce, as well as giving the exhibitors a chance of displaying their taste and skill in arrangement. One of the best of these in all respects was that for which Mr. T. A. Beckett, Cole Hatch Farm, Amersham, was awarded a first prize, and so effective was this collection that we have had an engraving (fig. 43) prepared from a photograph supplied by Messrs. Negretti & Zambra to represent its chief characters. It has been necessary, however, to somewhat reduce the sides to admit it into our pages, consequently the corner examples of Parsnips, Turnips, and Celery are not seen.

The class was for the best exhibition of vegetables arranged for

Batavian Endive; Mammoth White Cos, White Heart, Tom Thumb Cabbage, and Marvel Cabbage Lettuces; Improved Reading and Ailsa Craig Onions; Prizetaker, Musselburgh, and The Lyon Leeks; Long Crimson, Olive Crimson, Scarlet Globe, and White Olive Radishes; Snowball and Six Weeks Turnips; Long White, Improved Green Bush, Moore's Cream, and Long Green Marrows; Cardoons; Green Globe and Jerusalem Artichokes; Mammoth Gourd, Longstanding Spinach, Giant Salsafy, Parsnip Student; Mustard and Cress; Parsley; Seedlings, Vicar of Laleham, and Beauty of Hebron Potatoes; and Giant Shallots.

RATS IN GARDENS.

IN reply to "L. K.," I may say that if a rat comes on my premises I consider it a very cunning one to live many days without putting its

foot into a trap. To just set a trap or two in the open, uncovered, is very seldom successful, but to set a trap to catch a rat one must use a little stratagem. Rats, when they settle down to a place, soon make visible runs, and are very wary about using new and uncertain ground. In the first place traps must be in good condition, so that they will go off at a slight touch on the treadle. To ascertain this, set it, and see if the catch is in the right form, very slightly bevelled outward. The strength, or weight, required to let it off may be ascertained by trying it with the thumb underneath the jaws. If it goes off hard, a rat's weight will not let it off, and it must be slightly filed and greased. Notice the most used runs, and take out sufficient ground to let the trap into the earth on a level with the run, and make up as natural-looking as possible by placing fine earth gently, and by degrees, on the treadle, and between the jaws and the treadle; at the same time see that sufficient does not work or run under the treadle to take a bearing to prevent going off. In buildings it is just as requisite to use deception to insure success. A little bran or chaff, or the soil scratched out in burrowing, is used to cover the traps and make up on a level with the surroundings. If a rat accidentally lets the trap off without getting caught, set the trap in a fresh position, as they are very wary of a second attempt.—J. HAM.

GRAPE GROWING FOR PROFIT.

THE RED ROSE VINERIES, CHESTER-LE-STREET.

IN the counties of Northumberland and Durham there is no name better known amongst horticulturists than that of Mr. Joseph Witherspoon. Primarily he is a Grape grower, and a remarkably successful one, but there are other fields of action in which his influence has been felt. Wheelwright, political economist, editor, engineer, florist, and Grape grower, Mr. Witherspoon's life has been one of more than usual variety and interest. Chester-le-Street, where the Red Rose Vineries are situated, is a quiet little town in Durham, and within a few miles of the county town, famous, a native informed me, for two things, mustard and old maids. There is a good service of trains from Newcastle-on-Tyne, southward bound, and the town once reached all else is plain sailing, for vineries and Vine grower are equally familiar to everyone. I have referred to Mr. Witherspoon's many-sided career. It is a curious fact that in the same town whence come his now famous market Grapes he commenced business life as a working wheelwright many years ago. Not only so, but a large portion of his youth and manhood were devoted to this calling. An inherent love of horticultural pursuits had, however, been growing. By-and-by it took tangible form. The first step was flowers, the second fruit, the third the final abandonment of plane and chisel in order to earn a livelihood by marketing Grapes. No doubt there were early disappointments, perhaps partial failures, but sturdy perseverance triumphed. There can be no doubt of the absorbing interest of Grape growing, and one has only to glance at the space required for dealing with the doubts and difficulties of Grape growers in the correspondence columns of this and other journals to appreciate its importance. Mr. Witherspoon proceeded step by step, acquiring experience, and digesting it thoroughly, and I believe he is satisfied, now that the third score year of his life has passed, that he is on the right path, and after seeing splendid examples of his fruit in the great fruiterers' shops at Newcastle, and long ranges of glass, bearing wonderful crops at the Chester-le-Street vineries, he would be a bold man who would declare the veteran wrong.

The first feeling of surprise is awakened on entering a house some 150 feet long to find fine crops of Black Hamburgh, Black Alicante, Gros Colman, and Gros Guillaume (miscalled Black Barbarossa) growing side by side. A few of the first named are grown, about double as many Alicantes, and about six times the number of Gros Colman. This Grape is Mr. Witherspoon's sheet anchor. He sends thousands of bunches into the market, excellent in form and colour, and thinned to perfection. No one can be surprised that the great fruit-buying public are attracted by Gros Colman more than by any other Grape when bunches are put before them perfect in symmetry, enormous in the size of the berries, and finely coloured. Gros Colman is not only the first of all market Grapes from its commanding appearance when well grown, but it comes in when the glut of Hamburgs and Alicantes is past. Hundreds of pounds are realised by the sales of this variety alone. A constant demand and the highest prices are sufficient evidence of their adaptability to market wants.

Some remarks will naturally be looked for bearing on the mode of treatment Mr. Witherspoon pursues to secure such results; as anyone may see who visits him. Perhaps he would not thank me for describing every detail of management, but there are some general principles which may be referred to. His good advice to those starting in Vine culture is—"Treat your Vines as you would a young horse that you wish to do your work twenty years hence." Overcropping Vines and overworking horses are common evils. Mr. Witherspoon fell into the former, but the lesson learned he has never forgotten. Our friend's precepts are good, his practice still better. "Sufficient without gorging" is one of the former, which he never wearies of emphasising. Healthy root-action, which means vigorous growth and fruit of the highest flavour, depends upon it. Overfeeding is waste of material, waste of labour, and waste of profit. He has a firm belief in mulching; none whatever in repeated waterings. The inside borders of the vineries whence thousands of bunches of Grapes are taken to realise the highest prices in the markets, are so dry as to cake and fly into dust if the foot

is applied to the soil. If the visitor thinks this is going to extremes he is advised to raise his head and see if the splendid clusters above speak of ill treatment or the reverse. Mulchings of cow manure are firmly believed in. Beneath cow droppings on the driest pasture moisture is always found, with sufficient sweetness for the roots to retain health; and so the manure is applied to the Vine borders at the same thickness as it is found in the fields. Horse manure is employed on the same principle, and fowl manure is used like guano. It is contended that if these quantities are doubled sour borders result, and of these the evils are many and serious. New borders are now all composed of turf, lime rubbish, and plenty of stones, especially if on a dry bottom, on the ground that no matter how dry the season may be a stone is damp and so affords moisture totally devoid of impurities. The practice at the Red Rose Vineries is to water in winter until the border is thoroughly moistened, and then to keep the mulching damp during the growing period.

Previous to thinning all shoulders are removed, and then sufficient bunches are taken off to leave what is considered to be a fair crop. Then comes the thinning, and great as the task must be in a Grape-growing establishment like this, every bunch is thinned to perfection. Sometimes a little miscalculation leads to a heavier crop than is considered desirable. For instance, five bunches of Gros Maroc intended for showing were left on a 12-foot cane last year with the expectation that they would not average more than 3 lbs. each; instead they averaged nearly 4½ lbs., or a total weight of over 20 lbs., and the result was that they did not colour so well as they would have done had the bunches been of the anticipated weight.

The Vines are restricted to single rods, and the wood is thoroughly ripened. Splendid bunches may be seen hanging close to the ground, and these are usually the best coloured. No space is wasted in these houses; besides the roof Vines there are other canes trained along the side of the path like Raspberries to a rail, bearing good bunches, if not good enough for market. With one exception there are both inside and outside borders, the latter being all raised and left uneropped. Mr. Witherspoon calls his the "warm sweet border system," and has both preached and practised it for many years. The exception referred to is a new house planted this spring, and owing to a cart road running along the front an outside border had to be dispensed with. In this house a few Vines of Duke of Buccleuch and Madresfield Court have been planted. The former is managed well, but although cracking is not feared it is considered that these varieties should have a special house if possible. In order to make the house pay its way until the Vines reach a profitable stage it has been planted with Tomatoes, and £60 has been realised by their sale. They will be grown again next year; then the turn of the Grapes will come.

Though the Grapes are chiefly grown for market purposes it is not uncommon to find their grower competing at the northern shows, and holding his own. He is also the patentee of the excellent Red Rose boiler, which, I believe, is about to be made more widely known by a newly formed company.

The general lessons to be learned from an inspection of this establishment are well worth considering. In the first place we are shown that the highest possible results are achievable in Vine culture when close attention, untiring energy, and ceaseless perseverance, directed by common sense, are brought to bear in the absence of formal schooling. Mr. Witherspoon could not be spoken of as an amateur now, but he commenced as such, and taught himself what most of his contemporaries learned in their youth from the various masters under whom they served. Were Mr. Joseph Witherspoon, or any other great grower, asked to point out to the beginner the path of success, he would impress upon him that the first essentials were planting healthy Vines in a fresh, wholesome, well-drained soil; the second, keeping them in health by ample, but not excessive, supplies of food; the third, to avoid shanked, unripe, stoneless, or otherwise imperfect fruit by judicious cropping; the fourth, to insure perfect ripening and subsequent abundant crops by a thin disposal of the foliage. These are looked upon as points of paramount importance at the Red Rose Vineries. Heavy crops are secured, at least more than an ordinary weight of fruit, from a given area, but the rods are not overloaded; they are grown somewhat more closely together than in most establishments. The drain upon the root medium is, of course, proportionately great, but the "warm sweet border" system has never yet failed.—W. P. WRIGHT.

BULLFINCHES.

A TIMELY HINT.

I THINK it is about ten years since I gave some particulars in the Journal respecting catching and keeping these birds. I would remind fruit growers that the time of year has arrived when these birds are very easily caught in trap-cages instead of shooting them later on. I have taken eleven out of a trap-cage in my garden within the last week, and I expect to take scores between now and Christmas, after which it is difficult to get one into a trap. Within the past ten years I have trapped hundreds. They vary much in number in different seasons. I fancy we have an influx with our winter migratory birds, as I have noticed many during the past few days flying very high, and they may be fetched down from a height of 100 yards by imitating their well known call note. Last season I only caught twenty-three; in the autumn of 1887 I took sixty within a few yards of the house door. I

made 2s. 6d. each of the cocks in spring, which paid better than wasting powder and shot and spoiling fruit trees by shooting into them.—J. HIAM.

CHRYSANTHEMUMS IN HAMPSHIRE.

DURING the past few years the establishment of Messrs. W. & G. Drover at Fareham has become well known for the cultivation of Chrysanthemums for exhibition. Yet it cannot be said that their conveniences are of the best kind for the summer growth and autumn flowering of the plants. The space for the former is limited, and for the latter use is made of Rose and other houses, wherein numerous other plants are grown during the summer to meet the cut flower demand. Last year the members of this firm succeeded in carrying off the handsome silver claret jug value £25 and a cash prize of £6 given by the Portsmouth Chrysanthemum Society with a splendid stand of blooms. This prize they have to win again, which will be their main object this year. Judging from the appearance of their 600 plants at the present time they will, to use exhibition phraseology, be hard to beat. The growth this season is tall, especially in the "Queen" family and Princess of Wales. It is to the latter only the exception can be taken on account perhaps of "softness." The plants are strong, well furnished with leaves and buds, which are opening "kindly" and devoid of coarseness. The present bright weather will do much toward bringing on the late plants, which will need all the time available to insure perfect development by the required dates. The varieties most promising at the present time are Boule d'Or, Golden Dragon, very fine; Ralph Brocklebank, Jeanne Délaux, always good here; M. W. Holmes, M. Freeman, Avalanche, very early; Novelty, most promising; Refulgence, Jardin des Plantes, rich; Lord Alcester, and John Salter. Several new French raised varieties are on trial, which by their present appearance do not promise anything extraordinary.

ROOKSBURY PARK.

In the Chrysanthemum world this is a new name, but the name of the cultivator there is not new, for he is a younger brother of Mr. Molyneux of Swanmore Park, who is looking forward, no doubt anxiously, to making his *début* as an exhibitor on his own account; and as he has had much experience in this when at Swanmore, where he served as foreman six years, the "business" will not be entirely new to him. Circumstances at present do not admit of his growing a large number of plants, neither is the convenience for housing the plants quite of the best. Most of the plants are standing in a large and lofty conservatory adjoining the mansion. In this position they are far from the glass. The roof is 30 feet high, although through the side they obtain ample light. The plants are arranged in a sloping bank 100 feet long, and being backed up with specimens of Camellias nearly 20 feet high and other plants which reach the roof, an excellent effect is produced by the glowing colours against the dark green background. One thing which specially struck me was the intensity of the colours. Princess Beatrice, for instance, was a true rose pink, not that washed-out lilac tint so often seen. The plants are not so much characterised by a great thickness of stems as they are by their complete maturation. This and a hilly situation may have much to do with the intensity of the colours. Many varieties are now expanding their blooms, and are evidently well "timed." Especially good was the promise of blooms of such varieties as Prince Alfred and its sport Lord Wolsley, which are already deeply built, an essential point of quality. Novelty, capital; Refulgens, fine; Princess of Wales and Mrs. Heale, very good; Lady Hardinge, Mrs. W. Shipman, and Jardin des Plantes were conspicuous amongst the incurved varieties. Japanese were represented by large expanding blooms of Frederick Marrouch, a deep orange yellow, capital for back lines; Belle Paule, equally good; Baronne de Prailley, Sunflower, Ralph Brocklebank, substantial blooms of Avalanche gradually developing, and later ones of Edwin Molyneux and M. Astorg, the latter a silvery white, in which the florets have an elegant drooping character. Taken as a whole the prospect is encouraging, although Mr. N. Molyneux is anxious to see how the blooms will develop in such roomy and lofty quarters.

SWANMORE PARK.

A note respecting the prospect of the Chrysanthemum season in Hants would hardly be complete without a mention of the Swanmore plants. Mr. Molyneux, by the publication of his book, has done much in extending the growth of Chrysanthemums for the production of large blooms, and although he is not such a prominent exhibitor he is still a large grower, turning his attention to bringing out the latent qualities of new varieties. For example, the finest of all the white varieties of the Japanese section, Avalanche, first expanded there in its proper form two years since. Last year brought out another sterling novelty, Mrs. Falconer Jameson, this, like the former, being one of Mr. Cannell's seedlings. This season proves the variety to be one of the best of its colour and kind in existence, coupled with dwarf growth, 3 feet high. The

blooms measure 7 inches across, 5 inches deep, perfectly solid in build; the florets are strap shaped, and have a semi-weeping character; the colour is a peculiar mixture of chestnut, bronze, and yellow, the reverse is pale gold. This year several American varieties promise well, Puritan, a pure white incurved Japanese, being worthy of especial notice. So is Sokoto, a new style of yellow. M. Bernard, a dwarf growing variety, has amaranth surface florets, having a silvery reverse. Middle Louise Leroy has the same style of flower as Avalanche in its formation, but having the faintest touch of blush pink on a white ground. Many other new varieties, both named and otherwise, are under trial, including several English raised sports from incurved varieties which need more time to determine their quality. All sections have an equal chance, one not being neglected at the expense of the others. Mr. Molyneux has an especial fancy for single varieties and Pompons, of which there is a capital collection now commencing to unfold their blooms. Bush grown plants covered with bloom of Lady Selborne evidently find favour. The plants are arranged in the usual "bank" style, so that a capital view can be obtained of the blooms all through.

I noticed the extreme dwarfness of the plants generally, plenty of the Queen type not being more than 4 to 5 feet high, the Tecks 3 to 4 feet high; the foliage is of that bronze hue generally noticeable in the Swanmore plants, while due regard is paid to the maturation of the wood, in which Mr. Molyneux is a stern believer. As showing the manner in which such varieties as Avalanche, for instance, is tested here, I noticed as many as forty blooms of this variety alone in one long row, and being arranged thinly among the Pompons the purity of this variety was much enhanced by its contrast with the deep green leaves of the small flowered varieties. The blooms were large and solid, but early. Edwin Molyneux is excellent; Sunflower is one of the best yellow varieties in existence, the drooping habit of its florets giving it a charming appearance; M. Astorg, Middle Lacroix and F. Marrouch are good; Thomas Stephenson, a sport from Criterion, was considered not to be distinct by the National Society's Committee from that variety, but is here totally different, being orange red. Violet Tomlin and Miss M. A. Haggas are developing blooms quite in keeping with the published descriptions of these grand additions to the incurved section. It is such varieties as these which have well formed blooms that add so much to the quality of a collection. In time it will not be necessary for cultivators to retain many sorts at present in favour, which are either rough or flat. Several new singles are under trial. These, as well as the Pompons, are being grown in two ways, some for producing specimen blooms, and others in quantity, which will prove the adaptability of these sections for producing bloom in both ways. Effie is a large flowering variety with long drooping florets of a peculiar mixture of chestnut and claret, the disc being pure yellow. Many other varieties were promising, but not at present far enough out to determine their quality. Older varieties, such as the Queen family, Princess of Wales, and Princess of Teck, Lady Hardinge, &c., promise good blooms later on.—VISITOR.

EARLY CHRYSANTHEMUMS.

THIS season has been one of great advance in many ways for the early flowering Chrysanthemums, although as far as regards the weather it has not been so favourable as some. The spring was good, we did not have so many or such late frosts as in other years, but August was unusually cold, not having the ripening influence so important to it. With all the progress that has been made, Mr. Wilks, the Secretary of the Royal Horticultural Society, truly says they are not nearly so well and generally known and valued as they should be.

The first striking event of the year was at the Rose Show, July 6th, at the Crystal Palace, when on entering the exhibition tent a row of Chrysanthemums in full bloom met the view. These were all of the Desgrange family, and consisted of forty-three fine plants, not with two or three flowers on a plant, but mostly bearing about a dozen good blooms, forming with other decorative plants a fine back row to the tables of Roses. They were exhibited and grown by Mr. W. E. Cass, Church Road, Norwood. Now it has been said that Chrysanthemums are not wanted at this time of the year, but I can truly say that there was no feature of that Show so striking or beautiful as this row of Chrysanthemums, and as a lady behind me remarked they looked better than the Roses. The day was very hot, and the Show being held in a tent with insufficient ventilation many of the Roses looked wilted and parched, but these plants and flowers seemed in their full beauty. It has been urged that they were of no use, but it should be remembered that they were not grown merely for exhibition but in the regular way of trade, were used after the show for furnishing purposes, and finally the flowers were cut and sold. Tolerably fair use for one set of plants being a sufficient reply to those who said they were no use, besides showing what can be done at so early a date as the beginning of July.

As regards the other Shows, the Dahlia Show at the Crystal Palace on September 6th and 7th was the place of struggle, for Messrs. Laing & Sons of Forest Hill, who, for the first time came in with a very large group, taking first prize, Messrs. Davis & Jones of Camberwell were second, and myself third. I think there should be some restriction in these exhibits. The schedule says, eighteen plants, three of a sort, six kinds, in 24-size pots; but this has hardly ever been adhered to. We have always tried to exhibit plants fulfilling the terms of the rule, but doing much more. In this case Messrs. Laing's group was nearly twice the size of Messrs. Davis & Jones's, so that, though the latter was very good, it had not the size to attract the attention of the Judges. What is

wanted to make the competition fairer is a restriction to the number of pots and sticks in them, say not more than forty or sixty pots with not more than three sticks in each, for if the sticks are not restricted as well as the pots we should have those flat monsters so common at the shows of the late sorts. Not less than six sorts would give latitude enough for show and the exhibition of new sorts. The latter at this Show were Madame la Comtesse Foucher de Careil, which obtained a certificate, and Grace Attick. I will not say more here about the first of these, as my own plants did not come early enough to form a fair estimate of them. I was able to show for the first time Golden Shah, Duchess of Fife, White Lady, Goldsmith, and Mr. Selly. Of the new sorts more further on.

At the Show at the Aquarium, Westminster, on September 11th and 12th, there was nothing so striking as last year. The groups were not so good as at the Crystal Palace. Messrs. Laing took first prize. Mr. J. R. Chard, Brunswick Nursery, Stoke Newington, London, was second. Mr. Stevens of Putney took third, and in his exhibit was a large lot of the new bronze sport of *Précocité* called Maud Pitcher. The only other remarkable exhibit I noticed were the blooms of Madame Desgrange exhibited by Mr. J. Blackburn, gardener to J. Scott, jun., Esq. of Elmstead Grange, Chislehurst, Kent. The petals of these flowers were so thick and stout that they looked like pieces of white kid, and were about the best I ever saw. Of course he had first prize.

The next notable incident of the season was the legal decision with regard to the claim to the name of the sport Mrs. Hawkins, which has already been referred to in this Journal. The first season the yellow sport of Madame Desgrange was made known I discovered about five other instances, and had five different names been given what confusion would have ensued. With regard to this new Mrs. Hawkins I may say that I have grown half a dozen plants, and the blooms were all darker than the old yellow one, *G. Wermig*, and this latter will be useless, for it is not nearly so good a yellow as the new one. So the three strains stand—Madame Desgrange, white; Mrs. Burrell, primrose; and Mrs. Hawkins, yellow, for I think no one will grow the old one if he can get the new.

The new sorts of this season are good and show a great advance. The first is the Golden Shah, a seedling of last year, from seed grown by me here the season before, and raised at Mr. Ware, Hale Farm Nurseries, Tottenham, London. It is the finest early yellow Pompon yet raised. It is early, thus a plant inserted as a cutting April 25th was in full bloom August 25th. Another plant from a cutting inserted May 4th was in full flower September 4th, eighteen weeks and three days. It grows from 18 inches to 2 feet high, is of slender habit with sparse foliage, forms an elegant plant, and flowers freely up to the middle and end of October by being struck late. The colour is a very deep bright yellow, and the flowers are $2\frac{1}{2}$ inches across, each borne on a fairly long stalk, making sprays for cutting of a most desirable form, as well as adding much to the gracefulness of the plant's appearance.

Duchess of Fife is another from the same batch of seed grown and raised as the above. It is a beautiful white Pompon. The flowers very much resemble Madame Marthe in the late ones, but it is early and dwarf, being only 13 inches high, a stout bushy plant. The flowers are $2\frac{1}{4}$ inches across, nearly globes, with short thick slightly incurved petals. It comes to perfection in a very short time, for a cutting inserted April 6th was in full bloom August 25th, and another inserted April 30th was in bloom September 4th. If I mistake not this will make a very popular small pot plant. It does well in a 48 or 32-size pot, and of course wants no stick. It is a real gem.

Mr. Selly is another dwarf seedling from my own seed grown here. It is a bluish white Pompon, very dwarf, a profuse bloomer, with the flowers all at the same level. A cutting put in on the 2nd of March was in full bloom on September 6th. It is a robust sort, only 21 inches high, with blooms $1\frac{1}{2}$ to 2 inches across, very flat in form.

Martimas, a new sort of French origin, of most robust habit. An excellent grower, and should it ever sport white will probably be one of the most generally grown for cut flower purposes, as it seems to grow more flowers than almost if not quite any other sort, and they come out nearly all at the same time, enabling the plants to be cleared at one cutting. It grows 3 feet high on stout wood, bearing flowers in masses of a pink colour $2\frac{1}{2}$ to 3 inches across, which are reflexed, and was in full bloom September 26th. It is a really useful sort either for decoration or cut flowers.

Capricine is a new French orange red Japanese sort, which blooms in October. It is very stout, requires no sticks, grows 30 inches high, with flowers 3 to $3\frac{1}{2}$ inches across, which come out at different levels, so that all can expand without disbudding.

October Beauty, imported from the United States, a useful outdoor sort, grows 28 inches high, stout enough to do without sticks, an excellent grower. Flowers pink mauve reflexed, 3 inches across.

Miss Lily Stevens is a beautiful little white Pompon with flowers over an inch across, the plant growing 2 feet high. Where a neat and unique small white flower is wanted this is one to fulfil the requirement. Blooms at the end of September.

William Cobbett is a salmon coloured Japanese. Good variety, 3 to 4 feet high, flowers 3 to $3\frac{1}{2}$ inches across, blooms in October.

In the French new ones sent over this spring as early we have been sadly deceived. I had fifteen of them, and up to this, 11th of October, only one has opened a flower—i.e., Madame la Comtesse Foucher de Careil they call a brilliant orange. It is a dwarf Japanese, rather a brighter colour than Capricine. It grows about 30 inches high, and the

flowers seem to grow about 2 to 3 inches across. It has obtained a certificate, but I should be sorry to pronounce a judgment on it till next season, as this has not been a good one here.

Grace Attick has proved itself to be the earliest of all Chrysanthemums, coming into bloom by the 1st of May, just a month earlier than our earliest one before—viz., Nanum. It has gained a certificate, as well it may, for it is a most exceptional plant, not only in its earliness but in its profuse and long continued flowering.

This season is marked by an increased appreciation of *O. J. Quinatus* as a producer of cut flowers, in which it has no rival for Japanese mauve blooms. It is an immense bearer of October flowers. It is a good after dark colour.

A Conference of the National Chrysanthemum Society on early flowering sorts was held at the Aquarium, Westminster, on the first day of the early Show, when papers were read by Mr. J. Doughty and myself to a well-attended meeting of appreciative members, and a very useful discussion followed.—W. PIERCY, 89, Beadnell Road, Forest Hill, London, S.E.

IPSWICH SHOW.

WE are requested to state that the Ipswich Chrysanthemum Show will take place on Tuesday and Wednesday, the 5th and 6th of November, instead of the 7th and 8th, and schedules can be obtained from the Hon. Secretary, the Rev. Hugh Berners, Harkstead Rectory, Ipswich.

RIPE GRAPES IN MARCH.

I AM pleased that my friend and late pupil, Mr. W. Palmer, has been so successful in the production of Grapes early in the season. My note is not intended as a criticism on what he has written on pages 306 and 307, but to congratulate him for stating clearly his practice for the guidance of others.

With regard to the eradication of red spider I observe that Mr. Palmer's recommendation to apply sulphur "to the pipes" is misprinted "to the roots," and the correction given was necessary to prevent any misapprehension arising on the subject. Red spider will in some cases disappear almost at once after the border has been thoroughly soaked with water, but this does not appear to be effective when the spider has been encouraged by other causes than dryness. I have tried many means, but taking the matter generally I have found nothing more effective than sponging the under side of the foliage directly the pest appears with sulphur and water in which a little softsoap has been dissolved. We invariably use a 3-inch potful in 3 gallons of water, and half an ounce of softsoap. This is the process when Grapes are hanging on the Vines. If they have been cleared off the Vines are thoroughly syringed with the same solution. The sulphur is allowed to remain on the Vines three or four days. The weather must be bright, after which the Vines are thoroughly washed with clean water. This is the readiest method I have been able to discover of destroying red spider either on plants that will bear full sunshine, Vines, Peaches, or Roses.

I do not believe in having the roots of Vines in a dry medium at any time. I have long been of opinion that considerable harm is often done by acting contrary to Nature in this respect. Vines, Peaches, Roses, and many other plants under glass during the period of rest are often too dry. The opposite is the case outside, and therefore I commend that part of the practice advocated by Mr. Palmer. The reason, however, for the early watering of the border to "induce root action before the Vines commence growing" is to me wide of the mark. Vine roots I am aware can be retained throughout the resting period in a perfectly fresh practically growing condition, but these are generally strong quill-like roots that eventually die back, and are much longer before they start again into growth than small fibres that have ripened thoroughly by the time the Vines are pruned. These fat roots can be induced to grow long before top growth is visible. This is brought about only by subjecting the roots to a higher temperature than that provided for the canes.

It is an open question whether root activity preceding growth is an advantage or the reverse to Vines. My experience has led me to the conclusion that it is unfavourable. It is an established fact that the Vine makes a considerable growth before its roots are called upon to furnish supplies. This being the case, root action preceding growth is not required, and only tends to upset, at least for the time being, the natural course the Vine would otherwise follow. It is simply reversing the natural order of things.

I can well understand the Vines breaking in the irregular manner they appear to have done. Hard forcing in nearly all cases induces the most unripened shoots to first break into growth. I have invariably found that Vines subject to uphill work rarely show fruit freely from the eyes to which they have been pruned. It can scarcely be expected, for they enjoy, comparatively speaking, a limited season of rest. A complete season of rest, however limited it may be, is essential to the health and vigour of the Vines. Very often when they are forced very early they have not completed the one season's work before they are forced again into growth. The system is an exhaustive one, and I should hesitate before subjecting a permanent vinery in good condition to such early forcing. My main reason is because such early forcing is unnecessary. Late Grapes can be had in excellent condition throughout March, April, and May, and I have kept them good until June. With the varieties Alicante, Lady Downe's, and Gros Colman, I fail to see why Vines need be forced to produce ripe Grapes before the first week in May or the middle of the month at the earliest.

I am aware that circumstances alter cases materially, and one is often obliged to practise systems that are not good for the well being of the Vines in order to attain certain results. Mr. Palmer's practice and the results he has attained are highly commendable, whatever may be the conditions that induce him to subject his Vines to such early forcing. —WM. BARDNEY.

ROYAL HORTICULTURAL SOCIETY.

OCTOBER 22ND.

THE space available for exhibits was fully occupied on Tuesday last at the above Society's Fruit, Floral, and Orchid Committees' meeting in the Drill Hall, James' Street, Westminster. At 3 P.M. Mr. W. Wildsmith delivered an instructive lecture on Pears and their culture, which kept a good audience together until nearly 4 P.M.

At the conclusion of the ordinary business of the Floral Committee the Chairman announced that the Council wished to ascertain the opinion of the Committee with respect to the alteration of the hour of meeting. Some had found 11 A.M. too early, especially when a distance had to be travelled, and it was thought that twelve o'clock would be more suitable to the majority. Several opinions were expressed by members, some in favour of the alteration and others against: some proposing 1 P.M. as a better time. As, however, all the members of the Committee were not present, it was decided that they should be communicated with by post. The members of the Orchid Committee had already been written to upon this subject, and the majority were in favour of 11 A.M. as the hour of meeting. It was also announced that the Council had decided to hold a Fern and Carnation Congress at Chiswick in July, 1890, which would probably be the only meeting of the kind held there next year.

FRUIT COMMITTEE.—Present—T. Francis Rivers, Esq., in the chair, and Messrs. W. Warren, W. Wildsmith, J. Burnett, W. Denning, R. D. Blackmore, G. Bunyard, Philip Crowley, T. J. Saltmarsh, G. T. Miles, W. Bates, G. Wythes, W. Balderson, J. Hudson, and J. Cheal.

Messrs. G. Bunyard & Co., Maidstone, exhibited some handsome specimens of Bismarck Apple, for which a cultural commendation was awarded, and some interesting particulars were furnished, for which we hope to find space in another issue. Messrs. Rothschild, Gunnersbury House, Acton (gardener, Mr. J. Hudson), was awarded a silver medal for a collection comprising twenty-four varieties of Apples and twenty-seven of Pears, all in admirable condition. Lord Suffield, Gunton Park, Norwich (gardener, Mr. Allen), also had a fine collection of dessert Pears, including some uncommonly good specimens (silver medal). From Messrs. W. Gaymer & Son, Attleborough, Norfolk, came a large collection of cider Apples, and a silver medal was awarded; a number of dishes of good Apples also coming from the R.H.S. gardens at Chiswick. Mr. T. Laxton, Bedford, showed specimens of his seedling Pears The Berkeley and Laxton's Bergamot. Mr. T. Myles, The Gardens, Appley Towers, Ryde, exhibited three seedling Grapes from a cross between Alicante and Gros Colman, two of which partook largely of the characters of the two parents respectively; the other was nearly intermediate, the berries roundish oval, richly flavoured, and bearing a good bloom; for this a first-class certificate was awarded, and it will probably be found a useful addition to the list of late Grapes. It was named Appley Towers Seedling.

Mr. W. Bates, Poulett Lodge Garden, Twickenham, was awarded a cultural commendation for three handsome Pine Apples, two of Smooth Cayenne, 6 lbs. each, and one of Prince Albert, 4 lbs., even, well-proportioned, and capitally grown fruits.

FLORAL COMMITTEE.—Present—J. Fraser, Esq., in the chair; and Messrs. B. Wynne, R. Dean, H. Cannell, W. Holmes, Lewis Castle, T. Baines, C. Noble, C. T. Druery, Shirley Hibberd, and G. Paul.

Messrs. J. Veitch & Sons, Chelsea, exhibited a large and beautiful group of plants suitable for table decoration, which attracted much attention, and the Committee unanimously awarded a silver Banksian medal for it. The plants represented were as follows, all in a small state, and admirably fitted for the use for which they were intended. Those with variegated foliage are marked with an asterisk. *Dracenas angustata*, *angustifolia*, *Cooperi*, *terminalis*, *norwoodensis*, *Louisa*, *terminalis alba*, *Doucetti*, *Ernesti Frederici*, and *gracilis*; *Crotons elegantissimus*, *Countess*, *Johannis*, *angustifolius*, *Chelsoni*, and *volutus*; *Aralias Veitchi gracillima*, *Kerchoviana*, *Chabrieri*, and *elegantissima*, *leptophylla* and **monstrosa*; *Panax Victorie* and *fruticosum multifida*; *Carex viridis* and **variegata*; **Bambusa Fortunei variegata*, **Pandanus Veitchi*, **Ananassa sativa variegata*, *Asparagus plumosus nanus* and *tenuissimus*, *Tillandsia Zahni*, **zebrina*, **majus*, and **tessellata*, *Nidularium amazonica*, *Nepenthes Mastersiana*, **Fittonias Pearcei* and **argyrea*, **Ophiopogon spicatus*, **Acalypha musaicus*, **Begonias Arthur Malet* and **Louis Chrétien* (improved), **Gynerium argenteum variegatum*, **Eurya latifolia variegata*, *Anthericum latifolium*, and **albo-medio pictum*, *Cocos Weddelliana*, *Geonoma gracilis*, *Kentia gracilis*, *Thrinax elegans*, *Kentia Belmoreana*, *Areca Verschaffelti*, *Phoenix rpicola*, *So-anum Capsicastrum*, **Ficus Parcelli*, *Grevillea robusta*, **Aspidistra lurida variegata*, *Sarracenia Chelsoni*, *melanorhoda*, *Wrigleyana*, and *porphyro-neura*. Ferns.—*Pteris serrulata*, *cretica nobilis*, *hastata*, and *adiantifolia*; *Adiantums farleyense*, *cuneatum*, *cardioclæna*, *fulvum*, *setulosum*, and *macrophyllum*; *Nephrolepis Duffi*, *Doryopteris palmata*, *Polypodium aureum*, *Scolopendrium vulgare* and *Kelwayi*. Messrs. Veitch & Sons also had a neat tastefully arranged collection of Japanese Maple leaves (bronze medal), and specimens of greenhouse

Rhododendrons, including one which was said to be a cross between *Azalea indica Stella*, and one of the *javanicum* type (vote of thanks).

Messrs. J. Laing & Sons, Forest Hill, S.E., sent a collection of *Chrysanthemum* blooms, comprising some grand blooms of new varieties, but in several cases as there were only two blooms they could not receive an award or special recognition. *Stanstead White* was beautifully represented; *Condor*, with extremely broad florets, but rather loose blooms; *M. Bernard* was also fine. Mr. G. Stevens, Putney, showed blooms of *Chrysanthemums Gorgeous* (Japanese) and Japanese *Anemone Jeanne Marty*, light in colour; and *Nelson* (award of merit). Mr. H. B. May, Upper Edmonton had an interesting collection of berries (bronze medal). Messrs. H. Cannell & Sons, Swanley, had an extensive collection of *Chrysanthemum* blooms and plants of the neat double white *Tuberous Begonia Octavie* (vote of thanks.) Very notable were *Miss Gorton*, pink Japanese, *Nelson*, *Sunflower*, *L'Or du Japon*, *Amy Furze*, *Avalanche*, and *Madame Laing*, a moderate size Japanese of a deep purplish hue.

Mr. W. Wildsmith, Heckfield Gardens, sent a stand of *Chrysanthemum* blooms, comprising twelve good blooms of *Avalanche*, some of the finest we have seen, and perfectly pure (vote of thanks). Mr. G. Wythes, Syon House Gardens, Gunnersbury, sent a large plant of *Hymenocallis macrostephana* in flower (vote of thanks).

ORCHID COMMITTEE.—Present—H. J. Veitch, Esq., in the chair; Messrs. J. O'Brien, H. Ballantine, H. M. Pollett, J. Douglas, and E. Hill.

Sir T. Lawrence, Bart., M.P., sent a plant of *Cœlogyne speciosus*, having buff coloured broad sepals and very narrow recurving petals, the lip white at the tip, dark dull red in the centre and at the base (vote of thanks). Messrs. F. Sander & Co., St. Albans, sent a plant of *Oncidium hæmatochilum pictum*, the sepals and petals regularly mottled with reddish brown, the lip mauve with a crimson centre; also a plant of *Dendrobium Slatterianum* in the way of *D. bigibbum*, but with larger and darker flowers in racemes. From Mr. Gledstane, Manor House, Gunnersbury, Acton (gardener, Mr. Dennison), came a fine plant of *Dendrobium formosum giganteum*, bearing about thirty large flowers (cultural commendation). Mr. Tautz, Studley House, Shepherd's Bush (gardener, Mr. Cowley), sent several Orchids, including *Odontoglossum Ins'eayi splendens* and *splendens aureum*, also a very large variety of *O. grande*, for which an award of merit was granted, and a variety of the same species named *aureum* with pale flowers. The Duke of Marlborough, Blenheim Palace, Woodstock, showed a plant of *Cattleya aurea blenheimensis*, in which the sepals and petals were of a lighter colour than usual.

FIRST-CLASS CERTIFICATES.

Epidendrum scepterum (Sir T. Lawrence, Bart., M.P.).—A botanical certificate was awarded for this Orchid, which has small flowers with narrow sepals and petals, yellow spotted with dark crimson, the lip roundish, white spotted with crimson and deeper at the tip.

Pteris leptophylla princeps (H. B. May).—A graceful erect Fern with irregularly but finely divided fronds somewhat inclined to be crested at the tips.

Carex variegata (J. Veitch & Sons).—A very narrow-leaved graceful plant, the leaves having a central white stripe, and elegantly recurving.

AWARDS OF MERIT.

Chrysanthemum Eynsford White (Messrs. Cannell & Sons).—A beautiful white Japanese variety with recurving florets of fine substance, deep handsome flowers. It was thought by one member of the Committee to be much like *Avalanche*, but blooms of the latter variety exhibited at the same meeting were totally different in character.

Chrysanthemum William Neville (Messrs. Cannell & Sons).—A Japanese reflexed variety with blooms of moderate size, bronzy yellow, the florets flat and notched at the end.

Chrysanthemum M. Pa-chouke (Messrs. Cannell & Sons).—A Japanese Anemone with large handsome flowers, the guard florets broad and spreading, the centre dense and high, the colour a deep reddish purple.

Chrysanthemum Nelson (G. Stevens).—A fine Japanese Anemone with broad guard florets and a good centre, purplish crimson.

Chrysanthemum Stanstead Surprise (J. Laing & Sons).—A handsome Japanese variety with drooping florets slightly upcurving at the tips, deep crimson in young blooms, silvery on the under surface.

NATIONAL AURICULA AND NATIONAL CARNATION AND PICOIEE SOCIETIES.—SOUTHERN SECTION.

THE annual General Meeting of the members of these Societies took place in the room of the Horticultural Club, Hotel Windsor, on the 22nd inst., Mr. Shirley Hibberd in the chair. Among the members present were the Rev. H. H. D'Ombraim, T. E. Henwood (Treasurer), J. Douglas (Hon. Secretary), H. Turner, H. Cannell, J. Lakin, R. Dean, C. Phillips, W. L. Walker, J. J. Kew, M. Rowan, &c. The minutes of the last meeting having been read the business of the Auricula Society was first taken. In reference to the dates of the exhibitions it was reported that it was thought that a meeting of the Royal Horticultural Society would take place on April 22nd, and that the Council would offer the Auricula Society the same terms as last year.

A letter was read from Mr. William Holmes of Hackney offering, on behalf of the Royal Aquarium Company, liberal terms to have the Auricula and Carnation Exhibitions there in connection with Exhibitions it was proposed to arrange. It was further stated that the Council of the Royal Horticultural Society proposed holding a meeting at Chiswick

on July 22nd and 23rd, that there would be an Exhibition of Ferns and Carnations, and arrangements had been made for a trial of border Carnations on a large scale. It was therefore suggested the Exhibition of the Carnation Society should be held in connection with this meeting; it was thereupon resolved that the Auricula Show should be held in connection with the R.H.S.'s meeting on April 22nd, that Mr. William Holmes be thanked for his offer on behalf of the Royal Aquarium Company, that the Carnation Show take place at Chiswick on July 22nd, the Committee of the Society to co-operate with the Council of the R.H.S. in carrying out a Carnation Conference, and it was suggested that Mr. Martin Rowan should read a paper on the "Culture of Carnations in Towns," and Mr. Richard Dean one on "Border Carnations." The Treasurer, Mr. T. E. Henwood, then submitted a financial statement, showing there was a balance in hand in favour of the Auricula Society of £7 18s. 9d., and of the Carnation Society of £4 7s. 5d., the sum of £25 having been invested at the commencement of the year. Mr. J. Douglas submitted a report dealing with the Exhibitions of the past year, and bearing testimony to the prosperous condition of both Societies. Mr. Shirley Hibberd was re-elected President of the Auricula Society; Dr. Hogg, Dr. Masters, Messrs. J. T. D. Llewelyn, H. S. Leonard, and H. J. Veitch Vice-Presidents; Messrs. J. F. Kew and J. Lakin were added to the Committee; Dr. Hogg and Mr. H. J. Veitch re-elected Auditors; Mr. T. E. Henwood re-elected Hon. Treasurer; and Mr. J. Douglas Hon. Secretary. Mr. J. D. T. Llewelyn was re-elected President of the National Carnation Society; the names of Lady Wolverton, Lady West, and Miss Tufnell were added to the Patrons; Messrs. H. S. Leonard and H. J. Pearson were added to the Vice-Presidents; the Committee were re-elected; and also Mr. T. E. Henwood to the office of Hon. Treasurer; and Mr. J. Douglas to that of Hon. Secretary.

The schedules of prizes of last year were adopted for the coming season, and it was arranged the Judges should be appointed at a meeting of the Committee on March 11th. The rules which applied to both Societies being found somewhat inelastic, they were duly revised and brought into harmony with the practice of the Society. The meeting closed with votes of thanks to the Treasurer and Secretary, and to Mr. Shirley Hibberd for presiding.

REVIEW OF BOOK.

Manual of Orchidaceous Plants. Part V. Masdevallia, Pleurothallis, Cryptophoranthus, Restrepia, Arpophyllum and Platyclinis. James Veitch & Sons, Royal Exotic Nursery, 544, King's Road, Chelsea. 1889.

THE character of this excellent work on Orchids is being thoroughly well maintained, each successive part issued giving abundant proof of the care exercised in its production, and that the effort to render it a reliable work of reference is successful. In the part under notice which has just been published, the sub-tribe Pleurothallia of the Tribe Epidendrea is that dealt with, including the genera named above, but the chief space is necessarily devoted to Masdevallias. The part is indeed really a monograph of this genus, and as such it possesses special value, for something of the kind has long been needed. An elaborate monograph, with coloured plates of all the species, has been promised and talked about for a considerable time, but we have not yet seen it or heard that it has been published. Such a book would be a valuable production, but the cost would place it out of the reach of many Orchid amateurs. That from Messrs. Veitch, however, now to hand, supplies all that is required of descriptive, cultural, and historical information at a moderate expense to the purchaser. It is, therefore, an especially welcome addition to Orchid literature, and one that will prove useful to amateurs and gardeners alike, as several important cultural details are included. Briefly noting the genera described, the first is

PLEUROTHALLIS.

Although 350 species are known of this genus, very few are in cultivation, and Messrs. Veitch only include six species as worthy of particular mention—i.e., *P. Barberiana*, *P. insignis*, *P. leucopyramis*, *P. picta*, *P. punctulata*, and *P. Roezli*. The others were mostly small plants with insignificant flowers, though some of these are interesting structurally. *P. Barberiana* is a curious little Orchid, also known as *Masdevallia Culex*, which is given as a synonym in the body of the work, but at the end of the *Masdevallia* portion, under the head "Excluded Species," *M. Culex* is said to be now referred to *Pleurothallis macroblepharis*. *P. insignis* is one of the largest flowered species, *P. Leucopyramis* has numerous small white flowers, *P. picta* has bright yellow and red flowers, *P. punctulata* has yellow flowers spotted with red and purple, and *P. Roezli* has the most richly coloured flowers of any *Pleurothallis* yet discovered, "deep sanguineous purple."

CRYPTOPHORANTHUS.

This genus has been founded upon the peculiar *Masdevallia fenestrata* of the "Botanical Magazine" (t. 4164), which had been previously described as *Specklinia atropurpurea*, so that under its new generic title (founded by Rodriguez in 1881), *M. fenestrata* becomes *Cryptophoranthus atropurpureum*. This is a very interesting plant with regard to its form and fertilisation, the three sepals being united at their tips, only leaving two small openings at which insects can enter. Mr. Darwin called attention to this peculiarity, and in his work on the

fertilisation of Orchids he furnished a full description of the structure. *C. Dayanum* has larger flowers of similar shape, but yellow spotted with deep reddish purple.

RESTREPIA.

The charming little *R. antennifera* is the best known of this genus, its delicately marked flowers being regarded by all Orchid admirers as amongst the most exquisite of the family. *R. elegans* is another attractive species; *R. pandurata* is said to be equally pretty, and *R. xanthophthalma* is also recommended for a place with the others.

MASDEVALLIA.

Sixty-two pages are devoted to the *Masdevallias*. Twenty-six species and hybrids are described, and illustrations are furnished of the most distinct or important. Full descriptions of the essential characters of the genus are supplied, followed by an analysis of the botanical groups under which the species are classed. The geographical distribution is treated upon at some length, and "a cultural note," occupying a couple of pages, embodies all that is necessary to be studied. We cannot refer to all the *Masdevallias* described, but it may be worth mentioning that the now well-known *M. Shuttleworthi* is placed as a variety under *M. caudata*, together with *M. xanthocorys*, *M. Wallisi*, *M. Winniana*, *M. Roezli*, *M. Gorgona*, and *M. Backhouseana* are all in a similar way placed under *M. Chimera* as varieties. The familiar *M. Lindeni* is discarded and assumes the original title *M. coccinea*, under which are ranked the varieties *conchiflora* and the useful handsome *Harryana*, with numerous sub-varieties. An interesting matter is recorded with regard to *M. towarensis*, and though it is known to many cultivators, beginners in Orchid culture are apt to overlook it. We therefore reproduce the passage, premising that it assumes more importance now the species named is so much grown for its flowers.

"A morphological peculiarity in *Masdevallia towarensis*, and also in the allied species *M. Ehippium*, *M. infracta*, and *M. maculata*, that was omitted when drawing up the sub-sectional characters of the *Polyanthæ Masdevallias*, may properly be noticed here. The so-called peduncles or scapes of all these species are sharply three-angled, and the flowers are produced from their apex, the pedicels issuing from a membranous persistent sheath that is single in *M. Ehippium* and *M. infracta*, but double in *M. maculata* and *M. towarensis*. When the flowers fade the pedicels and ovaries wither and drop with them if infertile, which is usually the case, but the long trigonal part does not wither and drop like the flower scapes of most *Masdevallias*; it continues green and fresh, and if not removed from the plant more flowers are produced from the apex in the following year precisely in the same way as on the first occasion. The same occurrence has been observed in the third season, so that it may be assumed, in default of direct observation, that so long as the leaf, from the base of which the so-called scape springs, is in a condition to perform its functions, so long will the flowers be produced from the apex of these trigonal scapes on the return of the flowering season. This circumstance shows that there is a material difference between the slender terete scapes of those *Masdevallias* that perish when the flowers drop, and the more robust three-angled ones of the species in question that persist and produce flowers from their apex two, three, or more seasons in succession. The latter are, in fact, bi-, tri-, and even perennial leafless stems, and not scapes in the strict botanical meaning of the term, such as is implied in the foregoing descriptions. It is highly probable, too, that this peculiarity is not confined to the species named above, but in the absence of direct observation we are unable to specify any others by name."

The hybrid *Masdevallias* include *M. splendida* and its variety *Pariatorcana*, regarded as a natural cross between *M. Veitchiana* and *M. Barleana*, *M. caudata-Estradae*, *M. Chelsoni* (*amabilis* × *Veitchiana*), the first hybrid raised in Europe; *M. Courtauldiana*, *M. Ellisiana*, *M. Fraseri*, *M. Gairiana*, *M. Geleniana*, *M. glaphyrantha*, and *M. Hincksiana*. The remaining genera, *Arpophyllum* and *Platyclinis*, better known in gardens as *Dendrochilum*, have several pages devoted to them, and conclude one of the most interesting parts yet issued.

FRUIT FORCING.

VINES.—*Late Varieties*.—For long and good keeping, without any deterioration of quality, Lady Downe's is without a rival, the fruit keeping fresh and plump until May. It is also a certain cropper, and though not so imposing in appearance as some it forms compact bunches, which finish in less time and invariably better than the large-berried varieties. Mrs. Pince is an excellent keeper when well finished, but when not thoroughly ripened it is from shrivelling the most unsatisfactory of the thick-skinned Grapes. Grown well it has the advantage of flavour over any thick-skinned variety, but it requires more time and heat to finish it satisfactorily than Lady Downe's. We have it in three

houses started at different times—viz., January, February, and March, and singularly it does much the best in the structure started in February, the berries being as black as jet to the stalk, and the quality equal to Black Muscat. It is one of those varieties that is not always amenable to spur-pruning, being most satisfactory on the rod or extension system.

Mrs. Pince is not a robust grower, the joints of the wood being far apart, and growing quickly; the base leaves are comparatively small, and the buds correspond, being small and ill-fed, and the variety often fails to afford profitable crops on the short or spur-pruning system. Alicante, started in good time so as to finish by the middle of September, is capital in crop and appearance through size of bunch and finish. It has the advantage of finishing well where other varieties do very indifferently. Gros Colman is the noblest of Grapes in its season, and the most profitable to grow for a market supply. It is magnificent in appearance, the berries being splendid, the bunches compact, and it is an enormous cropper. The latter property is often taken advantage of to the injury of the crop in finish and the prejudice of ensuing crops. It requires more time than any other Grape, and should be started early, so as to have August and September to finish in, and being allowed to hang a few weeks to mature its somewhat earthy flavour when cut as soon as ripe passes off, and is even relished by invalids. Gros Guillaume is magnificent in bunch and berry, and requires a long time to colour and ripen it thoroughly. On account of its large bunches it is often overcropped, in which case it is the poorest of Grapes, as it is not even sweet, and is most unsatisfactory for keeping through the softness of its footstalks. Grown well Gros Guillaume is anything but coarse or inferior in flavour. It is not always satisfactory when closely pruned, and is best grown on the rod or extension system. Alnwick Seedling is an excellent Grape, finishing invariably well, and is as good in appearance as Alicante, with a better flavour. West's St. Peter's also always finishes satisfactorily, and though its berries and bunches may be too small for our modern ideas of a late Grape, it is otherwise of a quality which renders it an excellent and esteemed table variety.

Of white varieties Muscat of Alexandria is supreme when finished so as to hang in good condition into January. Its great enemy is spot. The air must be kept from becoming stagnant, a temperature of about 50° being necessary, and air must be given early on fine mornings, with warmth in the pipes to expel moisture and allow of the berries being warmed equally with the surrounding air, moisture being kept from condensing on the berries. There must not be anything like a leak in the roof, and moisture must be prevented arising from the border by covering it with dry material, than which nothing answers better than roughly cut, clean, and dry wheat straw. This treatment answers equally well for Madresfield Court, which as a companion Grape to Muscat of Alexandria is unequalled. It will keep well into the new year, but has the disadvantage of losing colour by hanging similar to Black Hamburgs, but unlike these does not shrivel. Of late white varieties Trebbiano is large in bunch and berry, and when thoroughly ripened good in flavour, but is rather impatient of damp, which usually attack the berries at the footstalk. Syrian well ripened is by no means despicable, and similar remarks applying to Calabrian Raisin.

Earliest Forced House.—Where late Grapes are not cultivated in quantity to maintain a supply to May, or thin-skinned varieties are required by April, preparations must be made for early forcing. The Vines having been pruned in September, the loose bark stripped off, the house may be cleansed, the border top-dressed, and the Vines dressed with a solution of softsoap, half a pound to a gallon of water, brought to the consistency of cream with flowers of sulphur, adding, if there have been any scale, half a gill of spirits of turpentine, the composition being equally effective against mealy bug. The whole being in readiness as advised in former calendars, cover the outside border with leaves and stable litter preparatory to applying fire heat. If there be the convenience of making up a bed of Oak or Beech leaves, with about a third of stable litter, inside the house it will greatly facilitate the Vines breaking and be more beneficial to them than fire heat alone; therefore have them in readiness for placing in the house early in next month.

Earliest Forced Pot Vines.—To produce ripe fruit in late March or early April the Vines are best grown in pots as stated in a former calendar, selecting early sorts, such as Buckland Sweetwater, Foster's Seedling, and White Frontignan in white Grapes; and in black, Black Hamburg, Mill Hill Hamburg, Royal Ascot, and Madresfield Court. They should now be in position preparatory to starting them early next month.

FLOWER GARDEN.

Refilling Flower Beds.—Frosts have been partial, and in some positions, notably those on high ground, the summer bedding plants still present a gay appearance. Those who intend refilling the beds with spring-flowering plants ought not longer to defer destroying the tender plants, in order that their successors may be transplanted and become re-established before bad weather is experienced. The sooner the beds are refilled after the soil has been disturbed the better, as should this be delayed till much rain has fallen it will be impossible to do the work properly. All kinds of plants used must be firmly fixed in their fresh quarters, or they will not take quickly to them, and subsequent frosts will still further loosen the ground about them. No greater mistake can be made than to interfere with the beds, either for the purpose of clearing or refilling them in wet weather, the wiser course being to defer the work till it can be done cleanly and properly.

Suitable Plants.—Where a goodly stock for refilling the beds has been well prepared beforehand it is possible to arrange these in such a manner as to create an effect in the spring even more showy and pleasing than any summer displays. Aubrietias, Iberises, Arabises, Daisies, Forget-me-nots, Polyanthus, Primroses, Wallflowers, Violas, and Saxifragas are all largely used for spring beds, and with these such showy annuals as *Collinsia bicolor*, *Gypsophila elegans*, *Limnanthes Douglasii*, *Myosotis dissitiflora*, *Nemophila insignis*, *Saponaria calabrica*, *Silene pendula* in variety, and Virginian Stocks. Masses of one colour with a suitable edging are usually most attractive, and for this reason it is unwise to go in for indiscriminate mixture, or to attempt to do too much with a limited stock of plants. For instance, single lines of Polyanthus are by no means showy, but if a good-sized bed is filled with them, and edged, say, with common Primroses, quite a fine display will be had in the spring, especially if the best strains of seed have been obtained. Masses of Wallflowers, *Myosotides*, *Silenes*, *Saponaria*, *Saxifragas granulata flore-pleno*, *pyramidalis*, and *umbrosa*; and Virginian Stock, edged with a neater growing yet showy kind of plant affording a suitable contrast, these including red and white Daisies, Violas (white, yellow, and blue), common Primroses, *Arabis*, *Aubrietias*, *Alyssum saxatile*, *Hepaticas*, and *Iberis sempervirens*, will, if the beds are well filled, be very beautiful next spring. Seeing that very few of the foregoing will increase in size all should be planted rather thickly, or so as to cover the ground without crowding.

Shrubs and Conifers.—These, with other hardy plants, are frequently used extensively with good effect in these winter and spring displays. In this case again mixtures are not, as a rule, the most effective. It is possible to arrange a well-assorted collection of dwarf hardy shrubs and Conifers in large beds, much after the style smaller beds are filled in the summer with carpeting plants. Panels of *Retinosporas ericoides*, *obtusata aurea nana*, *plumosa*, *plumosa argentea* and *aurea squarrosa*, and *Taxus baccata elegantissima*, with dividing lines of the more erect *Cupressus Lawsoniana* in variety, notably *C. Lawsoniana erecta viridis*, are very pleasing in appearance all through the winter and spring months. Good masses or broad bands of Hollies in variety, variegated *Aucubas*, *Boxes* in variety, *Kalmia latifolia*, *Mahonia aquifolia*, *Laurustinus*, *Osmanthus ilicifolium aureum* and *variegatum nanum*, *Euonymus japonicus* in variety, Golden and Silver Variegated Tree Ivy, dwarf *Rhododendrons*, and *Vinca elegantissima* also look well; and among more dwarf subjects must be mentioned the very showy *Ericas herbacea carnea*, *mediterranea alba* and *rubra*, and *vulgaris aurea*. Small well-formed specimens of some of the beautiful Conifers, and especially the *Retinosporas*, are very suitable for dotting among dwarf-flowering or fine-foliaged plants, and so also are *Yucca recurva* and *Iris foetidissima variegata*, large clumps of the latter dividing readily into neat pieces. All the foregoing can be bought in quantity from the principal nurserymen who prepare them specially for the purpose, and if taken good care of when the beds are cleared in May will be available for several seasons. If old plants of Golden Pyrethrum, Variegated Thyme, *Euonymus radicans variegata*, and *Stachys lanata* are saved when the flower beds are broken up, and the smaller well-coloured Beet selected from the kitchen garden crops are taken care of, each and all of these are suitable for edging the beds filled with the shrubs and Conifers above named.

Spring-flowering Bulbs are very beautiful, and flower earlier in the season than do the flowering plants and shrubs. Unfortunately the greater portion of them are of little service a second season, and those, therefore, who have preserved the bulbs that flowered last season will do well to plant these in mixed borders, or where they will not be disturbed for several years, a fresh stock being bought at once for affording a display next spring. Hyacinths, Narcissi, Tulips, Crocuses, Scillas, and Snowdrops are the bulbs most generally planted in beds, and the sooner they are got in the more strongly they will flower, it being of importance that all become thoroughly well rooted before the flower spikes are thrown up. By some mixtures of Hyacinths and Tulips are considered most pleasing, and others prefer to see masses of one or two colours only, the front lines or circles being planted with either Crocuses, Snowdrops, or Scillas. Single rows of the latter present a somewhat meagre appearance, and a band composed of about three lines is far more attractive, the bulbs being dibbled from 3 inches to 4 inches apart, and the same distance deep. Narcissi and Hyacinths may be disposed about 9 inches, and Tulips 5 inches apart, and 4 inches deep in each instance. If bulbs only are planted in beds the latter may be covered with neat sprays of Tree Ivy, Holly, Portugal Laurel, or *Aucuba*, arranged much as the beds might be filled with plants, and firmly fixed without injuring the bulbs. Failing this, the beds would present a more cheerful appearance during the winter if covered either with fresh ballast or cocoanut fibre. Bulbs are also effective when used in conjunction either with dwarf flowering plants or shrubs, in which case they need not be so thickly planted. The Narcissi being the tallest ought to be somewhat in the background or the centre of a bed, the Hyacinths coming next, and then Tulips.

Christmas Roses.—These are occasionally transplanted to the flower beds at this time of year, and if the coarsest and oldest leaves are removed prior to flowering they are fairly effective. This season they promise to be exceptionally floriferous, a showery summer suiting them well. They transplant to the beds and back to their summer quarters readily enough, but disturbed in this way they rarely flower well the following season, and two series of plants are therefore required, each being allowed a rest alternately.

PLANT HOUSES.

Lilium Harrisii.—These are ready for removing from the plunging material in which they were placed when first potted. If left too long the material used for covering the surface will become full of roots and be difficult to remove without injury. If the soil has not been watered a good soaking may now be given and the plants placed where a night temperature of 50° can be maintained. A light position is essential, admitting air daily when the weather is favourable. For the next few weeks the flower stems will grow rapidly and strongly if sufficient ventilation is provided to prevent their drawing up weakly. *Lilium candidum* removed from cold frames to the same temperature will quickly commence pushing up flower stems, but this *Lilium* must not be hurried in its early stages.

Lily of the Valley.—After these are potted or placed in boxes amongst leaf soil or cocoa-nut fibre refuse place them outside, where they can be kept moist. Expose the crowns, and after one good frost they may be introduced into the forcing house. After they have been frozen they advance rapidly and come into flower. Brisk heat is necessary for the early ones, and the crowns should be covered with a few inches depth of the material in which they are plunged.

The Forcing House.—Where quantities of forced flowers are required set apart a house or pit for the purpose. Select one if practicable where a slight hotbed can be formed. Good leaves are now plentiful for this purpose, and if these are mixed in a dry state with a small quantity of litter from the stable it will retain gentle heat for a long time. Rhododendrons, Ghent and Japanese Azaleas, Lilacs, Guelder Roses, Deutzias, and other similar plants are assisted wonderfully during the declining weeks of the year by the aid of gentle warmth at their roots. The genial moist heat that rises from fermenting material is much more suitable for exciting the plants than the dry heat derived from hot-water pipes. When hardy flowering shrubs have been plunged in a bed of this description no better position can be found for Tulips, Hyacinths, and Narcissi than to stand them on the surface of the bed amongst the other plants.

Hardy Flowering Shrubs.—Lift these in quantity and pot them from time to time as Chrysanthemum and other pots become vacant. Leave them outside until a sharp frost has cleared deciduous kinds of their foliage. It is not necessary to house plants of this nature; they are better outside until they are wanted. Plunge the pots to protect them from frost. *Spiraea japonica* should be lifted and potted; place them outside for a time afterwards.

Deutzia gracilis.—All the plants needed for forcing are established in pots, and will remain outside until the whole of their foliage has fallen. Our earliest plants are grown for a time inside, and therefore they are ready for introducing at once into the forcing house. Repot young plants that have been raised from cuttings and grown in outside borders. However strong and good they may be they are unsuitable for forcing. If forced before they are thoroughly established in their pots growth will be puny next year. If placed in 6 or 7-inch pots according to the size of the plants, and plunged outside until severe frosts set in, then pruned and plunged in cold frames and allowed to start into growth in this position in spring, they will be useful by the following autumn, and in the best condition for forcing. To keep a stock of plants in the best of health and condition it is not only wise to pot a few young plants annually but to partially reduce the bulbs of a few that display signs of declining vigour. The latter in other respects should be treated the same as young stock. One season's rest is ample to induce them to make strong clean growth from the base.

Hybrid Perpetual Roses.—Where these are wanted for flowering in pots to precede those grown outside or for next year's forcing, plants grown at home may be lifted at once. Place these in 7 or 8-inch pots according to their size. Ordinary trade plants lifted at the end of the month may be placed in the former. Straggling roots may be shortened, and also long growths, leaving them about 2 feet long. The pots should be clean and well drained, and the plants potted in a compost of good fibry loam, one-seventh of manure, one 6-inch potful of bone meal, and the same quantity of soot to each barrowful of loam. If the loam is heavy add sand, old mortar, charcoal, or anything similar that will keep it open and porous. If light add clay that has been reduced to powder by drying. After they are potted plunge them outside, covering the surface of the soil with the plunging material. During bright or dry weather syringe daily to keep the foliage fresh to induce the formation of roots.

they need not be separate. The fine quality when hives are properly managed does not decrease the quantity, unless when full-sized sheets of foundation have not been used, which I also commend. When full these are used in supers it renders the honeycomb unpalatable and unfit for the table of delicacies, so do the previous year's built combs. Notwithstanding all that has been written upon the production of comb honey, much of it reaches the market as a third class article.

Owing to circumstances over which I had no control my hives were fewer in number than previously, and even the third of that fewer number were all I had at the moors. Should health permit the same will not occur again. Owing to this many of my regular customers have been unserved. Their disappointment was great, but not more than my regret. Not only did I fail to supply the regular demand, but many new customers came; the sole cause of this being people have learned that great care is taken that nothing comes into contact with our honey that the most fastidious would object to. A number of wealthy people have asked for honey from this year, and make no secret of the cause of their visit. The following is the expression of one lady:—"We like honey, and would use much of it when we have the assurance that it is cleanly handled. As to comb honey, we cannot think of using that openly exposed in shop windows." Several years ago I drew the attention of your readers to the above objectionable practice. Honey exposed to the atmosphere is liable to become a source of danger to those who eat it, as it undoubtedly absorbs noxious gases and odours.

Then as regards drained honey, there are very few who have the proper appliances for extracting thick honey, such as Heather honey is, and the process of extracting without them is too well known to encourage the desirable consumpt of honey. Reams of paper and tons of honeycomb have been blackened by the departure from common sense management to that of employing queen-excluders and honey boards as they are termed.

Owing to my inability to supply all the demands from my own I made an effort to secure 20 lbs. of first-class honeycomb wanted for a special purpose. I overhauled some 600 lbs. in all of two apiaries, and failed to secure even 10 lbs. first class. The largest owner of about 500 lbs. has seen his error, and a reconstruction of his hives has already been made, so that neither queen-excluder zinc, open crowns, nor previously made comb will ever be employed by him again.

THE STEWARTON HIVE.

The Stewarton hive and its properties have so often been touched upon that I need not repeat them, but add that this year has especially suited them. They have yielded more honey, and, singular to say, are the only ones within my knowledge that have given fully completed supers of matchless purity. It has been often contended that sections cannot be wrought upon them. This is a fallacy. One of the simplest modes is to have the supers of the proper depth (not square ones) for sections, so that they clear the top of the hive a quarter of an inch, and of one width throughout, except the bottom rail, which should not be more than five-eighths of an inch broad. Fasten the sections to the top bar with fine wire nails half an inch long. The outer bevelled bars may be allowed to stand as they are, serving to supply customers able and willing to purchase more than a pound at a time.

Strange to say that "Scot" has been working his sections in this manner unknown to me. After the full sections are removed a pair of cutting pincers or plyers applied to the projecting nail points removes them easily. At this time our strongest hives in our narrow square hives—and some of them are extra strong—have a cold feel at the corners, whereas in equally strong Stewartons there is no perceptible difference, and it is simply this equalisation of temperature that is so favourable for making the Stewarton hive the best honey producer. The heat on the crown of any of our hives is the index which tells us the condition of our hives and what to do at the proper time, and the hive that has not enough proper material to destroy this is improperly covered.

NOTES ON BEES.

MAKING COMPARISONS.

IN order to give bee-keepers every opportunity of getting their bee-keeping appliances in perfect order for next season I cannot do better than describe what I have witnessed in comb honey during the past week or two. It is well known that I advocate superior quality to that of quantity, but at the same time have shown that

STORING OF HONEY.

Bees perform this work in a manner so perfect that we have only to look into Nature's larder to see it in perfection, the honey being stored and sealed in hermetically sealed cells, so that the external air will have no influence on it whatever. The honey overhanging the cluster of bees is never allowed in a normally strong hive for long, but is either first consumed by the bees or is immediately removed to a warmer place in the hive, and this is one of the reasons that octagon or round supers are, as a rule, better finished than square ones.

SCREW CAPS.

Jars having screw caps are, as a rule, greater favourites with bee-keepers, especially competing ones, but they are not as made the best for storing honey in. The screw is never so close as to exclude air nor prevent the escape of honey, and honey stored in them does not retain its natural consistency, but gets gradually thinner the longer it is kept. The same may be said of preserves. We have some Morello Cherry jam in them, as well as in tie-overs, and in common jelly cans. In every case where the screw caps are used the jam is fermented, while that in the tie-overs covered with good vegetable parchment is in a good state of preservation. Honey sometimes stands a good deal of ill treatment, but it is always advisable to do what is right for its preservation until it is eaten, although the plan is not popular.

COMPARISONS AND RESULTS.

Before closing this chapter it may not be out of place to give both sides of the success and non-success of an Arran bee-keeper. At one time he was a successful bee-keeper on the Stewarton principle, but became a convert to that hive that its inventor said of it, "The hive that was suitable for one locality might not be that for another," a saying not in accordance with facts, nor within our experience. This bee-keeper has somewhere about fifty of these combination hives, has not a single pound of honeycomb, while those having Stewartons almost side by side have a large surplus. I have always maintained that there are different systems which should be pursued according to season and locality, but the proper hive is one that can be easily adapted to both under any circumstances, and the hive that cannot be controlled to suit these is not the hive, and hives sent out without the vendors being able to give proper instructions is a dead score against them.

BLOW'S PATENT GROOVED SECTION.

A correspondent has sent me a section grooved for foundation marked as above with several queries, one of which, "Is it new?" It is not new; besides, the groove for foundation was my own contrivance in 1862, and I know of others that had their frames grooved all round as early as 1874; besides, when I made sections they were always grooved, and that from the first. I know nothing of the patent laws, but I do not think that they will prevent anyone in the face of the above facts from making, using, or selling grooved sections without being mulcted in any tax whatever, as the plan is not new, which I am prepared to prove.—A LANARKSHIRE BEE-KEEPER.

MR. ALFRED NEIGHBOUR.

THE "British Bee Journal" has recently published a portrait of the above named well-known bee-keeper, accompanied by the following biographical remarks:—

Mr. Neighbour was born in High Holborn, London, on the 24th of October, 1825. He is the son of the late Mr. George Neighbour, and a member of the firm of George Neighbour & Sons. His father established the business in Holborn about the year 1814; and in 1824 Mr. Thomas Nutt of Spalding, Lincolnshire, inventor of the collateral and other hives, offered him the agency for the sale of these appliances. In 1827 Mr. Nutt published the first edition of his work entitled, "Humanity to Bees," which ran into a seventh edition. Mr. Nutt was in the habit of periodically visiting his patrons who resided in the neighbourhood of London; and Mr. Alfred Neighbour frequently accompanied him in these excursions, and witnessed his fearless manner in manipulating with bees, and thus in very early life acquired a taste for apianian pursuits. For many years a public apiary was kept up by Mr. Neighbour in the Zoological

Gardens, Regent's Park. The hives were originally Nutt's; at a later period the unicom and other transparent hives were substituted, which proved to be more attractive to visitors. These excited considerable interest, and were by no means the least valued objects in the Gardens. The Royal princes and princesses were accustomed when children to pay frequent early morning visits to the Gardens, and the bee-house came in for a share of their attention. On one of these occasions Mr. Neighbour was fortunate to be at the apiary, and had the honour of pointing out to them the queen bee, and explaining the mode of working the hives. This apiary was pulled down to make room for the large monkey house, and the Council of the Society have not seen their way to erect another bee-hive house in its place.

The Great Exhibition of 1851 offered the first opportunity for the competitive display of hives. Side by side with the late Mr. John Milton of No. 10, Marylebone Street, Wimpole Street, Messrs. Neighbour exhibited living bees in glass hives, and a collection of bee furniture. It was at this Exhibition that a French exhibitor, M. Debeauvoys, was awarded the first prize for his vertical frame hive. This was the earliest frame hive brought to this country, excepting Huber's leaf hive, which differs in construction from that technically known as a frame hive. The moveable comb hives then constructed in England were those of Dr. Bevan, Mr. Golding, and Mr. H. Taylor, which had top bars only. The combs had to be severed from the sides of the hives whenever required to be drawn out and inspected. The success attending the Great Exhibition induced other exhibitions to follow, and at Dublin, Edinburgh, and at Paris, the firm of Neighbour & Sons received many prizes for their collection of miscellaneous appliances.

Mr. Neighbour was very closely acquainted with Mr. Henry Taylor of Highgate, author of the "Bee-keeper's Manual," who frequently was a guest of Mr. George Neighbour at Dorking, whither the latter gentleman had retired when he was released from business; and in consequence of this intimacy Mr. Neighbour had many opportunities of improving his knowledge of apiculture.

In consequence of an offer from Mr. Hermann in Switzerland to send over a Ligurian queen bee to be placed at the head of an English stock, Mr. Woodbury was induced to avail himself of the offer, and at the same time Mr. Taylor persuaded Mr. Neighbour to make application for a queen; the two queens arrived simultaneously. Mr. Woodbury was successful in joining his queen to an English stock. This was the commencement of a new era in bee-keeping, and with the introduction of the Ligurians to this country there sprang up an acquaintance between Mr. Woodbury and Mr. Neighbour which continued till the death of the former in July, 1870, at his residence, Mount Radford, Exeter.

Soon after the introduction of the Ligurian bee, Mr. Langstroth, the American apiarian, published his work, "The Hive and Honey Bee," which described his invention of hives on the bar-frame system, and at the same time bar-frames were also brought to notice in Germany by Baron von Berlepsch, who made improvements on Dr. Dzierzon's method. Mr. Woodbury was not slow in estimating the value of this invention, and, in adapting the combs of his bar hives to it, he constructed what he termed "a compound frame," which consisted of a frame with open top and shoulders on each side of which the bar rested, whilst the comb as taken from the hive was suspended vertically within the frame. Messrs. Neighbour, who were the first vendors of Woodbury hives, resorted to fixed frames as originally planned, and which have been in use ever since. The second London International Exhibition was held at South Kensington in 1862, at which Messrs. Neighbour exhibited living bees and hives. The space awarded was in the Agricultural Annexe, a location not nearly as good as that in the first Exhibition of 1851.

Mr. Neighbour in recent years has been much engaged, with the aid of Mr. Duncan Keir of Scotland, who was introduced to Mr. Neighbour by "The Renfrewshire Bee-keeper" (J. M. McPhedran, Esq.), from whom also many valuable hints were given to assist the enterprise, in packing and forwarding humble bees to New Zealand during winter, and whilst in a torpid state. These bees were much needed in the colony for the fructification of the Red Clover, the blossom of which is inaccessible to the ordinary honey bee. The importation of Cyprian, Syrian, and Holy Land bees has also claimed much of Mr. Neighbour's attention. Mr. Frank Benton, who, as is well known, has made a temporary home in Cyprus and Syria for the purpose of procuring queens from native sources, was accustomed to forward small colonies of these bees to Mr. Neighbour to be refreshed at his apiary, and re-shipped to Mr. D. A. Jones in Canada. Some of the earlier consignments were very satisfactory, but, owing to a change in the packing the business became so discouraging (but a few queens survived) that it was discontinued by him. Mr. Neighbour was the first to introduce the Carniolan bees into this country. He continues to cultivate and recommend them for their docile qualities. At the Swiss or German department of the Exhibition Mr. Neighbour purchased the impressed metal plates for making wax foundation. Many castings were made from the original and disseminated to various parties. From the foregoing it will be seen that Mr. Neighbour has enjoyed unusual opportunities of becoming acquainted with the leading apianian celebrities of the day; among others the Rev. William Charles Cotton, M.A., rector of Frodsham, Cheshire, and Dr. Coster of Hanwell.

In 1880 Mr. Neighbour attended, in company with Mr. S. Stutterd, the translator of Dr. Dzierzon's book, the German meeting of bee-masters at Cologne, at which his firm were exhibitors, and received from the hands of the Burgomaster at the public distribution of prizes the State silver medal. He had the pleasure of being introduced to most

of the leading bee-keepers attending the Congress, which included Dr. Dzierzon, Herr Vogel, the Baroness von Berlepsch, Dr. Pollman, and many others.

Reference has been made to Mr. Neighbour keeping bees at Dorking, but "foul brood" unfortunately broke out in his apiary there, and a convenient plot of ground offering at West End, Hampstead, he began afresh nearer London, which was so much more convenient for him. Over twelve years' residence at Hampstead was brought to a close in consequence of the ground being required for building purposes; so a place had to be sought removed from the liability of such disturbance. This was found at Buncfield, Hemel Hempstead, where his apiary at present is.

In the year 1852 Mr. Neighbour acquired premises at 149, Regent Street, possession of which he retained till very recently, when they were required for Government purposes. His business is now conducted at 127, High Holborn.

Mr. Neighbour is the author of a work on bees, entitled "The Apiary; or, Bees, Bee Hives, and Bee Culture," which has passed through three editions. He has a library containing perhaps the largest and best collection of books on the subject of bees and bee-culture of anyone in the kingdom, many of the works being of great age and very rare.

TRADE CATALOGUES RECEIVED.

W. & J. Birkenhead, Fern Nursery, Sale, Manchester, — *Lists of Ferns, and Selaginellas and Bulbs.*

G. Prince, 14, Market Street, Oxford. — *Catalogue of Roses.*

Dicksons & Co., 1, Waterloo Place, Edinburgh. — *List of Select Roses, 1889-1890.*

Wm. Cutbush & Sons, Highgate and Barnet. — *General Catalogue of Plants.*

Cooling & Sons, Bath, Somerset. — *Catalogue of Roses and Fruit Trees.*

P. J. Looymans & Son, Oudenbosch, Holland. — *List of Trees.*

All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Books (J. F. M.).—We do not know that any work is published on the subject you name. You could perhaps obtain the information by writing to Mr. Leonard Coates, Fruit Grower, &c., Napa, California. (*E. Hurton*).—The gold medal Fruit Essay is expected to be ready in November, and will be issued from this office, price 1s.; post free, 1s. 3d. (*J. E.*).—Mr. B. S. Williams' "Orchid Grower's Manual" will be found useful, also Mr. L. Castle's "Orchids: their Structure, History, and Culture," post free from this office, price 1s. 2½d. You are probably not aware that Thunias make and lose their growth annually. That is probably the case with your plant.

The National Chrysanthemum Society's Catalogue (T. K.).—The above catalogue can be had from this office post free 1s. 1d.

Onions (Constant Reader).—The varieties you mention are not red. As the other information you seek is of a local character, you can best obtain it by writing to Mr. H. Deverill, Banbury, Oxon.

Exhibiting Primulas (F. T.).—If there is no stipulation to the contrary in the schedule, you can stage either double or single Primulas, or both, choosing what you consider the most meritorious plants.

Storing Fruit (W. J.).—The conditions most conducive for the preservation of fruit are a dry atmosphere and a cool equable temperature with darkness. Light hastens decay; so does a close, warm, damp atmosphere, while over-dryness with heat induces shrivelling. It is well, then, to keep your fruit-room tolerably dark, cool, and airy. We would not be at the trouble, however, to barricade the windows to any inconvenient extent.

Dog's-tooth Violets and Ixias (E. J. N.).—They can both be grown in pots plunged just over the rims in cocoa-nut fibre refuse in cold frames, allowing them to remain there till the flowers commence expanding, then the plants may, if desired, be removed to a greenhouse. They require full exposure to the air during mild weather after growth appears, drawing off the sashes on all favourable occasions. The Temple Chrysanthemum Show is not open to the public on Sundays.

The Preservation of Fruit by Evaporation (H. C. W.).—If you consult the *Journal of Horticulture* of August 29th of the present year you will find an illustration of an appliance for this purpose that was tried at the Royal Agricultural Show at Windsor, and proved satisfactory. It was exhibited by Messrs. Y. C. Mayfarth & Co., Franfort-on-Maine, and awarded the first prize. We think there is a London agent, but this you can ascertain by writing to the proprietors of the apparatus at the address given.

Orchid Leaves Diseased (J. J. Lancashire).—The cause is probably an excess of moisture, and it frequently occurs in houses where too much fire heat is employed, with a corresponding amount of water and insufficient ventilation. The plants then become weakened and unhealthy, and are readily injured. The hardier the plants can be grown consistent with their safety, the more likely they are to escape such diseases. An unduly low temperature, and damp, stagnant atmosphere will induce a similar leaf disease.

Keeping Grapes (J. G.).—As the Grapes will not keep on the Vines you have nothing to lose by inserting the laterals bearing the bunches in bottles of water, fixed slantingly so that the berries hang clear, in a dry room having an equable temperature of about 45°. A degree or two less is not a matter of consequence, but sudden fluctuations of temperature are inimical. Very much also depends on the condition of the Grapes. Well ripened and with good skins we have frequently had Black Hamburgs in excellent condition at Christmas.

Norfolk Beefing Apple (A. T. H.).—You say for fifty years you have seen the name spelt "Biffin." So have we. The "Fruit Manual" says:—"This Apple is extensively cultivated in Norfolk, where, besides being applied to general purposes, the fruit is baked in ovens, and form the dried fruit met with among confectioners and fruiterers, called 'Norfolk Biffins.' The name of this Apple is sometimes written Beaufin, as if of French origin, but it is more correctly Beefing, with a good English ring, from the similarity the baked fruit presents to beef."

Scale on Rose Leaves (J. C.).—The leaves you have sent are infested with scale, which can be destroyed by the softsoap and petroleum mixture that has been so often recommended, and the method of preparation described, that it seems scarcely necessary to repeat it. Half a wineglassful of petroleum well mixed in a solution of nicotine soap or Gishurst compound will destroy the insects if applied towards evening with a syringe, but it is desirable to afford shade the day following if the sun is bright. We should not like to have so much scale in a vineyard of ours as you appear to have in yours. Printed instructions for preparing the insecticides named accompany them.

Plants for Rockery (R.).—*Alyssum maritimum*, *A. saxatile* compactum, *Arabis alba* variegata, *Arenaria purpurascens*, *Aster longifolius* formosus, *Aubrietia deltoidea* grandiflora, *Campanula garganica*, *Cheiranthus alpinus*, *Cistus laurifolius*, *Cytisus decumbens*, *Draba boeotica*, *Erica carnea* and var. *alba*, *Erysimum rupestre*, *Genista præcox*, *Iberis correaefolia*, *I. sempervirens* plena, *Lithospermum prostratum*, *Lotus corniculatus* plenus, *Phlox subulata* Nelsoni, *P. verna*, *Potentilla splendens*, *Saxifraga Burseriana*, *S. Camposi*, *S. Cotyledon pyramidalis*, *S. longifolia*, *Sedum spectabile*, *Silene maritima* plena, and *Zauschneria californica*. *Hypericum calycinum* and *H. olympicum* do well in somewhat shady dry places, also *Vinca major*, and var. *elegantissima*, *V. minor*, and var. *plena*. All the others require sunny positions.

Galvanised Wire for Walls (F. J. B.).—Galvanised wire answers well for fruit trees both outdoors and under glass. The wires for Peaches, Nectarines, and Apricots are usually 6 to 7 inches apart, or in every alternate course of bricks, but we find it better to have them corresponding to every course. As yours is a stone wall we should have the wires 6 inches apart. The nearer the wires are to the wall the better for the trees, but for convenience of tying they require to be ¼ to ½ inch. When there is a space between the wires and the wall greater than that named we find the growth of the trees is not so satisfactory, probably from their not being benefited to the same extent by its warmth, or it may be due to the current of air constantly taking place in the space between the trees and wall. No. 12 is the most suitable wire, that known as "specially prepared galvanised wire for walls" being the best kind to use.

Lapageria alba—Coleuses (W. W., Reading).—You would possibly do more harm than good if you were to materially disturb the roots of your *Lapageria* now. Turn it out of the pot carefully, pick away any inert soil with a pointed stick, so that the roots may be in contact with firm turfy peat that you may press firmly round them with a blunt stick. Perhaps the same sized pot will do, or one very slightly larger. Water must be given with judgment, avoiding the extremes of periodical over-dryness and saturation. The temperature is suitable, but the plant will be better on a close base than a latticework stage, especially if this is over hot-water pipes. *Coleuses* are stove plants, and if you cannot contrive to affix a case or frame over the heating medium

for insuring a temperature of about 60°, you cannot preserve the plants. If you can maintain a temperature of 65° now in a case, you can insert cuttings for rooting, and throw the old plants away.

Pear Tree not Blossoming—Greasing Tree Stems (*Perskore*).

—As the tree has evidently made good growth—indeed has probably grown too luxuriantly—we should dig it up carefully and transplant. By well undermining a good amount of soil can be removed with the roots. All those of a fibrous nature should be preserved, and the longer, which may be cut through with a spade or broken, should have the ends pared smooth with a knife. If you can procure some lime rubbish and wood ashes for mixing with the soil, do so, and press it firmly round the roots, and cover the surface with not very much decayed manure. We should transplant as soon as most of the leaves can be shaken or rubbed off. If the branches are crowded some of them may be cut out entirely, not shortening those which remain, and the tree should have the support of three stout stakes fixed triangularly, with padding between their tops and the stem to prevent abrasions of the bark. We do not recommend the application of any glutinous composition to the stems of trees, but only to stout paper or other material tied round them. What you have used may not do harm, but we know that harm has been done by the practice suggested, and we endeavour to advise safe methods. Read what Mr. S. T. Wright says on page 266, the issue of the 27th ult., on this subject.

Planting Yews and Hollies (*J. E.*).—Some shrubs fail no matter when they are planted, through not being in proper condition for removal. We have seen hundreds of large shrubs purchased at a low price, the possessors having been not a little jubilant in getting so much for their money. The evergreens had remained crowded and unmoved for years. As a consequence, though tall, they had few roots, and these not of a fibrous character; moreover, they were dried by exposure between the time of taking up and planting. Such examples are bound to fail. They are supposed to produce an "effect at once," and they do, but it is not very good to begin with, and in a few weeks or months decidedly bad, for they die. Yews and Hollies with an abundance of bushy fibrous roots through periodical transplanting in well managed nurseries—shrubs the very opposite in character of those above described—will grow well if properly planted in moist well worked soil, either in the autumn or the spring, though they may require to be watered and syringed afterwards if very dry weather should prevail. Large, so-called "cheap," shrubs are usually the most costly in the end. If we desired to plant a number of Yews and Hollies we should order them from a good nursery forthwith, expect the roots to be moist on arrival, and they would be planted at once. If the soil were dry we should take care to make the sites thoroughly moist before planting, also immediately afterwards give a good watering. Midwinter planting, when the ground is very cold, is not so reliable as spring planting when the buds commence swelling. We have planted numbers of the evergreens mentioned at the end of October without a failure, and many of a large size proportionately well rooted, the taking up and planting having been well done, and proper attention accorded afterwards; and we have had equal success in spring, but with more after attention, for not one out of a hundred has died. The mere "time" of planting is only one factor, and not the most important, the condition of the shrubs, soil, and methods being of greater moment in accomplishing the object in view.

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (*F. Jellico*).—The Apples are all Cox's Orange Pippin. The Pear, probably Browne Beurré; you are right about the specks. (*H. W.*).—1, Comte de Lamé; 3, Van Mons Leon Le Clerc. (*C. B.*).—1, Red Doyenné; 2, Beurré Superfin; 3, Maréchal de Cour; 4, Marie Louise; 5, Bonne d'Ézée; 6, Beurré Six. (*P. & Co.*).—1, Brown Beurré; 2, Easter Beurré; 3, Chaumontel; 4, Bergamotte Espéren; 5, Marie Louise; 6, Beurré Diel. (*Inquirer*).—1, Worcester Pomeroy; 2, Lord Derby; 3, Beurré Hardy; 4, Golden Reinette; 5, Tower of Glamis. The Plum is Cox's Late Red. (*Golden Haymaker*).—As you may perceive above, only six specimens can be named at once, and we have the best of reasons for making no departure from that rule. Moreover, probably some of the Apples you send are local. The six we recognise are—2, Betty Geeson; 3, Scarlet Nonpareil; 5, Golden Noble; 9 and 12, Rymer; 11, Dumelow's Seedling; 13, Mère de Ménage.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*Satisfactory*).—Your plant is a *Tillandsia*, perhaps *T. setacea*, but the flowers were too much withered to be recognisable. (*Amateur*).—1, *Salvia rutilans*; 2, *Salvia ianthina*; 3, *Salvia involucrata*; 4, *Salvia splendens*; 5, insufficient, no flowers sent; 6, *Panax laciniatum*. (*A.*).—*Begonia ferrea*. (*Mrs. Keane*).—The plant is *Coccoloba platyclada*, which requires to be grown in a greenhouse; in warm situations it would no doubt succeed out of doors. (*G. R.*).—1 and 2, Varieties of

Adiantum cuneatum; 3, *Adiantum concinnum*; 4, *Asplenium formosum*; 5, *Adiantum trapeziforme*. (*A Constant Reader*).—It is somewhat in the way of Mrs. Hawkins, and is worth keeping.

COVENT GARDEN MARKET.—OCTOBER 23RD.

MARKET well supplied with all classes of goods, with the exception of Apples, which have been in good demand at better prices. The first consignment of Nova Scotia Apples is on the road, and expected to be sold this week.

FRUIT.

	s. d.	e. d.		s. d.	e. d.

THE FLOCK IN WINTER.

AMONG our Michaelmas plans for the ensuing twelve months none are more important than those made for the management of the flock during winter, for it includes the most critical and important season of all, the lambing, when due care and forethought may enable us to avoid all but casual losses, and obtain a full crop of healthy lambs.

The popular notion that a certain per-centage of losses both of ewes and lambs was inevitable is now pretty well exploded, and it may be laid down positively that given strong healthy ewes that are not over age, losses should be the exception. Such a flock last season gave us rather over an average of a lamb and a half per ewe, not a lamb being lost, the only casualty being the loss of a ewe. This satisfactory result was, of course, owing in some measure to good management during the lambing, but it was very much more an outcome of intelligent care the year round, and especially in winter. Let us see what is best to be done for the ewe flock for the next three or four months.

The period of gestation for a ewe is twenty-one weeks, so that if the tups were turned in the first week in September the first lambs may be looked for about the last week in January. From the present time, therefore, the ewes are to be considered as pregnant, and especial care must be taken to guard them from being hastily driven. The shepherd's dog should always be used quietly, and strange dogs kept off. Many a flock has sustained serious injury by dogs breaking in at night, and we have more than once had reason to wish that the gypsies' lurchers could be put down by law, for many a flock has been sadly harrassed by them at night. It is for this reason that the ewes should always be driven near home or into a secure enclosure at night. Perhaps the home farmer runs less risk of harm from such a cause than others, as he has the advantage of a park with a wall or high fence.

The folding of pregnant ewes upon arable land if done at all should be during the first two months of pregnancy, and then only upon tolerably sound land. With care there need be no harm done to the ewes by folding upon early Turnips or Mustard, and the land is then ploughed at once for winter corn. A little dry food should also be given in troughs regularly during the folding, both to keep up condition and prevent scouring. If this is given regularly a little while before changing folds there will be no difficulty in getting them to eat it. Chaff given alone will not be touched if the sheep have access to plenty of fresh green food, but if mixed with crushed Oats and a little bran it will be eaten. In all trough-feeding only enough should be given to be cleared up at once, and the troughs should always be kept free of stale food or other filth. If the weather becomes so wet that the soil becomes sodden and very muddy in the folds the ewes should be withdrawn to sound pasture, and the folding be left to the hoggets. As was mentioned last week, our ewes are now in the park feeding solely upon the grass and acorns. They are in high condition, and should bring fine healthy lambs if only they have wholesome food and kindly treatment in December and January. It is then that so much harm is often done by injudicious feeding and folding upon arable land. It surely requires only ordinary intelligence to grasp the fact that a dietary consisting principally of cold, often half frozen, roots containing 80 per cent. of water must tax the system seriously by the frequent reduction of temperature and the little nourishment derived in proportion to the food consumed. In addition to this there is the heavy strain in walking upon land which has been churned into a mud puddle and become so tenacious that the feet can only be withdrawn with difficulty. It is true enough that strong young ewes will often bear all this with impunity, but there is usually a heavy per-centage of losses in flocks subjected to such treatment. We hold that such exposure of sheep or any live stock to the risk of health, simply because they can endure it, is decidedly a mistake from a commercial point of view. How can we expect animals to thrive if we allow health and strength to be taxed so severely?

When pasture comes to be cultivated as thoroughly as arable land most farms will then have enough sound dry pasture to carry ewes in winter. If they are taken upon this in December and fed according to the weather with what trough food, with Pea and Oat straw in racks may be necessary, they will require no roots. In January a few Mangolds or Cabbages may be given daily with advantage, but all Swede or other Turnips should be held in reserve

till after the lambing. There will then be no risk of losses by abortion, which do undoubtedly arise from the causes we have mentioned. A shepherd should have no latitude in this matter; he must either yield implicit obedience or be sent about his business. A little tact and firmness should enable one to avoid extreme measures, but the health of the sheep must not be allowed to suffer through ignorance or obstinacy.

[By an error of the printer "Salvator or Mountain Ash" Wheat appears in the second paragraph of the Home Farm article last week, page 346. It should have been "Salvator or Mountain White."]

(To be continued.)

WORK ON THE HOME FARM.

Never was there a better provision of food upon the farm for live stock. Hay and stover of the best quality, an abundant crop of roots, Cabbage, and Kale, plenty of straw of all kinds, to say nothing of silage, which now takes a leading place upon many a farm. The layers for another year are full of plants, and autumn sown green crops, such as Trifolium, Rye, Winter Oats, and Tares, are all up and growing freely. Late Turnips have been sown more extensively than usual, and there will be plenty of such food in store for lambs next spring. Turnips are so plentiful that we are assured by a large flockmaster he is offered as many acres as he requires for some 7000 sheep free of cost. Farmers will thus get their land manured in readiness for spring corn, but we greatly deplore such evidence of a want of capital by so many farmers to purchase sheep for their own requirements. There is undoubtedly a scarcity of sheep among tenant farmers, and capitalists have seized the opportunity to purchase sheep and put them out to feed among needy farmers. The high price of sheep in this country has not escaped the attention of the foreigner, and importations are on the increase, considerable consignments coming from Norway, and we have even heard of some useful consignments from Lapland.

Dairy cows still have an abundance of grass, and the butter retains the high colour and full flavour of summer. There is no doubt that much good is being done by dairy schools and butter-making contests. We approve of a recent suggestion that trained dairymaids, or some of those young ladies who lecture so charmingly and demonstrate so clearly upon butter making, should be engaged by farmers to visit their dairies and inspect and advise what is best to be done under the peculiar conditions existing at each farm. We have no doubt much good might be done in this way, but we fear many a worthy farmer's wife will be slow to comprehend the value of granular butter. We were recently assured by a keen commercial man that good butter was very much owing to climate. No doubt some such ideas, or mere carelessness and prejudice, hinder the progress of dairy reform among those most interested in it, and yet it is all so very simple, and there is no insuperable difficulty in the way of making really good butter anywhere in this country.

COMPETITION FOR MALTING BARLEY.—We are requested to insert the following paragraph:—There is a large competition at the Brewers' Exhibition, London, this week for the valuable prizes offered for Malting Barley. The Champion Cup, open to the world, as well as first, second, and third prizes, have been won by Webbs' Kinver Chevalier Barley. This is the third year in succession that this variety has won the premier honours at the Brewers' Exhibition. Webbs' Kinver Chevalier Barley was introduced by Messrs. Webb & Sons, The Queen's Seedsmen, Worsley, Stourbridge.

REMARKS.

- 13th.—Fine and generally bright, a little misty early and in the evening.
 14th.—Foggy early, fine bright day, fog again in evening.
 15th.—Fog till 9 A.M., then fine and bright with solar halo about midday; cloudy after 2 P.M.
 16th.—Cloudy, with occasional sunshine till 4 P.M., then very wet till 10.30.
 17th.—Generally bright, but cloudy at times in afternoon.
 18th.—Foggy early; fair day; rain after 10 P.M.
 A very ordinary week, terminating, however, with a sharp fall of barometer, and heavy rain on Saturday night and Sunday morning.—G. J. SIMONS.

MANY erroneous statements have appeared at different times with regard to the introduction of the Chrysanthemum to England, and these divergencies are undoubtedly due to the paucity of early reliable records bearing upon the matter. Like many other plants of eastern origin the Chrysanthemum had been cultivated in the eastern part of Asia, more particularly in China and Japan, for many years, perhaps centuries, before it became known to Europeans, and then its existence was first recorded in botanical works. During the seventeenth century the Dutch were foremost amongst commercial navigators, and their merchants were in frequent communication with the East Indies, the larger islands of the Indian Archipelago and neighbouring regions, probably occasionally even with China and Japan, though ports in those countries were then very difficult of access. Amongst the various natural and artificial products imported to Europe by this means it was quite likely that plants would be included, and we know this actually to have been the case with some now familiar occupants of our gardens. There is a strong probability that the Chrysanthemum thus originally found its way to Holland, at least the earliest known references are in Dutch works of the years 1689 (Breynius) and 1690 (Rheede), and from these it appears that varieties with differently coloured flowers were then cultivated. Respecting these introductions our information terminates with the records named, and no further facts are forthcoming; indeed the plants disappeared, and nothing further is heard about them in cultivation for a hundred years. Botanists and travellers had, however, been busy in the meantime, and Kämpfer, Rumphius, Linnæus, and Thunberg all described the plant, under various names it is true, but it was comparatively easy to identify them all with the Chrysanthemum indicum of Linnæus, which became its accepted name.

We learn on the authority of Aiton's "*Hortus Kewensis*" (second edition, 1813) that about the middle of the eighteenth century a variety of Chrysanthemum indicum was cultivated by Miller in the Apothecaries' Garden at Chelsea (1764), and a specimen was preserved in the official herbarium, though the plant was lost. Some discrepancies between the description and the specimen throw a little doubt upon the identity of the plant with the C. indicum of Linnæus, but there is no question that it was subsequently lost, and like the earlier introduced varieties in Holland, totally disappeared from gardens. It is also clear the plant was unknown at Kew when the first edition of the "*Hortus Kewensis*" was published (1789), for it is not included in that work.

The next introduction of which we have any record is said to have occurred in 1789, a Monsieur Blancard of Marseilles being credited with the importation into France of several varieties described by M. Ramatuelle as *Anthemis grandiflora* in the *Journal d'Histoire Naturelle*, vol. ii. page 237. Mr. Sabine, Secretary of the London Horticultural Society, in 1822, published in the *Transactions of the Society* named (vol. iv.) a list of the varieties then known, with particulars of their origin, and a brief history of the Chrysanthemum, to which (with Mr. Salter's book) subsequent writers have been largely indebted for their materials. In that paper it is said some varieties of Chrysanthemum were introduced to France by M. Blancard in 1789, and that in the following year (1790) plants of the purple variety, the only one preserved, were sent to the Royal Gardens at Kew by M. Cels of Paris, and thence distributed in England. We thus have the two dates upon which the centenary celebrations of the present and next year are founded.

The progress of the flower from the period named becomes a matter of history, concerning which much has been written, but no complete and satisfactory record of its advance during the past fifty years has yet appeared. It is only within the later half of that time that really rapid progress has been made, and regarding the Chrysanthemum collectively in all its sections it is unquestionably greatly superior to what it was a quarter of a century ago, when some thought its popularity was declining, and neglected it for fresh favourites. The progress of recent years has been almost entirely due to British cultivators, who have produced the best examples of their skill and entered in competition with each other at the exhibitions which have so greatly increased in numbers. No history of the Chrysanthemum can be regarded as satisfactory that does not do full justice to those who have really proved to the public the beauties and capabilities of the plant, and without their aid the continental raisers would have received but little encouragement to proceed in their work. As it is the latter have annually left much for our nurserymen to do in the selection of really good novelties from the extremely numerous seedlings sent here with elaborate descriptions of their charms. To the firms that have introduced varieties direct from Japan we are much more indebted, as these have formed very distinct types. Raisers of seedlings in England have done good and useful work; critical selectors, and those who have observed and fixed distinct sports, have all assisted in the advance; while many firms in town and country who make specialties of Chrysanthemums and provide annual displays, have all helped in the popularisation of the plant. Then, too, the public shows in the Temple Gardens and Finsbury Park, and more recently in the Victoria, Southwark, and Battersea Parks, are bringing the Chrysanthemum into more prominent notice. Lastly, the writers of books and contributors to the Press have performed valuable service in rendering the usefulness and beauty of the plant more widely known, and in the support of the societies devoted to its encouragement. We thus have four agencies that have shared in the development of the Chrysanthemum to its present stage of beauty and popularity—the introducers and raisers of new varieties who have furnished the material; the amateur, professional, and trade exhibitors, who have grown and displayed them to the best advantage; the societies that have provided prizes and other honours to promote competition; and the writers who have published their experiences and extended the interest in the flower by records of events, advances, and successes. All these agencies should have due representation and recognition in any centenary celebration of so popular a plant.

Some societies have considered the present year as the most fitting for a celebration of this kind, although next year would be more appropriate as the centenary of the year when the Chrysanthemum appeared in England; and this view has been taken by the National Society, which reserves its Special Fête and Conference for 1890. It is, of course, quite open for any European country to celebrate the centenary this year, and the Royal Horticultural Society accordingly lead the van with a Conference and Exhibition at Chiswick next Tuesday and Wednesday, November 5th and 6th, to which many are now looking forward with considerable curiosity and interest. Some of this Society's former influence is returning under a spirited system of management, and it is doubtful if any other Society in the world could have accomplished such results in one year as the Temple Show, the Rose, and Vegetable Conferences, without the aid of money prizes. Perhaps a little too much has been attempted, but that is better than the policy of inactivity so long pursued, and it may be con-

fidently expected that the Chiswick gathering will not be wanting in importance and utility.

On another page particulars of the Conference programme are given, and with such a range of subjects well treated, as they unquestionably will be, there should be amply sufficient to attract lovers of the Chrysanthemum for an hour or two on each day. The schedule is a comprehensive one, but it is probable that some sections, especially those for trained specimen plants, will be rather inadequately represented. The conveyance of plants is an expensive matter, and while few gentlemen will care to become responsible for the cost, still fewer gardeners can afford to do so themselves. With regard to the cut blooms the matter is somewhat different, as a few boxes of blooms are not a very serious impediment to a traveller, nor is the carriage a heavy item. We may, therefore, hope to see some exhibitors indicating their willingness to assist in extending the display by contributing from their floral treasures. The practical usefulness of the Selecting Committee's work will mainly depend upon the number of good blooms submitted to them, for partial or restricted selection will be of little value.

At Birmingham, on November 20th and 21st, the ordinary Exhibition will be held, but to give it a special significance this year a class has been provided for forty-eight blooms—twenty-four incurved and twenty-four Japanese, distinct, with six prizes, ranging from £25 to £1 10s. It is also stated in our advertisement columns that the Exhibition "will be opened by Sir Thomas Martineau, when songs on the Chrysanthemum, specially composed for the occasion, will be sung by over 200 voices."

Edinburgh will celebrate the centenary with "an international Show," held by the Scottish Horticultural Association, on November 21st, 22nd, and 23rd. The leading classes are for forty-eight Japanese blooms (not less than thirty-six varieties), the City of Edinburgh cup, value £20, being offered as the first prize; and for thirty-six blooms, comprising twelve Japanese, distinct, twelve incurved in not less than nine varieties, and twelve Japanese reflexed in not less than nine varieties, the Scottish challenge cup and five guineas constituting the first prize.

At Ghent a centenary celebration will be held by the Société Royale d'Agriculture et de Botanique, from November 24th to December 1st, when gold, silver, and other medals will be offered in a large number of classes, miscellaneous Chinese and Japanese plants being also provided for. A deputation of members of the National Chrysanthemum Society's General Committee, comprising Mr. William Holmes, Mr. George Gordon, Mr. Lewis Castle, Mr. C. Harman Payne, and Mr. B. Wynne, has been appointed to visit this Show, as the most representative continental centenary display.

It is surprising that in connection with these various exhibitions so little attempt has been made to secure any features of an original character. Exception must, however, be made of the Chiswick and Ghent affairs, as they are both distinctly out of the ordinary exhibition lines, so far as can be judged from the programmes issued. In both these cases it has been attempted to impart more than mere show interest to the gatherings, and this is what is needed. Conferences are assisting in rendering shows somewhat more than a struggle for so many prizes and challenge vases, and there is still room for the National Society to make its celebration in 1890 distinct from all that will have preceded it.

PROFITABLE FRUITS.

THE MORELLO CHERRY.

LET me commend this Cherry to all on the look out for what is best to grow in the way of hardy fruits for either home consumption or for marketing purposes. There are several points in its favour, two especially good ones being the fact that the trees very rarely fail to bear well, it may be in positions where no other fruit could be so profitably grown, and the crops are always easy to get rid of at a good price. When the leading salesmen in Covent Garden Market have to send hundreds of miles for Morellos, paying, in addition to the cost of carriage, from 10d. to 1s. per

pound for sound fruit, we may safely assume there is both a good demand for it and a deficient supply. In this district there is no necessity to go far afield for purchasers, as the produce can always be readily sold at about the figures already given, the prices very seldom falling lower than 10d. From experience gained in other parts of the country, and a few facts gleaned from correspondents, much the same state of affairs prevails in most other localities, the supply not, as a rule, equalling the demand. This being so, the wonder is that comparatively few trees are planted, and so little is heard of the value of the Morello as a hardy market fruit. Why they are so little grown in other than the metropolitan districts may perhaps be due to the impression that they must be trained against cool walls, when in reality they succeed admirably as half standards and pyramids, the only real difficulty being to preserve the fruit from birds.

Those having high walls with cool aspects, or any, say facing north, north-east, or north-west not at present profitably utilised, ought to cover these with Morello Cherries as quickly as possible, whether the surplus or whole of the fruit is to be marketed or not. Unlike many other fruits Morellos are not quickly perishable, their season extending from August to November inclusive, and, in addition to being attractive as a dessert fruit, are particularly esteemed in pies, and also when preserved whole in brandy. Especially would I advise cottagers who occupy old-fashioned houses to procure trees, or any with cool walls which they may venture to drive nails into, though even this difficulty of driving nails into expensive walls, where it occurs, may be obviated by wiring the space. Within four miles of where I am writing there is a large Morello tree, owned by a garden labourer, that annually produces sufficient fruit to realise what has to be paid for rent, which, however, it must be added, is much below the average of most districts. His employer invariably takes the whole of the fruit, and this season 30s. was paid for it, but as much as £2 has been made of the fruit in one season, the quality and weight of the crop being exceptionally good. It is choice fruit now-a-days that sells the most readily at highly remunerative prices, and those who are anxious to succeed in profitable fruit culture ought to pay more attention to the clothing of every blank space—not necessarily garden walls—with trees of superior kinds and varieties. I would strongly advise the owners of cottages, notably the older and roomy structures, to provide the occupiers with young trees, Morello Cherries included, and see that they are properly treated and cared for. In time they will become a source of profit to the tenants, and add greatly to the letting value of the houses.

I hold the Morello to be amongst the most easily grown of all fruit, and this, whether located in the open or against a high or moderately high wall. They rarely form any extra strong or gross shoots, an even well-balanced head being easily secured, and if well fed at the roots they attain a great size and last for many years. At the outset a good border extended to at least 4 feet from the walls should be formed, and principally of good turfy loam with an addition, if need be, of a third or more of good garden soil. Although it delights in a cool position the trees do not thrive long after the roots reach a clayey subsoil. Where clay, therefore, is found within 18 inches of the surface, not less than 9 inches of the subsoil should be removed, and a layer of rough stones or brick ends faced over with old mortar rubbish be substituted, on this being placed 2 feet of the loam or compost prepared. Especially is it necessary that the site be well drained; and in very low lying positions, where the drainage is sometimes unavoidably defective, the trees ought to be, in fact must be, planted in a border raised considerably above the ordinary level of the garden. If the wall is high, or say 10 feet and upwards in height, the quickest way to furnish the space is to plant both dwarf and standards, the latter being known as "riders," and these eventually have to be removed or cut away in order to make room for those with short stems planted between them. A healthy tree well cared for is capable of covering an immense amount of wall space, one that I have seen in Kent being of such a size and so well furnished with bearing wood as to occupy one man's time for not less than four days in pruning and training every winter. As a rule the dwarf trees should be planted about 18 feet apart, the riders, if any, being disposed midway between them. Maiden trees in addition to being much the cheapest also take most quickly to their fresh quarters, and soon surpass older trees planted at the same time. These must be cut back once, or perhaps twice, in order to obtain the requisite number of branches for laying the foundation of the trees, after which all that is necessary is to lay in main branches wherever there is room for them, the young wood for fruiting the following season being reserved every summer and trained or fastened to the walls in the winter, taking the place in many instances of old bearing wood cut out. When trained trees, or those with seven or more main branches, are purchased and planted, and which is most frequently done, it is unwise to shorten these

in any way. Laid in to their full length, exactly as they were previously trained, they will attempt to fruit the same season, but this must be prevented, as it is young wood that is required. In the second year after planting they may be allowed to bear a few fruit, and every following year the crops will increase in weight.

Standard trees are still less trouble as regards pruning and training, and pyramids also, when once a good foundation has been laid, are not difficult to manage. The former ought to be on the common Cherry stock, and the latter is also preferred by me for wall trees. If dwarf bushes or pyramids are preferred, these ought to be worked on the Mahaleb stock. The ground for either of these should be equally as well prepared, or much as advised in the case of wall trees. Free growing standards to be disposed 20 feet apart each way, pyramids 10 feet, and those to be root-pruned or otherwise restricted 6 feet apart. At first all must be freely pruned in order to frame out the tree, but subsequently the treatment consists merely of thinning out the young shoots in the summer and cutting out old wood in the winter, young well ripened growths producing flowers and fruit in abundance.

Where so many err in their treatment of well established Morello trees is in imagining these will go on doing well for any length of time, whereas they require liberal root culture, otherwise the crops will be poor in quality and a collapse be the eventual and perhaps early result. Mulchings of manure and fresh loam, or the former alone, will serve to keep the roots active near the surface, but even this alone is not sufficient, and it is advisable to occasionally open a wide deep circular trench at about 8 feet from the stem of a large tree, filling this with and relaying the roots that were forked out of the old soil and preserved in a good loamy compost. All fruit trees delight in turfy loam, and none more so than Morello Cherries. Cottagers and many gardeners are not in a position to give their trees fresh loam, or indeed much solid manure in the way of surface dressings or mulchings, but they can adopt the plan of the old cottager previously alluded to as a successful grower of Morellos. During the winter he loosens the surface of the ground as far as the roots spread, and frequently empties the drainings of his pigstye over the border, sewage also going the same way. His long experience has told him that strong liquid manure would be ruinous to trees if applied when in full leaf, but during the winter it may be used safely and with the best possible results.—W. IGGULDEN.

TWO GOOD HARDY CLIMBERS.

ONE oftentimes sees inquiries about hardy climbers, and amidst the numerous additions of late years to our catalogues it is not difficult to select some which may answer all purposes. There are many purposes for which they are used, and many and various kinds of buildings for which they are adapted. Some, like the Passion Flower, are hardy in certain parts of these islands, and are grown on account of the beauty of their flowers. There are, again, others whose claim to favour depends entirely on their foliage. I am not going to enter upon any quasi scientific statement as to twining, climbing, and trailing plants, but everyone will recognise the fact that plants differ very much in their method of climbing, while some which have the name of climbers given to them have really and truly no claim whatever to the title. Some plants, like the Vine, put out thread-like tendrils with which they lay hold of anything with which they come in contact; others, like the Ivy, throw out little suckers with which it clings to walls and trees. There are others which, like the Bindweed, throw their stems bodily round anything that they can, and all who have to do with that very hardy and persistent weed know how difficult it is to disentangle it from the plant on which it has bestowed its attentions, while there are others which are no climbers at all, but merely rampant growers. Thus we see in most catalogues "climbing Roses" as a distinct section, and then amongst the Hybrid Perpetuals we see now and then a climbing Captain Christy, climbing Charles Lefebvre, &c., while in truth they have no tendency to climbing. Let any of them be planted where they could climb if they possessed the power, and we all know that without artificial aid they would speedily be all over the place. It cannot be otherwise. They have none of the appliances for climbing, and are simply those Roses which are specifically of a rampant habit, or those in which some vigorous shoot has been developed and the character of the growth been altered, more frequently by some influence of the stock. It is a misnomer, but like a great many things of the same kind, will no doubt hold its way, just as nothing will ever alter the absurd distinction of Show and Fancy Dahlias. And now for my two climbers.

AMPELOPSIS VEITCHI. — The honoured name of Veitch is attached to many plants of the most varied character, for that enterprising firm pushes its researches into all parts of the world,

while the scientific hybridising practised in their nurseries has added many a delightful flower to our lists, but I question very much whether there is one plant amongst the many bearing their name which will longer perpetuate it than this very useful climber, and although it has synonyms, being known as *A. tricuspidata* and *Vitis japonica*, yet the one by which it is usually known is that given to it here. Unlike the ordinary Virginian Creeper, it throws out little suckers, which cling closely to the wall, and so enable it to extend itself, and how varied its uses, and how happy it seems to be in any position. No one who knows the suburbs of our large towns will fail to recognise its usefulness in covering smoke-coloured brick walls. It also luxuriates in the pure air of the country. How beautiful it is covering the fine mansion of Mr. Llewelyn at Penllergare in South Wales, while all your readers will no doubt be able to call to mind many equally charming effects in other places, but I question very much whether anyone has quite utilised it as I have done. My church, which inside is one of the most beautiful and interesting of our Kentish churches, has walls which were never of any great beauty. They were built, as many in those days (A.D. 1250) were, of rubble, and hence, when the church was restored five years ago, I was desirous of covering them. I was afraid to use Ivy, as it has such an unpleasant way of getting in amongst and disturbing the drainage, so I planted on the south side some plants of *Ampelopsis*. I did not want to have anything that required nailing. The plants grew, and in course of time one of them spread itself over one of the windows. The church is very light inside, so the shade of this was not unpleasant, and when in the autumn it changed to the most brilliant scarlet, it gave all the appearance of painted glass when looked at from the inside. I hope it will not in any way injure the stonework of the window, for as it is deciduous the leaves will all be off before the heavy rains of winter set in. Should, however, I find that it is likely to do so it can be readily removed or cut away.

CLEMATIS MONTANA. — This is the other climber in favour of which I would like to write a word. In this neighbourhood it has been very largely used, and always with the best effect. The front of my house faces west-north-west, and consequently it is very difficult to get anything to grow sufficiently well to cover the walls. I tried Roses, but they were not a success. Madame Trifle and others of the Dijon section made growth indeed, but it was a straggling and bare growth, and they did not flower sufficiently well to compensate for their bad habit, so that seeing the very successful manner in which this plant had been used at one or two houses in my neighbourhood I planted one. It has now covered nearly one half of the front of the house, and in another year or so will cover the other half. I suppose that it would not be hardy in all parts of our island, and its native habitat, Nepaul, whence it was introduced in 1831, is probably suggestive of a certain amount of tenderness, but here in Kent it seems to stand the severest winters. There is one large house in this neighbourhood which is entirely covered with it, and it has stood there for a great many years. The foliage is very neat, so that even when not in flower it is pretty, and when in flower it is a sight which ought to, and does, delight all lovers of simple beauty; the pure white star-shaped flowers suggesting an enlarged Wood Anemone, are very abundantly produced, and nothing in its way can exceed the beauty of a plant well grown when in full bloom. Daily when I come in from parochial rounds have I stood in front of the house admiring its marvellous and simple beauty.

It will be seen that I have not been drawn away by any new fangled beauty in recommending two good hardy climbers. Probably others may suggest something they think to be better, but I simply record personal experience, and hope that if any of the readers of the Journal know of anything better they will kindly give us the benefit of their experience.—D., Deal.

THE BISMARCK APPLE.

As but little is known of this remarkable new Apple which is now attracting great attention, I venture to give a few particulars which may interest your readers. It is from Australia, and is there known as one of the largest and best varieties. Its name would suggest its being the pet of some German colonist. Mr. T. Francis Rivers tells me that he knew of it many years ago, but in common with others could not get trees or grafts alive from that distant country, because of the fact that when it was a suitable time to move them there we were in the height of summer, and they were unable to resist the altered temperature on the voyage. We believe that Messrs. Veitch of Chelsea and Messrs. Laing of Forest Hill succeeded at the same time in obtaining living specimens. The first fruits I saw were at the Crystal Palace in October, 1886. Messrs. J. Veitch & Sons' foreman told me they were grown under

glass, and also, that fruit from outside was very good, and that the tree was a splendid cropper. It was awarded a certificate there, and afterwards by the Royal Horticultural Society, and justly so. The examples were of the shape of Peasgood's Nonesuch, but of the appearance of Wellington, more or less marbled with rosy red markings, and the skin translucent like Wellington. I obtained plants that autumn, and grafted on Crab and Paradise; they grew freely, and from the knotted appearance of the wood and the formation of flower buds, promised fruit in 1888. This was the wet year. They flowered profusely, and set fruit their entire length (3 to 4½ feet) and appeared to promise great vigour, combined with the flaccid and somewhat folded foliage of the Hawthornden race, a family noted for productiveness. It was in appearance most akin to Small's Admirable. The rain was frequent and the sun rarely seen, yet the Bismarcks braved the elements, and severe thinning was necessary. The usual mulching was adopted, and towards September better weather came, and to our surprise the fruit grew and assumed an almost bronzy amaranth colour, and finished beautifully as many as eighteen fruits on one maiden tree with two stems. We were awarded certificates for it in the market lots and 50 variety class at the Chiswick Conference.

We sold rather too closely for much fruit this year, but with a more genial season it has been simply marvellous; trees of two years old carrying as many as eight enormous fruits of the most brilliant colour where thinned as large as 3½ inches high in a circumference of 12½ inches. Our dish of it at the Crystal Palace was conspicuous, and led many to credit us with orchard house culture. In order to demonstrate the inaccuracy of this we exhibited dishes from the open and from under glass at the Royal Horticultural Society's meeting, October 22nd, where a cultural commendation was awarded, and the Committee ruled that the orchard house fruit was fit for dessert. In my opinion it will make a good standard, as the growth is naturally pyramidal, and all the shoots turn upwards, but it is admirably adapted for bush culture. It will be many years before standards can be obtained in quantity. As far as vigour is concerned the Crab and Paradise seem to suit it equally. It is a purely kitchen Apple, possessing the brisk acidity of the Wellington, and we kept fruits till the May exhibition at the Temple.—GEORGE BUNYARD.

ORCHID NOMENCLATURE.

SOME time ago the Council of the Royal Horticultural Society called a meeting to consider what course should be taken with the object of improving the present system of Orchid nomenclature, and as a result a Committee was appointed to deal with the matter, with Sir Trevor Lawrence, Bart., M.P., as Chairman, and Dr. M. T. Masters as Secretary. It has not been deemed necessary to proceed hastily, and it was decided not to commence the meetings until October; consequently the first assembly was called for Tuesday last, October 29th, at 2 P.M., in the Lindley Library. On this occasion there was a small attendance, including Dr. M. T. Masters, Mr. J. Britten, Mr. H. Williams, Mr. J. O'Brien, Mr. W. J. Thompson, and Mr. Lewis Castle. Mr. Britten was requested to take the chair, and Dr. Masters commenced the proceedings by reading letters he had received from Mr. T. Thiselton Dyer, Mr. W. Carruthers, Mr. F. W. Burbidge, Mr. Norman Cookson, and others, making various suggestions and representing different views of the subject. Some discussion ensued, bearing chiefly upon the desirability or otherwise of adopting popular or botanical names for Orchid variations, the chief point to be considered. Dr. Masters ultimately suggested that the opinions expressed by the members present and in the letters received should be embodied in a report which he offered to prepare, to be submitted to the next meeting for consideration in detail. This course was adopted, and the Committee adjourned until Tuesday, November 12th, at the same hour—viz., 2 P.M. In addition to those above named as present the Committee comprises Mr. H. J. Veitch, Mr. F. W. Burbidge, Mr. N. Cookson, and Mr. F. Sander.

NAMING ORCHIDS.

A. B. was a very successful botanical collector and discovered several new Orchids in the East Indies and Indian Archipelago. Some of these were imported alive into Europe and are now in general cultivation, and the discoverer has received due credit for them. But he discovered several species, if not some genera, new

to science, and of which he was able only to secure herbarium specimens. On returning to Europe he sent these together with complete information and drawings of them to Reichenbach, but he has never heard anything further about them, and now they are locked up in the Reichenbach herbarium to remain there sealed from the world for the next twenty-five years. In the meantime it is quite probable that C. D., E. F., and others may rediscover these new plants in their native wilds and secure living or herbarium specimens of them, and submit them to the authorities at Kew for identification or name, and have the credit of being the original discoverers. This is very galling and ill requites the dangers, privations, and sickness A. B. underwent, his enthusiasm in the field, and his passionate love for Orchids. But it is a stinging lesson—it teaches us how unsafe it is to trust our eggs in any one man's private basket. Had Kew or some other noble, liberal, public institution of the kind been entrusted with the identification and classification of Orchids no such injustice as that done to A. B. could possibly have been done.—F. (in *American Florist*).

THE FRASER AND HALL FUND.

MR. FRED. HORSMAN sends the following list of promised and paid-up subscriptions to the Fraser and Hall fund (second list):—Sir Trevor Lawrence, Bart., M.P., £15 15s.; Chas. W. Lea, Esq., £5; Fredk. Wigan, Esq., £5 5s.; Mr. J. C. Stevens, £5 5s.; Mr. Peacock, £1 1s.; Mr. Cypher, £1 1s.; Sussex Friend, £1 1s.; Mr. H. G. Smyth, £1 1s.; Mr. Thos. Manning, £1 1s.; E. Harvey, Esq., £1 1s.; Mr. Tracey, 10s. 6d.; Horace Egerton Green, Esq., 10s.; Mr. G. W. Cummins, 5s.; Mr. C. Mason, 5s.; Mr. Bilney, 5s.; G. W. C., 1s.; Mr. Kettle, 2s. 6d.; Mr. Kingston, 2s. 6d.; Florence, 1s. Total, £39 13s. 6d.

CATTLEYA CITRINA.

A charming dwarf growing species, which thrives best on a block of wood, and requires to be hung with the leaves and pseudo-bulbs pointing downwards; it must also be placed in the cool house, the ordinary temperature of the Cattleya house being far too high for it to live in. Pseudo-bulbs small and ovate, bearing two narrow lanceolate acute leaves, which, like the pseudo-bulbs, are glaucous; scape terminal, one, or very rarely two-flowered, the whole flower large, very fleshy in texture, and deliciously fragrant; sepals oblong, apiculate; petals somewhat ovate, broader than the sepals, and, like them, bright waxy citron yellow; lip three-lobed, lateral lobes erect, but not covering the column, middle lobe spreading, somewhat ovate and undulate, white in front, citron yellow in the throat, the disc stained with orange and ornamented with several raised lines. It blooms during April, May, and June, lasting long in full beauty. Native of Mexico. 1835.

CATTLEYA DOWIANA.

A gorgeous Cattleya, evidently allied to *C. labiata*, yet abundantly distinct, and we cannot do better than quote the description of its original describer. "Pseudo-bulbs 8 inches to a foot high, slender at the base, but very much swollen in their upper portion, furrowed. Leaves one on each pseudo-bulb, oblong, thick, and rather broad for the genus, from a span to a foot long. Peduncle two to six flowered, exceedingly stout, about 6 inches long, proceeding from a spathe somewhat shorter than itself. Flowers very large and beautiful, nankeen-coloured with the exception of the lip, their total expansion nearly 7 inches. Sepals lanceolate, acute, sessile, smooth at the edges. Petals more than twice as broad as the sepals, about the same length as the lip, somewhat obtuse, very much waved at the margin. Lip oblong, crisp, very large and prominent, of a substance resembling dark purple velvet, beautifully and uniformly streaked with golden threads radiating from its centre, where they meet three other golden lines passing longitudinally. It is obscurely three-lobed, the lateral lobes being gathered round so as almost to conceal the column; the central lobe emarginate, very large, with its edges exceedingly curled. Column not more than one-third the length of the lip." It requires the warmest end of the house, producing its splendid flowers during the end of summer and autumn. Costa Rica. 1864.

CATTLEYA MAXIMA.

An extremely beautiful Orchid, but we cannot think it has the slightest affinity with *C. labiata*. Pseudo-bulbs clavate, 12 to 18 inches high, furrowed; leaves single, sometimes in pairs, ovate, oblong, obtuse, coriaceous, about 10 inches long and nearly 3 broad, bright green; scape erect, five to ten flowered; blooms large, about 5 inches in diameter; sepals linear oblong, acuminate, flat; petals broadly ovate, much broader than the sepals, with waved margins, the whole a rich rosy lilac; lip large, obscurely three-lobed, the basal part convolute, enclosing the column, middle lobe emarginate, beautifully crisp at the margin; disc smooth, ground colour white, the centre stained with a broad line of orange-yellow, the remaining portion rosy-lilac, traversed with radiating lines of rosy-crimson

shaded in some examples with purple, leaving a clear white marginal border. In some varieties the whole flower is very much paler. This species was first described by Dr. Lindley in 1844 from Hartweg's plants, but we find no record of its flowering in this country until 1855. Native of woods in Columbia and Peru and on the Rio Grande; from the latter locality the finest varieties have been introduced.—T.

A VINE ENEMY. THE COCHYLIS.

THE cochylis unfortunately has been known in France for some time, but this year it has done much mischief. At the last meeting of the Society of Agriculturists of France, M. Benoist stated that on account of the cochylis three-quarters of the champagne harvest would be lost. There is perhaps a little exaggeration in this prophecy, but it proves that so dangerous an insect must not be lost sight of. The cochylis winters under the bark in the chrysalis state shut up in a silk cocoon of a whitish grey; it is then a little creature of 7 millimètres in length, the male is bright yellow, the female darker. They are found under all shelters which can protect them against the inclemency of the weather.

At the end of April or in the course of May, according to the latitude, the moth appears. It is a yellow straw colour, with a bar of deep brown on the superior wings. The female lives from ten to fourteen days, the male not so long. After pairing the female deposits on the buds of the Vine thirty eggs or more, which are hatched about twelve or fourteen days afterwards. The caterpillars of this first generation are very small, but grow quickly, and attain almost 12 millimètres. Of greyish colour they assume in growing a violet rose tint with a brownish red head. They envelop the shoots with silk threads and some of the parts they gnaw greedily. Their development terminated, they suspend themselves on one of their threads, and hide under the leaves or in their cotton to be metamorphosed into a chrysalis. They remain in this state about two weeks. At the beginning or towards the middle of July the moth is developed and prepares a new generation. The caterpillars of this second generation show themselves in August or September, in consequence at the moment when the Grape is approaching maturity, these are the most dangerous. They penetrate into the interior of the berry, feed on its pulp and its seeds. They thus pass from one grain to another, attacking successively whole bunches. The Grape being perforated ferments, becomes brown, and later on gives a bad taste to the wine when it is in a great quantity. This caterpillar, when it arrives at its full development, is suspended on a thread like that of the first generation to form its cocoon, and passes the winter in the chrysalis state.

The double generation of which the cochylis is susceptible, and the two epochs when it appears under the form of a caterpillar, make it a redoubtable enemy. What means have we to conquer this great pest? Several have been put forward, but none give absolute results. In winter, when it sleeps in its silken envelope in the state of chrysalis, the war must be begun by removing the bark and colouring all the parts with a strong insecticide. The same should be done with the props, and the bark collected burnt where the chrysalises may be hidden. Various insecticides may be employed. First, that extolled by M. Balbiani to destroy the winter egg of the phylloxera with a base of thick oil and naphthaline; in the second place the Rohart mixture composed of carbon, petroleum, and phosphorus. Dr. Nessler has proposed a solution composed of sulphate of copper one part, soda, one part of ammonia, half fusel oil (a kind of oil residuum from the manufacture of Potato alcohol) four parts, ordinary soap, water 100 parts.

It is a good plan to water the plants with petroleum or sulpho-carbonate of potassium dissolved in water, so as to get at the chrysalises concealed in the earth. When we find the cochylis in the caterpillar state we can better combat it. Divers methods are eulogised to this effect. M. Vincendon-Dumoulin, proprietor in Dauphiné, advises two treatments with a solution composed of 100 litres of water, 3 to 4 kilogs of softsoap, 2 to 3 litres of petroleum. He spreads this insecticide, inoffensive it seems to the leaves of the Vine, once before the flowering, and again before the "veraison." M. Vincendon-Dumoulin declares that he destroyed a large quantity of larvæ and caterpillars, not only of the cochylis but of other pests. Dr. Nessler recommends the following solution:—400 grammes of soap melted in a litre of water, 50 grammes of fusel oil, 200 grammes of spirits of wine, 60 grammes of essence of tobacco. One or two drops injected with any instrument against the insect destroys it.

The method adopted against the caterpillars of the second generation are the same as for those of the first. One has in addition the opportunity of destroying the berries attacked, by sending women and children through the Vine rows. M. Folx recommends a more energetic remedy—the immediate gathering of all the crop in order to destroy at one blow all the caterpillars. But in addition to this remedy being very radical, if all the neighbours do not agree to do the same thing, the cochylis of the vineyard close by will return the following year to recommence its ravages, and a crop is lost without marked results.—(Cosmos, 10th August, 1889.)

[In the earlier portion of the above paper the cochylis is said to winter under the bark of the Vine. Later in the autumn larvæ are said to involve themselves in cocoons on the branches. Probably the places of

concealment are various. It is known to be found sometimes at the roots of the Vines. The insect seldom troubles Vines in houses, preferring those on walls, espaliers, or slopes of hills. Its proper scientific name is *Onectra pilleriana*. It has not been proved to occur upon the Vine here.]

ROYAL HORTICULTURAL SOCIETY.

OCTOBER 22ND.

SCIENTIFIC COMMITTEE.—Present—Mr. McLachlan, in the chair Mr. Morris, Mr. Veitch, Dr. Oliver, Mr. Symons, Dr. Scott, Dr. Muller, Mr. Michael, and Rev. G. Henslow (Hon. Sec.)

Rhododendron and Azalea bigener (fig. 44).—Mr. Veitch exhibited two plants raised from a cross between *Azalea indica*, *Stella* (male) and Lord Wolseley (female), a *Rhododendron* of East Indian parentage. [*R. jasminiflorum* × *R. javanicum* = Princess Royal; Princess Royal × *R. Brookeanum* var. *gracile* = Duchess of Teck; Duchess of Teck × *R. javanicum* = Lord Wolseley]. Both plants were from the same pod, but while one was about a foot in height the other was scarcely 3 inches, though six years old. The former bore a truss of orange-coloured flowers of about the same colour as those of Lord Wolseley. The corolla was somewhat smaller with not so broad a limb, and in texture approximated the *Azalea*. Mr. Henslow undertook to examine and report upon the

FIG. 44.—A HYBRID RHODODENDRON.

anatomical structure of the leaves to see if there were intermediate characters. A botanical certificate was unanimously awarded to Mr. Veitch for this interesting cross between two genera.

Peas Diseased.—Dr. Oliver reported upon the plants sent by Mr. Pownall to the last meeting, but having insufficient specimens he was unable to assign a cause for the injury. Fresh material having been received with roots attached, he undertook to report further upon it at the next meeting.

Change of Sex Induced by a Parasitic Fungus.—Mr. Plowright forwarded an interesting communication upon the effect of *Ustilago violacea* on *Lychnis vespertina*. He artificially impregnated a female plant with spores from the anthers of a male plant of *Lychnis diurna* infested with the *Ustilago*. Although the hybrid offspring raised were perfectly healthy, yet the female parent plant itself (*L. vespertina*) bore nothing but male flowers in the following year, every one of which was affected with *U. violacea*. A fuller account will appear in the Journal of the R.H.S. It was observed by members of the Committee that the explanation is that the change of sex is due to compensation. Whatever tends to lessen the vitality or vigour of the pistil may heighten that of the stamen, as occurs frequently in hermaphrodite flowers, and when they are normally unisexual then the lost sex may reappear, when the energy is diverted from the one usual present. Moreover, if the constitution be weakened, as was possibly the case in the present instance by the fungus, then the plant may be only capable of forming stamens, for it is well known that the male sex is often correlated with a lessened degree of vitality.

Oranges Attacked by the Fly.—A communication was received from Malta stating that, "The Orange fly, *Ceratitis citriperda*, has of late years done much damage to the fruits of the Orange and Mandarin trees in Malta. It has also attacked the fruit of the Pear, Peach, Nectarine

and Fig. The females penetrate the skin of the ripe fruit and deposit their eggs, and the larvæ rapidly destroy the fruit. It is believed that in the island of Malta there are four broods of the fly in the year. The fly has been observed in Italy, Spain, the Azores, and South Africa." No specimens were sent, so that no opinion could be expressed upon the matter or a remedy suggested. It was thought advisable to take this opportunity of calling the attention of correspondents to the extreme importance of their invariably sending specimens with their communications, otherwise it is quite impossible for scientific experts to return satisfactory replies.

Fog Report.—The discussion upon the injury of London fogs upon vegetation was renewed, and a circular drawn up, which will shortly be issued to growers within a radius of twelve to fifteen miles from the metropolis. The Committee trust that they will furnish as full details as possible, with the hope that the investigation may lead to the adoption of such preventives, as conditions will permit, against the increasing injury which now prevails in the suburbs of London.

The Lady Apple.—Mr. Henslow exhibited a spray covered with the brightly coloured fruit from a tree which grows in a hedge within his garden, near Drayton Green, Ealing. It is probably a descendant from some plant introduced many generations ago. It is asserted in "The Fruit Manual," by Dr. Hogg to have been brought from the Peloponnesus to Rome by Appius Claudius, and was called the "Lady Apple" because ladies in France were accustomed to carry it in their pockets in order that the peculiar odour might be imparted to their handkerchiefs. Though known to early continental writers it does not appear to have been introduced into England till the end of the seventeenth century. It was first discovered as a wildling in the Forest of Api in Brittany. Only one dish was exhibited (by Mr. Pragnell of Castle Gardens, Sherborne, Dorset) at the National Apple Congress in 1883, and one dish at the Apple and Pear Conference, 1888. Hence it would seem to be nearly extinct in England at the present time. It has little or no commercial value, though useful for decorative purposes.

Gentiana Amarilla, sub. sp. Germanica.—Dr. Masters exhibited specimens of this plant from Tring, whence it was first recorded. Hooker and Arnott, "Brit. Flor.," 1855, give only Tring and Ripon as localities, but Hooker, "Stud. Flor.," 1884, mentions York, Pemb, Herts, Berks, Surrey, and Hants. Though regarded as separate species by some continental botanists, intermediate conditions link the extreme forms together.

PRUNING AND ITS EFFECTS.

AN intelligent use of both pruning knife and saw is to be commended in cases where the work of renovation is being carried out on the lines laid down on page 216, and, it is almost needless to add, plays an important part in maintaining the productiveness of healthy trees not requiring to be lifted or root-pruned. Many err in using the knife especially too freely, and it is also possible to make a mistake in the opposite direction. I have a great aversion to long, ugly spurs on wall trees, notably of Apricots, Plums, and Pears. Of what use are the walls if the portions of the trees which only can produce fruit are from 6 inches to 12 inches away from them, or where they derive little benefit from their warmth and shelter? Not only is warmth wanted to assist in the development of clean, full-sized fruit, but is still more imperative in many districts where the growth is naturally late and the wood ripens badly. Who ever saw fine Pears, for instance, borne by long, knotty spurs? Long spurs on Apricots and Plums are certainly fruitful enough at times, but very rarely is the fruit so large or so brightly coloured as the same trees would be capable of producing if the fruiting spurs were close to the main branches. The aim therefore of would-be successful growers should be to prevent any young and as yet unspoilt trees from forming long spurs, and also to gradually reduce the number and length of any already too far from the walls.

The start may be made with spur-shortening any time after this is in print, and I am inclined to think the sooner the better. Supposing summer stopping has been resorted to, or the trees were pruned after the lateral growth was well advanced towards maturity, all being pruned to within about 4 inches of their starting point, those on trees not previously spoilt by the neglect of this precaution ought to be still further shortened to a length of about 1 inch of the main branch. Persevere with this practice every season, and in the course of about three years a good cluster of fruit spurs should result. If the trees are too vigorous, and nothing but wood buds followed by strong lateral growths result, then in some instances nothing but partly or wholly lifting them will correct this unfortunate state of affairs. Not unfrequently, however, the practice of laying in all leading growths required for furnishing blank wall spaces, or any thin places among the older branches, to their full length, has an excellent effect on the productiveness of a tree. These leading branches, if well ripened, will usually develop fruit buds at nearly every joint and good crops of fruit, and is an excellent preventive of grossness, the fruitful habit gradually extending to other parts of the tree. On no account should well matured leading shoots be topped or shortened back, however

slightly, as this is certain to defeat the object in view; in fact, unless they, if pruned at all, are cut back to about one-third of their length the greater portion as a rule will not even be furnished with laterals next season.

Much may be done in the way of reducing the length of old spurs by foreshortening, but in many instances the more drastic measure of sawing them off cleanly to within 1 inch, or even closer, to the main branch ought to be resorted to. The former is perhaps the slowest method of the two, but if persisted in every autumn till such times as the spurs are all sufficiently close to the branches there will be no appreciable falling off, but rather the reverse, in the weight of the crops, while the quality will be gradually improved. Foreshortening in this case merely consists in cutting back the longest spurs to a well-placed bud or cluster of buds much nearer the branch, and if this is done piecemeal the greater portion will push out back buds, and an improvement in every way soon becomes apparent. Long naked spurs cannot be treated in this way, but as these are usually found on trees too densely clothed with so-called bearing wood the removal of one half of these would act beneficially, even if many of them failed to break afresh round the stump left. The trees I have served in this way, the work of thus freely shortening back being extended over two or three years, have failed to break freely in a few instances only, and none need be afraid to adopt the plan, as the trees must be in a very miserable plight at the roots if they fail to respond to knife or saw. The spurs on several of the Pear trees, the roots of which we gradually lifted and relaid in fresh soil (see page 216), were extensively sawn off, and not a blank space on the main branches is to be seen. A tree of Vicar of Winkfield, which covers a wall space 24 feet by 12 feet, this season produced twenty-four dozen fine clean fruit, and the crop was nearly as heavy last year. Another equally large and healthy specimen on the same wall (aspect east) and similarly treated produced nearly twenty dozen fruit in 1888, and this week we have gathered eleven dozen fruits from it of extra good size and appearance. The quality of neither of these old favourites is usually considered first class, but unless I am much mistaken few lovers of fruit would condemn either as grown and ripened here. Marie Louise has greatly improved under this process of top and bottom renovation, and the same may be said of Glou Morceau, Louise Bonne of Jersey, Winter Nelis, and Easter Beurré. I ought to add that we take particular care not to drag off old spurs with a part of the main branch attached, as they are either cut with a strong sharp knife or are sawn off, the wounds being pared and smoothed with a knife.

Not only is it advisable to replace old spurs by short new ones, but in the case of Apricots and Plums especially worn out or stunted old main branches may often with advantage be replaced by young ones. Sometimes it is necessary to cut back a few of the main branches to near the main stem or base of the tree, in order to obtain the requisite young shoots for laying in, while in others they are naturally produced where most needed, and in this case those they are to replace need not be cut out till the young ones are two or three years old. Not a few Plum trees, notably where the head room is much restricted, form a thicket of lateral growths at the top of the wall, the lower portion of the main branches being very badly furnished with fruiting spurs. Either these top-heavy branches ought to be freely shortened back, so as to promote the formation of shoots nearer the bottom of the walls, or else the long spurs must be sawn off, and more care taken of the lower shoots that may be formed, and also in pruning the laterals resulting from the stumps. When trees grow thus strongly near the top of the walls those in charge, or it may be the owners, are apt to let them to extend as much as they will, the consequence being a bushy head fully exposed to all weathers, the rest of the tree gradually getting weaker and still more useless. It may be urged that these more naturally grown heads are frequently much the most productive part of the trees, and this I readily admit is the case; but the proper place for standards are in the open, as walls ought to be more profitably utilised.—CULTIVATOR.

TREE CARNATIONS.

I AM glad to know that the opinion of "W. S." coincides with my own in regard to the great value and undoubted floriferousness of the two varieties of these beautiful flowers, the good qualities of which were enumerated in a recent note of mine. I am also pleased to hear that your correspondent has been successful in flowering satisfactorily all the varieties of Carnations he has yet tried; and although he does not quite agree with me when I say that some of the most beautiful of the varieties bloom but little till the spring months, I think he will go so far as to admit that among the varieties he mentions some flower much more freely during the dull months of November and December than do others under precisely the

same treatment. Assuming that "W. S." will concede the point so far, the real difference that exists between us on this subject is only of a comparative nature, and in drawing attention to the sterling qualities of Valencia and Miss Joliffe I wished to point out how much superior they were to many varieties of great beauty, but which, if compared with those indicated, are found wanting in floriferousness during the two months of the year when these lovely and deliciously scented flowers are especially valued. Take for instance the following varieties, the flowers of which are always esteemed when they can be had—Oscar and Empress of Germany. True they produce flowers occasionally before Christmas, but it is not till the turn of the year that they will bear comparison with Valencia and Miss Joliffe for yielding quantities of flowers from a 5 or 6-inch pot. Still they are valuable for supplying their finely marked blooms during the early spring months, and I quite agree with "W. S." that Carnations are appreciated at any time of the year; but to all who require a good supply of blooms from the present time till Christmas, I say, Do not depend on these, but select those varieties that have a natural tendency to flower profusely during that period. "W. S." does well to attach great importance to early propagation and liberal treatment, as without these aids good results can never be obtained; but given the same favourable treatment some varieties flower much better from November to January than others do. What say other readers of the Journal?—H. DUNKIN.

STORING ROOTS.

WHERE vegetable roots are required in variety and quantity all the year round it is imperative that as little loss through decay should be sustained as possible. Having tried various expedients to preserve roots, more especially Carrots, during the late winter and spring months with more or less success, I find freshly gathered or collected leaves the best of all material for this purpose. Anyone who may have experienced failure through using sand, ashes, mould, hay, or other unsuitable covering would do well to spread a slight layer of 2 or 3 inches of Oak, Beech, or Chestnut leaves (if mixed all the better) underneath the roots, and after leaving the latter a few days to dry partially cover with 3 or 4 inches of the same mixture, and in anticipation of severe weather setting in a few inches more may be added later on in the season. Since adopting the above simple plan we have had little loss comparatively amongst a quantity of Carrots, Beetroot, Turnips, and Parsnips stored away at this season for several years past. Believing the above hint might be useful to some inexperienced grower of either one or all of those very necessary vegetables is my only excuse for desiring a small space for so simple a subject in the pages of this important horticultural work, "the Journal."—W. H. CHISHOLM.

[No excuse is needed for communicating useful hints, and those on so-called "simple" matters are often of substantial service to many readers.]

INSECTS OF THE FLOWER GARDEN.

(Continued from page 265.)

If we examine the walls of tool houses and garden sheds in the autumn and winter months, especially those that are but dimly lighted, we often find moths of various sizes at rest, awaiting the approach of a brighter season, when they may deposit their eggs. It would hardly be fair to condemn these to death indiscriminately, as some of them are not likely to be the parents of destructive caterpillars, but others may be, hence the advantage of gardeners having sufficient entomological knowledge to enable them to recognise the commoner insects in any of their stages. One of these hibernating moths not unusual on palings or under cover is the Hebrew character (*Toenocampa gothica*), which gets its familiar name from a peculiar mark on the fore wings, which are purple brown tinged with grey, and remarkable for having scales which seem raised above the surface. Its caterpillar is found in June, being rather conspicuous for its markings of yellow and white upon the pale green ground colour. It occurs both in shrubberies and flower gardens. Mr. Doubleday found it eating the Laurel or Sweet Bay, which most caterpillars avoid. It would probably be a much more abundant species were it not for the exertions of insect-eating birds. Those that escape all two-legged and parasitic foes bury in the earth to transform themselves to chrysalides, emerging in the autumn just in time to regale on the sweets of Ivy bloom ere they repose.

The very variable moth called the dun bar (not Dunbar), also *Cosmia trapezina*, is only occasionally seen in gardens, nor is its caterpillar a frequent visitant, but it must be regarded as a useful species, and one to be protected. Indeed, it would be an advantage

to introduce the caterpillar in gardens, for though it eats the leaves of some trees, such as the Oak and Hornbeam, its chief food is the juices of other caterpillars, which it hunts eagerly. One of its favourite objects of attack is the caterpillar of the winter moth, so mischievous to our fruit trees during May and June; of these it destroys large numbers some seasons. Possibly the abundance of this caterpillar in 1889 is partly attributable to a scarcity of its insect enemies such as the above. The dun bar caterpillar, however, is no wise particular, and chases any other it can get near unless it be hairy, but as its movements are not very rapid some escape by crawling rapidly or dropping. This caterpillar has a small head and plump body of dusky green, distinctly marked with five whitish stripes running from head to tail, and scattered over the surface are rows of black warts, each surrounded by a white ring. It appears to pass the winter in the caterpillar state.

The caterpillar of the angle shades moth (*Phlogophora meticulosa*) is one of those which I have taken on Chrysanthemums, plants not generally attractive to caterpillars. It prefers, seemingly, other composites more succulent and less aromatic, and also feeds on Primulas and various low plants in gardens, continuing to nibble the leaves through the winter when the weather is mild. In form this caterpillar is rather leech-like, and if alarmed it coils into an imperfect ring; the colour is green or greenish brown, a white line runs down the back, and one upon each side of the body. Upon the thorax of the moth are long tufts of hair, and the wings, which are grey, have angulated markings of brown or green, which suggested the English name. Some years ago a nurseryman at Norwood, Surrey, called my attention to his China Asters which had been disfigured by the pretty caterpillar of the star-wort moth (*Cucullia asteris*). It is sometimes seen in gardens, and occurs also in woods upon the wild Golden Rod, to which it is partial. This is a slender caterpillar, each extremity being narrowed, the general colour green, with three yellow and two blue stripes. It is, I suppose, from the appearance of the caterpillars that the moths of this genus have as a group received the name of "sharks." One of the larger species feeds on the leaves of the wild and the garden Lettuce, concealing itself by day amongst the loose soil.

In both the kitchen and the flower garden the moth called the Silver Y, and also the Gamma (*Plusia Gamma*), is often to be seen flying about in broad daylight, but it is also to be observed at dusk, and later, nor should I be surprised to see a specimen on the wing at midnight or early morning, for it is a restless species. As the moth is about all through the summer months most years there must be a succession of the caterpillars, which feed upon a variety of plants, preferring culinary vegetables; but owing to the attraction of fragrant honey-yielding flowers have for the moths they resort to the beds and borders, as a consequence sometimes depositing eggs there upon Dahlias and Hollyhocks or on humbler plants. Hovering over flowers, the gammas vibrate their wings so rapidly that they are hardly noticeable, and when it is dark their eyes shine like tiny stars. Since a single moth will visit many flowers in one day this must be one of the species that assist in the fertilisation of plants. It is a moth remarkable for the silvery mark, compared to the English Y or the Greek letter Gamma, placed in the centre of a deep brown patch upon the forewings, the general colour of which is a glossy grey. The caterpillar producing it has the habit of looping up the middle of the body like those of the Geometrine moths; the head is smallish and the tail thickened, the colour lightish green striped with white and yellow; it is commonest in the early summer, but also occurs towards autumn. A remarkable fact in its history is the alarm caused by its appearance amongst pot herbs in some continental countries, the people being under the delusion that it imparted a poisonous quality to any leaves it touched. The mouse (*Amphipyra Tragopogonis*) has received its odd English appellation from the peculiar way in which, when alarmed, it runs along any flat surface very much as a mouse would. It is a dull-coloured moth with no particular markings, appearing about July. The caterpillar feeds in May and June, when it is not uncommon in some flower gardens, eating the leaves of a variety of plants, but showing a special liking for Larkspurs. It is one of those caterpillars that is best got rid of by examining the plants at an early hour, as it hides during the heat of the day. The head is almost hidden by the next segment of the body, which is velvety and smooth throughout, sometimes light green, or it may be greenish brown. Specimens of the first sort have yellowish stripes, but the darker ones have them white.

The caterpillars of the moth called the Gothic (*Nænia typica*) are just about this time preparing to lay up for the winter, seeking out nooks amongst Box edging or in some corner of a rockery, or any partially sheltered spot. They are as yet small, making the chief of their growth in the spring months, but they feed in little companies during part of September and October upon herbaceous plants along the borders. I have more than once found them infesting the lower leaves of the Chrysanthemum, but I think this

is exceptional. A curious thing is that the moths lay their eggs upon fruit trees, and after they have fed a week or two the young caterpillars travel down to visit garden plants. In colour they are dark brown with some white lines and black dots. Probably the moth received its name from the numerous crescent-like spots upon the wings.—ENTOMOLOGIST.

OSIER CULTURE.

CAN you give me any information upon the culture of Osiers, naming the best sorts and the probable profits to be derived?—C. M. S.

Our correspondent will find what he requires in the following article, which appeared in these pages some time ago :—

Plantations, or large beds of Osiers, might be very advantageously grown in almost any soil—such as banks of rivers, drained moors, &c., and, annually cut, would produce a sum of money that I have no doubt would largely remunerate the grower. And from land that cannot otherwise be made available for tillage, notwithstanding the vicissitudes of seasons, taking good and bad under view, the writer has experimentally ascertained that an acre of Willows or Osiers will often bring the grower a larger sum of money than an acre of Wheat; and likewise from land that would be almost useless for other kinds of crops. It is rather astonishing that the growth of them is not more attended to both in England and Scotland. As regards the nature of the soil and subsoil suitable for growing them in to the best perfection, Osiers delight in banks of rivers or drained moors, and are greatly invigorated by occasional floods or irrigations. Plantations of them may also be formed, and will succeed well, on low spongy bottoms along the margin of streams, in almost any lowland district of Britain.

In the great majority of farms are to be found level, marshy, wet spots, which, by drainage cannot well be made available for tillage, and which might be planted with the Willow, and would afterwards recompense the proprietor or farmer in a twofold way. The land might be prepared in various ways for this crop, owing to the extent and nature of the soil. Where the land will admit of being ploughed and harrowed, and has formerly undergone cultivation, I find that, at the present prices of Willow-sets or plants, and the expense of labour, it would not cost more than £8 15s. per English acre, allowing the plants to be planted at a distance of 28 inches by 18 inches apart. But I find that for plantations of any considerable extent for Osiers the ground should be formed by the spade into beds of from 8 to 9 feet broad, with intervening furrows or narrow ditches to carry off the water. The plantation may be made at any time between the fall of the leaf and an advanced period in spring; but the two last weeks of February and first week of March are the most proper times for planting the Willows. Cuttings 15 inches long should be taken with the knife on an upward slope from well-ripened wood of either two or three years' growth; experimental trial convinces me they grow more luxuriantly when planted about two-thirds of their length in the ground than when they are less deeply inserted.

I can learn from frequent trials that, where depth of soil can be obtained, Osiers succeed best in a deep, moist, free soil—ground to be dug to the depth of 24 inches, with a small quantity of dung and old lime rubbish put in the bottom of the trench. When Willows are planted in stiff tenacious soils they are much more tardy in growth, and very liable to the ravages of a brown bug, which is accompanied by a black caterpillar, often making great ravages. The ground should be hoed and kept clean; the space will well admit of this, as Osiers should in no case be planted closer than 27 inches by 18 inches apart. The expense of preparing Osier plantations by spade-work in this way of course depends much on the nature and situation of the land; but in ordinary soils drains can be cleared out to the depth of 30 inches by 22 inches broad at surface, having a scarpment, leaving it 12 inches broad at bottom. This form of a ditch can be made at from 5½d. to 6d. per perch, and the ground of an English acre, trenched and prepared to the depth of 2 feet, for £6 10s. 6d., or nearly so, and planting performed at about 18s. per English acre. The Willow, for the use of the basket maker, should be cut every year slopingly with the knife, within three buds of the point whence the shoot issued, and will admit of being cut back once in three years for the use of the cooper, exactly to the swell of the shoot of the three years' growth, thus compressing the plant back to its ancient dwarf form, at the same time realising a handsome return.

Moreover, by treating Osiers in this way they will last and produce well for a great many years. The ground should be deeply stirred with the hoe and kept clear of weeds; but digging with a spade around the roots of Willows often proves very hurtful to the fibrous feeders, as we often meet with a great portion of such oozing and growing very near the surface of the soil. Plantations of Osiers thus treated, notwithstanding the vicissitudes of the seasons, will bring the grower at least the sum of £12 sterling for every year after they arrive at their full growth. This sum of £12, I have minutely tested, can be at the present time realised from an English acre of Willows, after all expenses of cleaning and cutting-down the crop are adopted.

The Best Varieties and Most Profitable Applications.—The kinds most approved of for pollarding, coppice wood, fuel, poles, or bark, are the Huntingdon Willow (*Salix alba*), and a variety called the Red-twigged or Bedford (*S. Russelliana*).

The best sorts for Osier grounds are—First, the common Osier (*S. viminalis*); second, the Red Osier (*S. rubra*); third, the fine basket Osier (*S. Forbyana*); fourth, the Velvet Osier (*S. mollissima*); fifth,

the Long-leaved Willow (*S. triandra*); sixth, the Golden Willow (*S. vitellina*). These are the sorts most esteemed for the various purposes of the basket maker, the cooper, and the turner. The way in which Willows are most commonly disposed of, after being cut, is they are sorted into trusses and tied into bundles of 2 feet and sometimes 2 feet in circumference, and if intended to be stripped of their bark they are set on their thick end immersed a few inches in standing water, and left there until the latter part of the following month of May.

It has of late been asserted by various respectable parties that as high a sum as from £13 to £14 of nett profit, and sometimes more, could be derived at the present time from an English acre of Willows, under very ordinary treatment. They succeed best in northern exposures provided they are not over-topped. Should the ground be at all suitable for the crop, each set will produce in the first year two good basket rods, or 24,000, worth 6d. per 100 of 120. The second year, the sets being much stronger, will produce on an average six rods, one more or less being considered a very common number, one of which may be left on each stock for hoops, and the remaining 60,000 cut for baskets, which would be worth much about £24 sterling. By the third year there ought to be at least 12,000 hoops, worth 4s. per 100 of 120, and from 28,000 to 29,000, worth at least £13 10s.

These results may be obtained even by fair cultivation under ordinary circumstances. Of course it may sometimes be difficult to obtain a ready market or sale for the basket rods; the hoops we find to be always such, and much sought after. The greater part of those used in Ireland are imported and much sought after also, with commonly a very scanty supply. No hoops should be left by the third year on the plants, as the rods which grow under the shade of the hoops are seldom or ever strong enough. Mr. Phillips of Ely in England, was one of the greatest cultivator of Osiers at the close of the eighteenth century and beginning of the present, and he always obtained from £12 to £18 per acre, according to the fluctuation of prices, after deducting all costs of labour, &c.; the Red Welsh Willow (*S. purpurea*), and the White Welsh (*S. helix*), being at that time the two leading and favourite sorts, they being at that time disposed of in bunches an ell in circumference, after being peeled and whitened, by compressing them in an iron hoop to this size. If the plants be not in any way destroyed by insects, to which in some years they are subject, under good cultivation upwards of £10 could, at the present time, be realised of nett profit, after deducting all expenses of labour, from an English acre of Osiers; and although an old adage in Lincolnshire, it is nevertheless still true, that "a Willow will buy a horse before an Oak will buy a saddle." As to what towns and countries they are in most request, we find them in request in a great many large manufacturing towns and seaports, more especially in Dublin. The butter trade in Ireland causes a great consumption for hoops for butter firkins throughout the season. I have witnessed hoops of Hazel and Black Sally, as it is termed, sold at 12s. and 13s. per 1000, and the cooper cut them at his own cost; and in Dublin there is the Institution for the Blind, that requires to import a great many yearly to keep their hands employed. A much greater consumption for Willows might be relied upon were they but more extensively cultivated. An accurate calculation has been made that at least 6000 acres of Willows could readily be disposed of in Scotland and England, at prices that would very handsomely remunerate the grower.

CHRYSANTHEMUM CENTENARY CONFERENCE AT CHISWICK, NOVEMBER 5TH AND 6TH, 1889.

AMONGST the celebrations of the centenary of the introduction of the Chrysanthemum into Europe, organised at Edinburgh, Toulouse, Ghent, and other centres of horticultural activity, the Exhibition and Conference to be held by the Royal Horticultural Society in the gardens at Chiswick should prove conspicuous for interest, for the metropolis is, before all places, the home of the eastern flower.

It is arranged that an historical display of flowers grown by the Society will be made in the great vinery at Chiswick, November 5th and 6th, this being supplemented by collections of plants and flowers contributed by cultivators, many of the most eminent of these being members of the Managing Committee. The schedule for the Show consists of thirty-six classes, and although in some few of these the usual practice of "dressing" the flowers will be allowed, the general purport of the classes is to ensure the finest and most representative examples of natural development, the skill of the cultivator stopping short at the point where intentional modification of form begins. Thus in the classes for plants there are some special places reserved for such as are best adapted for decorative purposes, apart from the "finishing touches" of the florist, while in several classes for cut flowers the specimens are to be accompanied with natural foliage, and are to be shown as cut from the plant. In certain classes dressing will be allowed, and will be carried to the highest point by experts; but the natural growth of the same varieties will appear with them, to afford instructive contrasts

between the alloy and pure metal. The intellectual part of the entertainment will consist in the reading of papers and the discussion of points of interest by the President, T. B. Haywood, Esq., member of the Council; by Mr. C. Harman Payne, on the history; by Mr. E. Molyneux, on new varieties; by Mr. J. Wright, on judging; and by Mr. Shirley Hibberd, who will recount the progress made. These five will furnish the matter for the discussions of the first day. On the second day Mr. F. W. Burbidge will discourse on the production of seed, Mr. C. Orchard will explain his method of dwarfing plants, Mr. C. Pearson will treat on cultivation for market, and Mr. W. Piercy on the production of early varieties. Another important feature of the undertaking is the appointment of a series of Committees of experts, who will critically examine the whole of the varieties exhibited, and name the best amongst them for various purposes, to furnish a body of authoritative information for the benefit of the general public.

THE time is now fast approaching when it will be proved whether the Conference in connection with the celebration of the centenary of the Chrysanthemum arranged by the R.H.S. will prove a success or not. From what I hear, and the evident interest which is being taken in it by Chrysanthemum growers, it bids fair to be quite a success. Let us hope that our expectations will be realised by a good muster of the lovers of the flower, and by a good exhibition also. The executive Committee has made all reasonable arrangements to ensure success, but one omission in the schedule has been pointed out to me which I think needs mentioning. In the cut bloom classes fourteen and fifteen, twenty-four distinct blooms of incurved and Japanese are asked for. Except for very large growers this is a difficult class to fill satisfactorily. The omission is that a class for twelve distinct blooms was not made to enable those cultivators to send the latter number who were not in a position to send twenty-four distinct varieties. This objection to the schedule classes is, I think, quite reasonable, and speaking on behalf of the executive Committee, I should say that if any cultivator can bring a stand of twelve distinct blooms in any section he would be welcomed, although such a class is not specified in the schedule. It is gratifying to find that so much interest has been taken in filling up the forms for statistical returns. There are still, however, many forms distributed which have not been returned, and if any person would desire one I shall be pleased to forward it at once. The Council of the R.H.S. are anxious to issue the report of the Conference in their Journal for December. Therefore for the purpose of tabulating the returns I ask all those who have not done so to kindly send in their returns by the middle of November either to the Rev. W. Wilks or to myself. Much information may be gained we hope by the exhibition of appliances for growing and showing Chrysanthemums, which we expect will be largely represented. This will be an excellent opportunity to display any new invention which is likely to be an improvement on existing methods.—E. MOLYNEUX.

NATIONAL CHRYSANTHEMUM SOCIETY.

A MEETING of this Society's Floral Committee was held at the Royal Aquarium, Westminster, on Wednesday, October 23rd, at 2 P.M. Present—E. Sanderson, Esq., in the chair, and Messrs. H. Ballantine, W. Holmes, George Gordon, Lewis Castle, C. Gibson, R. Dean, George Addison, H. Bevan, W. Boyce, J. P. Kendall, J. Wright, and W. Mardlin. The principal collections of blooms, including many novelties, were contributed by Messrs. H. Cannell & Sons, Swanley; Messrs. J. Laing and Sons, Forest Hill; Mr. R. Owen, Maidenhead; and Mr. Fraser of Camberwell, the last named amateur having a stand of twelve fine Japanese blooms, capitably representing E. Molyneux, Edouard Audiguier, Madame C. Audiguier, and Val d'Andorre amongst others. Certificates were awarded for the following.

Madame Louise Leroy (W. Fyfe, Overston Park Gardens, Northampton).—A handsome Japanese variety, with large deep substantial pure white blooms, the florets long, flat, or fluted, and slightly twisted.

President Hyde (R. Owen).—A Japanese reflexed variety with medium-sized compact blooms of deep rich golden colour, the florets fluted and recurving.

Thomas Stephenson (R. Owen).—A sport from Criterion, which appeared last year, and was not considered sufficiently distinct. It has also been shown this year of a lighter colour, though several have tried it in large collections this year and find it distinct. This was the opinion of the Committee with regard to the blooms shown by Mr. Owen, which possessed a rich salmon red colour, more like it is at Swanmore Park, and in this state a decided acquisition.

Victorine (R. Owen).—This is a small elegant deep red Pompon, remarkably free and dwarf, and it was commended for cutting, the blooms not being considered quite large enough for show purposes.

Emma Stevens (G. Stevens).—A seedling Japanese reflexed, raised at Putney, with deep compact blooms, pure white, and handsome.

Stanstead White (J. Laing & Sons).—A Japanese variety with enormous pure white blooms, 10 inches in diameter, the florets very long, somewhat tubulated, less curving at the tip, after the Dragon style of bloom. A good show variety, represented in our illustration (fig 45, on page 379).

M. Charles Leboeuz (J. Laing & Sons).—A Japanese Anemone, a fine well developed bloom, with a well-raised centre and guard florets, citron yellow. A distinct colour. It was also certificated by the Royal Horticultural Society on the preceding day.

M. Pankoucke and Eynsford White (H. Cannell & Sons).—Both

these were certificated by the Royal Horticultural Society on the previous day, and were described last week.

Robert Cannell (H. Cannell & Sons).—A seedling incurved variety, with very large, deep blooms, and broad, well incurving florets. The colour is a deep brouzy red, showing in the outer florets a deep crimson upper surface like many of the Japanese. The plant was dwarf but strong. The colour is distinct, and the breadth of the florets would render the variety very conspicuous in a stand of incurved.

CHRYSANTHEMUM W. G. DROVER.

HAVING noticed this year that Chrysanthemums are developing unusually large blooms, perhaps the following may be of interest to the readers of your valuable paper. During the previous week an opportunity was afforded me of witnessing what appeared to be a grand bloom of the Japanese variety W. G. Drover. The specimen was a large and solid bloom, 11 inches in diameter and 6 $\frac{3}{4}$ inches in depth, after cupping, with a good full centre, medium to fine florets, devoid of coarseness, and of a brighter colour than those previously noticed. This bloom was only one of six, I am informed, of the same variety, each being of almost equal size and quality, and was grown by Mr. Trinder at Dogmersfield Park, who is known as a successful exhibitor of Chrysanthemums, and who will, no doubt, turn his fine blooms to good account in the forthcoming campaign. At a recent visit to the above gardens the plants were looking extremely well, the whole presenting fine healthy foliage, combined with moderately strong and solid wood. The early development of blooms this season appears to be general, consequently many fine examples will be sacrificed long before the principal shows commence.—VECTIS.

HARD CHRYSANTHEMUM BUDS.

I ENCLOSE for your inspection a specimen of an exceedingly hard undeveloped bud of a Chrysanthemum. I had several this season on different varieties, some partly opened, and produced a ben-and-chickens form of flower; others decayed and refused to open. The specimens sent were formed in July, and were at that time selected for suitable flower buds to produce well-formed flowers in September and October. The variety these were cut from is an American named Robert Craig. I trust they may be of interest to you.—ROBT. OWEN.

[The buds sent were nearly 2 inches in diameter, green, and quite hard, formed chiefly of short bracts and undeveloped florets.]

CHRYSANTHEMUMS AT FROYLE PARK.

AS I was privileged a few days ago to witness one of the grandest displays of Chrysanthemums I have ever had the pleasure of seeing, it occurred to me that a few notes would probably interest many lovers of the Chrysanthemum who, like myself, look weekly to the *Journal of Horticulture* for what is said on this favourite flower. Mr. Oliver, the proprietor of Froyle Park, is an ardent lover of horticulture, and through his liberality Mr. Coster, the gardener, has been enabled to make Chrysanthemums a speciality at Froyle Park, and this season he has excelled all his previous efforts in providing such a magnificent show at home as is seldom seen. About 600 plants are grown on the large bloom system, and I venture to say that healthier plants could not be found. Three to six flowers are allowed on a plant, which range from 3 to 5 or 6 feet in height, and the whole being very tastefully arranged in one long bank or group in the conservatory, the effect produced is very striking. All the best of the older varieties are represented, and the collection includes most of the later introductions of merit. Such varieties as L'Or du Japon, Avalanche, Mr. Garnar, Marsa, Sunflower, Garnet, M. Tarin, William Holmes, Moonlight, Stanstead White, Madame Laing, Sarah Owen, Madame de Sevin, Ralph Brocklebank, Mlle. Moulis, and George Daniels, I noticed as exceptionally fine. Enormous bush plants, with foliage to the rims of the pots, and with hundreds of flowers on a plant, of such varieties as Lady Selborne, Mrs. Cullingford and James Salter, arranged with fine plants of Bouvardias, &c., on the side stages, were a sight not often seen. Other plants are well done at Froyle Park, especially Violets, Primulas and Poinsettias. In one of the large plant houses I noticed a magnificent plant of the beautiful but seldom seen *Bignonia venusta*, commencing to flower very freely. Fruit and vegetables are also finely grown, but as my visit was to see the Chrysanthemums, I must defer the other objects of especial interest to a future occasion.—G. TRINDER, *Dogmersfield Park, Winchester.*

THE MORDEN PARK CHRYSANTHEMUMS.

AN annual pilgrimage to Morden Park (the residence of J. Wormald, Esq., one of the Vice-Presidents of the National Chrysanthemum Society), has for a number of years constituted one of the most agreeable events in the Chrysanthemum season programme. We are always certain to find there well-grown plants with capital blooms, and a genial unassuming guide and instructor. Mr. C. Gibson has proved himself to be one of the most skilful present day cultivators of the Chrysanthemum, and his record of successes at exhibitions is a long one, but he has also gained an enviable character as one of the best competitors to take a defeat in good spirit and without a murmur, though it must be admitted that he is not very often put to this test. Judging, too, by the condition of the plants and blooms, his temper is not likely to be very sorely tried this season, unless the damp weather prove more than usually injurious.

The plants are arranged in three lean-to vineries, and the majority have in consequence a light position, the blooms being raised nearly to

the glass in some cases. The collection comprises all the best of the older varieties in each section, and in addition the most reliable of recent novelties have been added, and their characters are being well developed. For instance, there are some wonderfully fine blooms of *Avalanche* which, in their present condition, would grace any exhibition stand; they are nearly 5 inches deep, and more in diameter, grand, solid examples, such as will scarcely be surpassed this year. Superb examples of *Stanstead Surprise*, *Ralph Brocklebank*, *Carew Underwood* (of high colour), *Sarah Owen* and *M. Bernard* are also noted, a late bud of the last named being remarkable for its intensely rich crimson hue. Of *Elsie*, two plants, each 7 feet high, are worthy remark, as they prove the value of this variety for decorative purposes, and so affording a supply of blooms for cutting. They have not been disbudded, and consequently bear between fifty and sixty medium sized and small flowers of a most delicate creamy tint, graceful in form, and admirably adapted for arranging with other flowers. *Criterion* is notable for the dark colour of its fine blooms, nearly as red as the sport, *Thomas Stephenson*, recently certificated. *Japonais*, *J. Délaux*, *Boule d'Or*, *Madame C. Audiguier*, *Bertier Rendatler*, *Belle Paule*, *La Triomphante*, *Amy Furze* (very fine), *M. Astorg*, *E. Molyneux*, and *Grandiflorum* are some of the most promising of the general stock, the last named not being nearly out as yet.

The incurved form an important portion of a showman's stock, in which the "old hands" take the greatest pride, and Mr. Gibson is no exception to the rule. He has a good collection of varieties, and the number of blooms is considerable, comprising of course plentiful fine examples of the "Queen family" so indispensable for "back rows" in stands. *Jeanne d'Arc* is well represented; of *Beatrice* the blooms are of exceptional depth, very clean and well developed; *Princess of Wales*, *Miss M. A. Haggas*, *Jardin des Plantes*, *Mrs. Shipman*, and *Mr. C. Gibson*, are also a few of many that are very promising. Japanese Anemones, large Anemones, and Pompons are also included, and help to make up a thoroughly representative collection, worth a long journey to see. This, at least, was the unanimous verdict of our little party of inspection, including an amiable lady amateur, an energetic Secretary, a much-travelled Judge, and the recorder of these notes. The animated Chrysanthemum discussion over the tea-table, and on the way homewards along the lampless roads of Morden, cannot, however, be reported now, as the "lady amateur" has promised to contribute something upon this matter.—RUSTICUS.

BRUNSWICK NURSERY, STOKE NEWINGTON.

IN the early days of Chrysanthemum-growing the above-named nursery contained one of the best collections of these favourite flowers to be found in this country, and throughout the district around Stoke Newington the Chrysanthemum found a congenial home. The rivalry that existed there among local growers resulted in the formation of the original Stoke Newington Chrysanthemum Society, from which has sprung the "National," that is doing so much to impart useful knowledge and encourage a taste for the Queen of Autumn Flowers. The Brunswick Nursery, from which many new varieties of Chrysanthemums found their way into commerce in former years, has in recent times been but little heard of, but under the management of Mr. J. R. Chard (well known in connection with dinner-table decorations and bouquet making) it seems likely again to rank creditably among those around London. Chrysanthemum-growing is made a specialty. Four thousand plants are this year grown in pots, the majority of them being in 6 and 7-inch ones, carrying from six to nine shoots, and a more healthy, vigorous, and handsome set of plants could scarcely be wished for, clothed as they are to the rim of the pots with thick leathery leaves deep green in colour. The varieties grown are selected for their suitability for market purposes; those bearing white or yellow flowers seem to be the most eagerly sought after, *Elaine* being one of the best. Nine hundred plants of that variety are grown, early or crown buds being taken from 200 plants. The remaining 700 are flowered from terminals. For market purposes it is not only necessary to grow the plants well, but a good deal of judgment is required to "catch" the market at the right time, hence the reason for growing some of each variety from early and some from late buds. *Avalanche* is expected to make a grand market sort; it has therefore been propagated as fast as possible throughout the summer, with the result that a fine stock of plants has been obtained, varying in height from 3 inches to as many feet. *Mlle. Lacroix* and *White Venus* are also grown in large quantities, and *La Vierge* and *Domination* are represented by hundreds of dwarf bushy plants. *St. Michael*, a bright yellow Pompon, is a great favourite, and is consequently largely grown. *William Holmes* has the reputation of being a good grower, as well as producing large flowers. Nearly a thousand plants of *Princess Teck* are grown to flower at Christmas, when they command a good price in the market. Fine stocks of *Madame Desgrange* and a few other early varieties were in flower a short time since. Several other varieties are largely grown, and when the majority of the plants are in flower the show of "mums" at Brunswick Nursery cannot fail to be a good one, for cleaner and more healthy plants could not be found, and although black fly has been unusually troublesome this season, no trace of it is seen here now. As soon as it appeared the plants were regularly syringed twice a week with an insecticide which has the advantage of destroying all kinds of insects that attack the Chrysanthemum without injuring either leaves or roots.

CHRYSANTHEMUMS ABOUT HAVANT.

THE cultivation of Chrysanthemums for large blooms has made wonderful progress during the last few years in the neighbourhood of

Havant, and it would be difficult to find a place of the same size around which so much interest is taken in the growth of this plant. As many as 5000 plants are annually grown here, although the population is only 3000 or 4000. The town is close to the water, and opposite Hayling Island, about seven miles north-east from Portsmouth, and nine miles west of Chichester, the situation in some parts of it being very low, a circumstance which is found most difficult for the growers to contend with in wet seasons in the matter of ripening the wood and in preserving the blooms from "damping." Much attention is paid to the growth of new varieties, the interest is so deep in this flower in that neighbourhood that any good new varieties are almost certain to be found there. As a rule the exhibitors confine themselves to the places on the south coast, and with success. I had lately an opportunity of paying a visit to the principal growers for the purpose of seeing what progress had been made during the present year, and as readers of the *Journal* may like to know a little of what is going on at this seasonable period, I will jot down a few notes which are made from memory.

EMSWORTH HOUSE,

The residence of Captain Boyd, has recently become noted for the growth of the Japanese varieties, to which special attention has been directed by the gardener, Mr. Woodfine, but it must not be thought that the Japanese are the only ones here grown; nearly all sections are cultivated, but these predominate here in point of quality. About 400 plants are grown annually; they are always characterised by good clean stems, which produces ample leafage, and as a rule are topped with large blooms, proving the desirability of a free growth in the production of large blooms. Prominent amongst them were *Florence Percy*, which showed its Endive-like appearance in true character, so fine were they. *Criterion* was here in splendid condition, as were also *Madame Blanche Pigny*, *Madame C. Audiguier*, *Thunberg*, *Jeanne Délaux*, *Ralph Brocklebank*, and many others, mention of which would serve no useful purpose, and which may have to be chronicled later on. Amongst the incurved were very fine blooms of *Princess of Wales*, *Jeanne d'Arc*, and *Lord Wolseley*. Extra fine specimens of *King of Crimson* and *Golden Christine* were to be seen in the reflexed section with many others.

LEIGH PARK.

On gently rising ground, one and a half mile from Havant, is situated the residence of Sir F. Fitzwygram, Bart. Mr. Penford, the gardener here, is well known as an ardent cultivator of "Mums," this year being no exception to the rule, as shown by his 600 plants, which are carrying splendid blooms. *Sunflower* is here very fine, showing its handsome drooping character to perfection. *Madame C. Audiguier*, *Edwin Molyneux*, *Val d'Andorre*, *Hamlet*, and *Charlie Sharman* are in good form, while amongst the incurved can be found capital blooms of *Refulgens*, *Nil Desperandum*, *Mrs. Heale*, *Princess of Wales*, and their two sports, *Miss M. A. Haggas* and *Violet Tomlin*, as well as capital examples of those perfectly formed varieties, *Mrs. G. Rundle*, *Mr. G. Glenny*, and *Mrs. Dixon*. Extra fine blooms of *Margouline*, *Sabine*, *Jeanne Marty*, and several others in the Japanese Anemone class were to be seen, the whole being likely to take prominent positions wherever they may be shown.

STANSTEAD PARK.

This has leaped into prominence most rapidly during the last few years as a place where fine Chrysanthemums can be seen. It is a pity their owner, E. P. Wilder, Esq., does not allow them to be seen upon the exhibition tables. Mr. Hoskins has this year grown about 800 plants, which are now developing substantial blooms. The best specimens of *Emperor of China* that it has ever been my lot to behold are here. Massive blooms they are, and the beautiful silvery white of the upper side of its florets is seldom seen as in this case. Capital blooms of *Prince Alfred*, *Lord Wolseley*, *The Queen*, *Criterion*, *Avalanche*, *F. Marrouch*, *J. Délaux*, *Soleil Levant*, *Mlle. Lacroix*, *Dr. Macary*, and many others are expanding.

Mr. J. Agate's nursery has recently sprung into prominence in Chrysanthemum world. A first-class span-roofed house has been built to accommodate the plants, and well they look in it, which contains 700 in all sections. Extra fine blooms are seen of *Avalanche*, *Edwin Molyneux*, *Etoile de Lyon*, *T. H. Spaulding*, a new American variety with broad white florets, and many other new sorts on trial, some of which promise well and others the reverse. Several new Anemone varieties look well, *M. Pankoucke*, *Nelson*, and *Sabine* being some of the best. Single varieties and Pompons are here largely favoured, and the incurved section is well represented by plants a little later in the development of their blooms.

THE OAKS, EMSWORTH.

Mrs. Smith resides here, and is evidently very fond of her garden, Chrysanthemums here being a specialty, as many as 400 or 500 being grown. Mr. Payne is a thorough enthusiast, and grows all the leading varieties as they appear in public. *Mlle. Blanche Pigny*, *Edwin Molyneux*, *Mrs. Falconer Jameson*, *Madame C. Audiguier*, *Prince Alfred*, *Refulgens* and *Lord Alcester* are in promising form.—VISITOR

CHRYSANTHEMUM STANSTEAD WHITE.

ENGLISH-RAISED seedling varieties are not too numerous, and really good additions are always welcome. Messrs. J. Laing & Sons of Forest Hill were fortunate enough to raise a batch of seedlings in 1885 which yielded several excellent novelties, including *Mrs. J. Wright* and some others that have already taken a high position amongst the best varieties. One of these seedlings was sent out in 1887 under the above

name, but it did not attract much attention until last year, when it was shown by several exhibitors in very good condition. This was particularly the case with some exhibited by Mr. F. Moor, Blerdon Hall

fine examples to the meeting of the Royal Horticultural Society's Floral Committee in the Drill Hall, Westminster, on October 22nd, but as only two blooms were shown (three being required by the rules of the Com-

FIG. 45.—JAPANESE CHRYSANTHEMUM, STANSTEAD WHITE (REDUCED).

Gardens, Bexley, at the Kent County Society's Show, and it was evident from the quality of these that the variety would soon become a favourite with competitors. This season Messrs. J. Laing & Sons sent equally

mittee) no certificate was awarded. On the following day it was shown at the National Chrysanthemum Society's Floral Committee meeting at the Westminster Aquarium, when it was at once granted a certificate.

The variety is described in our report of that meeting, and depicted in fig. 45, somewhat reduced, for it may be added that Mr. T. B. Haywood of Woodhatch Lodge, Reigate, has blooms 12 inches in diameter.

Mr. F. Moore writes respecting the variety as follows:—"The bloom of Stanstead White, exhibited by me last season at the Kent County Show, was greatly admired. I am much in favour of the variety, and no doubt it will be seen on many boards this season. I was pleased to see its raiser gained a certificate for it last week at the National. The plant is a dwarf grower with very broad dark green foliage, and is of good constitution, but liable to come early on the crown bud, which I prefer if procured before the middle of August. The bloom I exhibited was 10 inches wide and 5 inches deep, with broad spreading florets incurving towards the centre."

A SUBJECT FOR DISCUSSION AT THE CHRYSANTHEMUM CONFERENCE.

OFTEN when thinking over the question of the widely different constitutional characteristics of the Chrysanthemum the question has forced itself on my mind, Do the raisers of new varieties pay sufficient attention to the law of "heredity" as applied to constitutional suitability or adaptability to our climate? Every year new varieties are imported from France, and America may now be expected to contribute in this direction. The raisers may be honest in the belief that their selections are good ones, but do they ever consider that some, probably many, varieties of a constitutionally gross character may be amenable to cultivation in the sunnier climate of France or that of America, but when tried here have to succumb to "the law of the survival of the fittest?" If raisers could be induced to see the question from this standpoint, and so modify their practice in cross-fertilisation and seed-saving that seed parents (on one side at least) only should be used which English cultivators have proved to be reliable in our climate, this would prove to be a step in the right direction. In proof of this view of the question, the grumbling against raisers was both loud and deep last year, because the season was one of a low temperature with little sunshine.—T. GARNETT.

CHRYSANTHEMUM SHOWS.

WE have received schedules of the undermentioned Chrysanthemum Shows, and we shall be glad to insert the dates of any not included, if the secretaries will forward us schedules of their respective Societies.

Alverstoke and Gosport, Thursday and Friday, Oct. 31st and Nov. 1st.
Royal Horticultural Society, Centenary Conference and Exhibition at Chiswick, Nov. 5th and 6th.

Brighton and Hove, Sussex, Tuesday and Wednesday, Nov. 5th and 6th.
Finchley, Tuesday and Wednesday, Nov. 5th and 6th.
Market Harborough, Wednesday and Thursday, Nov. 6th and 7th.
Kent County, Wednesday and Thursday, Nov. 6th and 7th.
Portsmouth, Wednesday, Thursday, and Friday, Nov. 6th, 7th, and 8th.
Crystal Palace, Friday and Saturday, Nov. 8th and 9th.
Kettering and District, Saturday, Nov. 9th.
St. Neots, Monday, Nov. 11th.
Surrey (Peckham Public Hall), Monday and Tuesday, Nov. 11th and 12th.

Leeds Paxton, Tuesday, Nov. 12th.
National Chrysanthemum Society (Royal Aquarium), Tuesday and Wednesday Nov. 12th and 13th.

Kingston and Surbiton, Tuesday and Wednesday, Nov. 12th and 13th.
Wells, Tuesday and Wednesday, Nov. 12th and 13th.
Exmouth, Tuesday, Nov. 12th.
Torquay, Wednesday, Nov. 13th.
Croydon, Wednesday and Thursday, Nov. 13th and 14th.
Bournemouth, Wednesday and Thursday, Nov. 13th and 14th.
West Kent (Bexley Heath), Tuesday and Wednesday, Nov. 12th and 13th.
Teddington, Putney, Chiswick, Cranbrook, and Birkenhead, Thursday, Nov. 14th.

Leicester, Friday, Nov. 15th.
Eccles, Friday, Nov. 15th.
Cheshunt, Friday, Nov. 15th.
Bolton, Friday and Saturday, Nov. 15th and 16th.
Twickenham, Tuesday and Wednesday, Nov. 19th and 20th.
Liverpool, Tuesday and Wednesday, Nov. 19th and 20th.
Cardiff, Tuesday and Wednesday, Nov. 19th and 20th.
Rugby, Wednesday and Thursday, Nov. 20th and 21st.
Birmingham, Wednesday and Thursday, Nov. 20th and 21st.
Hull (National Society's Provincial Show), Thursday and Friday, Nov. 21st and 22nd.
Chorley, Friday and Saturday, Nov. 22nd and 23rd.
Stockport, Friday and Saturday, Nov. 22nd and 23rd.

CHRYSANTHEMUM SHOW AT YORK.

MR. J. LAZENBY, 13, Feasegate, York, writes: "The Committee purpose having a stall at the above Show on November 20th, 21st, and 22nd, for the sale of flowers, fruit, and cut Ferns. The proceeds to be devoted to the Gardeners' Orphan Fund. They respectfully invite contributions for that object, which would be thankfully received. Please forward on any of the above dates."

CLIFTON HALL, NOTTINGHAM.

If anyone wishes to become truly appreciative of the beauty of Clifton and its neighbourhood he must make up his mind to spend a

whole day there. Each rocky height and each glade has a distinct charm. Approached on the one hand by its renowned grove, and near the ribbling waters of the River Trent, this little village stands unrivalled. The Hall gardens at the time of our visit were in their prime, although the third week in September had already passed. The prodigal display of bloom was no less delightful than surprising. The foliage of the grand trees was darker in tone, but they showed little or no signs of decay. The turf was close and smooth, but there were then no dead leaves to sully it, and only on one or two trees was there the faintest flush of pale gold. The whole place is remarkable for its quiet beauty and suggestiveness. The Hall itself is a grand old pile, with the silver stream, upwards of 100 feet below, which daintily threads its way through a most lovely valley.

The terrace flower garden is somewhat of semicircular form, surrounded by a broad terrace walk. On the garden side of this terrace is a steep bank of velvety turf, and on the other side extensive herbaceous borders. The beds are all geometrical in style, and are laid out on a soft and excellent carpet of turf. Spacious and well kept gravel walks intersect and surround this garden, the centre of which contains an ornamental fountain and basin, whilst by means of handsome stone steps an easy communication is maintained between it and the terrace. Some of the largest beds were filled with sub-tropical plants edged with dwarfier plants, and these do good service in the way of softening the brilliant effect produced by numerous carpet beds and others massed with Pelargoniums, Calceolarias, and ordinary bedding plants. The carpet bedding is exquisite, and the patterns tasteful and well defined. The beautiful Fern-like variegated *Polemonium coeruleum* forms an important constituent in the composition, as do likewise the various *Alternantheras*, compact growing *Lobelias*, *Coleuses*, *Iresines*, *Centaureas*, *Echeverias*, *Sedums*, and others too numerous to mention. Ascending the terrace steps, we were at once struck with the beauty of the scene. The great conservatory or winter garden was before us, and a full view of the flower garden was obtained. At this point the busy town of Nottingham may be seen in the distance, with its historic castle standing upon its time-worn rock. A long row of venerable Yews arrested our attention. Here have they stood for hundreds of years steadily growing and spreading, till they have become venerable and claim our reverence. Near here are three large beds (star-shaped), which were chiefly devoted to *Clematises* Jackmani and Lady Bovill. They were very effective, and quite in harmony with the surroundings. In isolated positions on the lawn are pretty examples of *Araucaria*, *Wellingtonia*, *Cupressus*, and other choice shrubs, whilst amongst deciduous trees *Acer Negundo* is effectively used. Near also is a quaint old ruin, known as the chapel, which is covered with luxuriant Ivy, hiding the injuries inflicted by man, and shielding it as far as in its power from time the destroyer.

Passing along, the small herbaceous garden is reached. A bed of the beautiful Windflower, *Anemone japonica alba*, crowded with delicate snow white flowers, and from the centre of the bed sprang the brilliant scarlet Cactus *Dahlia Juarezi*. There are many objects of interest in this part of the ground, but space will not permit of their enumeration. But it is impossible to look without admiration on the little scene that lies before us—rocks and dells, woods and groves, sunshine and shade, the mossy rock surfaces half clothed with varied vegetation, and presenting the utmost richness of colour. The remnants of several old Larch are richly mantled with Ivy, and their tangled mass remains as it were a memoir of the past.

The kitchen gardens were reached at last, and we were conducted by the gardener, Mr. Anderson, to the vineries, of which there are two, and grand examples of good culture did we find. Golden Queen we have never seen in better condition. Its constitution seems robust, the leaves are of great substance, and we could not help noticing the strikingly handsome appearance of the bunches. The flavour is superior, and altogether its character is irreproachable. Mrs. Pince is well grown at Clifton, many of the bunches being perfect examples. Some massive bunches of Black Hamburgh, Alicante, Muscat of Alexandria, Gros Guillaume and Lady Downe's were very noticeable, and bear every indication of good culture. The houses are span-roofed with ends facing south; they are built with arched foundations, the Vines are planted inside the houses, and are grown upon the single-rod principle. There are numerous other houses near here devoted to Peaches, Roses, and other plants, but the principal plant houses are situated in another part of the kitchen garden. A small but choice collection of Orchids is grown, some fine *Calanthes* being worthy of notice, large pseudo-hulbs just throwing up very strong flower spikes. We also noticed several fine healthy pieces of *Cypripedium Lawrenceanum*, *Cypripedium Spicerianum*, and *Cypripedium caudatum*.

In one of the plant stoves is a huge *Allamanda Hendersoni* carrying hundreds of highly coloured flowers. Table plants are well grown, and a large supply is needed for the embellishment of the Hall. Clifton has long been noted for its collection of Pears, and many of the wall trees are heavily laden with fruit of superior quality, Pitmaston Duchess, Marie Louise, and Beurré Diel being especially worthy of mention. Apples are a heavy crop, Blenheim Pippin, Spencer's Favourite, and Pike's Pearmain carrying heavy crops.

The large ornamental conservatory near the Hall contains a valuable and highly interesting collection of plants. This noble structure runs along the entire front of the flower garden. The interior of the roof is profusely draped with creepers, the beautiful *Tacsonia Van Volxemi* hanging in graceful festoons, and the back wall is richly clothed with the lovely *Asparagus plumosus nanus*, which has already attained a height of over 20 feet. Several of its growths have taken possession

of the chains which suspend the ornamental baskets from the roof. Another interesting plant of great beauty which has attained a height of more than 20 feet is *Ruscus androgynus*, which Mr. Anderson uses very freely in a cut state for decorative purposes. Several wire arches span the principal path, and nothing could be more lovely than the way in which they are utilised. The pretty *Abutilon vexillarium variegatum*, with its mottled or marbled foliage, hangs gracefully from one, whilst another is richly wreathed with the sweet-scented *Solanum jasminoides*, and several others with *Asparagus plumosus*. Another striking feature is to be found in a noble example of *Brugmansia suaveolens*, laden with large, sweetly-scented flowers. The centre bed is devoted to rare Palms, Musas, Dracenas, Camellias, Rhododendrons, and other plants, whilst upon the front stage a display of *Celosias*, *Gloxinias*, Tuberous *Begonias*, *Fuchsias*, and a host of other plants contribute to a very effective display. There is a fountain in the centre of this house which when in full play imparts a coolness and freshness to the whole place. The respected owner, Henry Markham Clifton, Esq., J.P., is to be congratulated upon its possession, and the gardener, Mr. Anderson, upon its excellent keeping.—J. H. WALKER.

EVENTS OF THE WEEK.—A busy season is now commencing, and during the next fortnight or three weeks there will be abundant to occupy the time and attention of those in any way concerned with *Chrysanthemums*. To-night (Thursday), at eight o'clock, a concert will be held in the Vestry Hall, Chiswick, in aid of the Gardeners' Orphan Fund. On Tuesday, November 5th, the Royal Horticultural Society's *Chrysanthemum* Centenary Exhibition and Conference will be opened in the Chiswick Gardens. On the same days Shows will be held at Brighton (Sussex), which is expected to be unusually good this year, at Brixton, and Finchley. Upon the following day (Wednesday, November 6th) Shows will be opened at Portsmouth and by the Kent County Society, both of which are likely to possess considerable interest and importance.

— WE record with much regret the death of MR. WILLIAM GODWIN of Kiln Bank, Market Drayton, which occurred on October 17th last. Mr. Godwin was in his eighty-ninth year, and had been the proprietor of Kiln Bank Nurseries for seventy years. He has always taken a great interest in the scientific and literary departments of the pursuit, and was a close reader of the *Journal of Horticulture*. He was a great fruit fancier as well as a naturalist and sportsman.

— **FRUITERERS AND THE LORD MAYOR.**—The Masters, Wardens, and Court of the Fruiterers' Company recently waited upon the Lord Mayor at the Mansion House, and admitted him to the freedom and livery of their Guild and to membership in their Court, in recognition of the laudable efforts he had initiated for the improvement of fruit culture throughout the country. The Master (Mr. R. S. Mason) mentioned that in the long history of the Guild there was no previous instance of a person being admitted in one day to the freedom, livery, and Court of the Company, and they intended the Lord Mayor's admission as a personal compliment to him in grateful appreciation of his great interest in fruit culture. The Lord Mayor thanked the Company for the honour they had paid him, and said it was his firm belief that fruit farming and the cultivation of orchards might be profitably revived throughout the country, and that instead of importing so much of our fruit from foreign countries it might be grown here with profit to the farmer and with advantage to the public.

— **NATIONAL AURICULA AND CARNATION AND PICOTEE SOCIETIES (SOUTHERN SECTION).**—The name of Baron Schröder should be added to the Patrons of the above Societies, and the Treasurer's balance in favour of the Carnation Society is £4 17s. 11d., and not £4 7s. 5d., as stated by the Treasurer at the recent annual meeting.

— **TRADE ANNOUNCEMENT.**—We learn that after November 1st, Mr. B. S. Williams of Upper Holloway will trade as Messrs. B. S. Williams and Son, Mr. H. Williams having formally entered the firm.

— **GARDENING APPOINTMENTS.**—Mr. Charles Foster, late foreman in the gardens of A. H. Smee, Esq., Hackbridge Grange, Carshalton, under Mr. G. W. Cummins, has been appointed gardener to E. P. Martin, Esq., Dowlais House, Dowlais, Glamorganshire. Mr. M. E. Mills,

recently second gardener to Baroness Heath, has been appointed head gardener at Coombe House, Croydon.

— READERS of the Journal will be pleased to hear that the WARE AND DISTRICT HORTICULTURAL MUTUAL IMPROVEMENT SOCIETY has been successfully established. It will be conducted by rules similar to those of the Chiswick Society. Stanley Gray, Esq., is President, and Mr. J. B. Riding Hon. Sec.

— **PRESTON AND FULWOOD HORTICULTURAL SOCIETY.**—The twenty-fifth monthly reading (third of the present season) in connection with the above Society will be given in the large room of the Castle Hotel, Market Place, Preston, on Saturday evening, November 2nd, when Mr. Councillor Jos. Harding will read his paper on "Landscape Gardening in its Relation to Villas, Public Parks, and Cemeteries." Chair to be taken at 7.30 by the President.

— MR. J. HIAM offers a timely hint on BULLFINCHES. He says from now to Christmas is a suitable time to catch and keep these birds, but does not tell us how. I have not been a reader of the Journal for so many years as ten. I should be glad if he would give some particulars now as to their capture and keeping, as they are a great pest, they and linnets, to gardeners and cottagers in this district. His manner of dealing with rats I consider first class and practical.—M. DAVIDSON, Bolton.

CHRYSANTHEMUM MRS. ALPHEUS HARDY.—This American variety which has attracted so much attention, is now flowering in Mr. T. S. Ware's nursery, Tottenham, and shows its peculiar character remarkably well.

— **MEDALS FOR INDUSTRY.**—Mr. J. Wright's idea, page 308, respecting awarding medals, &c., to meritorious horticulturists other than "showmen" has long been in operation in connection with what are known in the gardening world as the "Neil" prizes. I cannot lay my hands on the particulars of them at this moment, but I think they amount to £60 every three years, and this sum has been awarded in several instances to gentlemen rarely heard of at shows.

— **CLASS EXHIBITS.**—I am very partial to these, as they give one the opportunity of judging collectively, and making selections without having to trust to descriptions. The collections of Apples shown at Edinburgh on September 11th, and before the Royal Horticultural Society on October 8th by Messrs. Veitch, are typical of what I mean, and all who wish to produce striking and instructive displays should follow this system.—PRACTITIONER.

— **IMPATIENS HAWKERI.**—*Impatiens SULTANI* is a familiar plant to many, but *I. Hawkeri* is a finer plant, and when properly grown gives a profusion of good sized rich rosy carmine flowers. It can be raised from cuttings in a gentle heat at any time after February, but over-potting and over-feeding must be avoided. Still, when the pots are full of roots a little liquid manure may be used. For compost use good turfy loam, leaf soil, and sand, and do not expose the plants to much sunlight, or the young flower buds get cramped. Ordinary greenhouse culture suits it through the summer, and it is everybody's plant.—D. S. H.

— **REFERRING to query in last issue by "J. L." as to the BEST PINK BEDDING ZONAL PELARGONIUM, Mrs. Turner, which he mentions approvingly, is one of the finest bedders we ever sent out, but is losing favour at the present time, as the ladies have set their faces dead against any flower which has any suspicion of magenta or mauve in it. The best of the rosy pinks which are free from the objectionable shade is Mrs. A. Miles, but I think this and all the older varieties will be put in the background by the sport obtained by Mr. Crocker, which was described in your columns some few weeks back.**—CHAS. E. PEARSON, Chilwell Nurseries, Notts.

— **PEACHES.**—Will those that have grown Waterloo and Alexander Peach kindly say if these are synonyms, or whether there is any difference in time of ripening, as we intended adding Waterloo to our house, where Alexander is already grown. Thames Bank Peach out of doors is very fine here; the most showy yellow Peach we have. It has been greatly admired for colour and flavour. We think the pinch of dark sulphur in soft water (copied from *Journal of Horticulture*) has cured our mildewed Roses indoors, where air must be given, also on Vines and *Chrysanthemums*. It has proved simple but effective, and we intend trying it on Peas another year. We believe it will cure cases where mildew has hitherto been the master.—H. GALTON, Gardener to Sir Chas. Frederick, Bart.

— THE GARDENERS' ORPHAN FUND.—The usual meeting of the Committee took place at the Caledonian Hotel, Adelphi, on October 25th, Mr. George Deal in the chair, there being a good attendance of members. The minutes of the last meeting having been read, the Hon. Secretary announced there was a balance at the bank of £424 17s. 10d. Some receipts from special sources were announced, including £6 10s. from Mr. W. Wildsmith, Heekfield Gardens, on the occasion of opening the gardens; £2 12s. from Mr. W. H. Divers, Ketton Hall, on the same occasion, but the day was wet; £4, the proceeds of a concert at Swallowfield, from Mr. C. W. Allen; and £1 from Mr. J. Wallis, Keele Hall Gardens, a portion of the offertory on the occasion of the harvest festival. The following donations were announced:—Mr. J. Broome, Llandudno, £5; Messrs. Oakshott & Mil'ard, Reading, £2 2s.; Mr. T. B. Potter, M.P., £1; and money boxes as follows: Mr. G. Milford, Egerton Lodge, Melton Mowbray, £3; Wakefield Paxton Society, £2 10s.; Mr. J. Miles, Southampton, 21s.; Mr. R. Greenford, Priory Gardens, Warwick, £2 1s. 3d.; Mr. C. Sutton, Chevening Park Gardens, 12s.; Royal Horticultural Gardens, Chiswick, 5s. 3d.; Mr. W. A. Green, Wolverhampton, 3s. 7d. The quarterly allowance to children upon the Fund, £61 15s., was ordered to be paid, and a sum of £300 placed on deposit at the bank. It was announced that the sum of £3025 19s. 10d. has been invested. The proceedings closed with a vote of thanks to the Chairman.

— A FINE CAMELLIA.—There is a wonderful specimen of a double white Camellia at The Henburys, Moseley, Birmingham, the residence of G. F. Lyndon, Esq. This tree has been at The Henburys fifty years, and was supposed to be from fifteen to twenty years old when placed there. It is growing in a box 6 feet square and 3 feet deep, and stands on a revolving plate, so that the tree can be readily moved round to face the front of the conservatory. The tree is 18 feet high, and was 24 feet high, but getting too tall for the house 6 feet of the top was cut out some few years since. It is 18 feet through, and is clothed with free healthy growth to the bottom. It is in the best of health, with a profusion of large dark green foliage, and has at least 3000 buds left upon it, a very large number having been taken off. The tree is symmetrical in growth, and I doubt if a finer specimen exists.—ON-LOOKER.

— THE fortnightly meeting of the READING AND DISTRICT GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION was held at the British Workman on Monday evening (October 28th), when a good number of members assembled to hear a paper entitled, "How to Prolong the Season for Some of the Most Popular Vegetables," by Mr. Chas. Hott of Wokefield Park. Mr. Wm. Lees presided. The vegetables dealt with were Peas and French Beans, Seakale, Asparagus, Cauliflower, Horn Carrots, Globe Artichokes, and Vegetable Marrows. Some good French Beans and Improved Ne Plus Ultra Peas were exhibited, gathered on Monday from the open ground, which proved that the season for these vegetables may be prolonged very considerably by protection. A discussion followed, at the conclusion of which Mr. Hott was heartily thanked for his able paper. Mr. J. Woolford exhibited some good pans of *Pleione lagenaria* and *P. maculata* from Mr. Alfred Palmer's collection. These, interspersed with Maidenhair Ferns, had a very pretty effect. A vote of thanks was accorded.

— FLOWERS IN KIRKCUDBRIGHTSHIRE.—The following are in flower to-day, 28th October, in my small garden close to the Solway:—Perennials: Dahlias, Phloxes, Pyrethrums, Chrysanthemums, Gaillardias, Anemones, Violas, Pentstemons, Aubrietias, *Alyssum saxatile compactum*, *Arabis alba*, *Hypericum reptans*, *Linaria anticaria*, *L. alpina*, *Sedum spectabile*, *Geum coccineum* fl. pl., Asters, *Crocus longiflorus*, *C. suaveolens*, Roses, *Primula cashmeriana*, *Papaver nudicaule*, *Campanula pyramidalis*, *C. carpatia*, *C. persicifolia alba*, *Armeria plantaginea*, *Onosma taurica*, *Myosotis*, *Gladioli*, *Oenothera taraxacifolia alba*, *Polyanthus*, Primrose, double Lilac, Oxlip, *Rudbeckia Newmanni*, *Potentilla nepalensis*, *Lithospermum prostratum*, *Hieracium aurantiacum*, *Antirrhinum*, *Agrostemma coronaria alba*, *Erica vagans alba*, *Iberis stylosa*, *Orobis*, Hollyhoek, *Fuchsias*, *Jasminum nudiflorum*. Annuals: *Chrysanthemum coronarium*, *Calendulas*, *Coreopsis*, *Nemesia compacta*, *Saponaria calabrica*, *Tropaeolum majus*, French Marigolds, Mignonette, *Alyssum maritimum*, and *Ionopsidium acaule*. The Colehums are out of bloom, having flowered unusually early, *C. variegatum* being the first, opening August 18th, and *C. autumnale* opening August 20th. *Crocus Boryi* and *ochroleucus* will be in flower in a day or two, and *C. Imperati*, *C. Sieteri*, and *C. biflorus* are all above ground.—S. ARNOTT.

— COMMERCIAL BOTANY.—It would be impossible to form any correct idea of what has been attained in the knowledge of plants, useful or otherwise, without referring to the results of the principal expeditions which have left our shores for different parts of the world during the present century, such, for instance, as Ross's Antarctic Expedition, which resulted in "The Botany of the Antarctic Voyage of H.M. Ships Erebus and Terror, in the years 1839 to 1843," by Dr. (now Sir) J. D. Hooker; or Captain Kellet's voyage of the Herald, after which appeared "The Botany of H.M.S. Herald during the years 1845 to 1851," by Berthold Seemann; or in still later times Captain Nares' Challenger Expedition from 1873 to 1876, the botany of which occupies two large volumes, principally the work of Mr. W. B. Hemsley, F.R.S. Not that these expeditions have resulted directly in the introduction of any one useful plant either for general culture or commerce, but they have been instrumental in imparting a knowledge of the resources of the several countries visited, and in this way have awakened an interest in them. Important, indeed, as these expeditions have been in elucidating the botany of the world, still more so has been the formation of the several museums in the principal centres of the United Kingdom for the especial purpose of developing the economic resources of the vegetable, animal, and mineral kingdoms, such as the food collection, first at South Kensington in 1857, and later at Bethnal Green, the Industrial Museum at Edinburgh, and the Museums of Economic Botany at Kew, founded in 1847. These, together with the Royal Botanic Society of London, founded in 1839, and the Pharmaceutical Society of Great Britain, founded in 1841, must always be considered the centres from which knowledge on these points has flowed, and continues to flow. Nor must we forget the several International Exhibitions since 1851, where the vegetable resources of the globe, especially of our colonies, have been prominently brought to the notice of millions of people. Then, in connection with these museums and exhibitions is the literature which emanates from them, such as the handbooks and guides, in which, though published mostly for a few pence, a mass of valuable information is given. We cannot leave this part of the subject without a word of high commendation on the handbooks and catalogues issued by the several colonies at the Colonial and Indian Exhibition of 1886, which should be in the library of everyone interested in economic botany.—(*Cassell's "New Popular Educator."*)

UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.

THE annual dinner of the above Society was held at the Cannon Street Hotel on Wednesday, October 23rd, at 6 P.M., N. N. Sherwood, Esq., presiding. There was an excellent attendance of members and friends, 140 being present, and the Chairman was supported by Mr. H. J. Veitch, Mr. W. Nutting, Mr. Cavendish, Mr. J. Laing, Mr. W. Paul, Mr. T. S. Ware, Mr. G. Deal, and Mr. E. R. Cutler. Amongst others present were Messrs. F. Berry, R. J. Chard, N. Cole, W. Cummins, J. George, J. Hudson, S. Mortimer, W. Rapley, S. Summers, E. G. Wheeler, G. Wheeler, and J. Wheeler, A. F. Barron, W. G. Head, C. W. Goldsmith, G. Stevens, E. Butts, Norman Davis, W. Thompson, G. Gordon, L. Castle, B. Wynne, and the Secretary, W. Collins, 9, Martindale Road, Balham. The programme was a long one, perhaps somewhat too long, and the speeches, with few exceptions, were not correspondingly brief, but what may be termed the more serious business of the meeting was most pleasantly varied by an admirable selection of songs well rendered by Miss Mary Belval and her friends.

The customary loyal toasts were duly honoured, and then the Chairman proceeded to the toast of the evening, "The Prosperity of the United Horticultural Benefit and Provident Society," and in the course of his speech he reviewed the origin and history of the Society, the scope of its work, and its constitution, referring in terms of the highest commendation to the respective funds and the rules guiding their application. He mentioned incidentally that as a result of the good working of the Institution it was a notable fact that some members had £50 or £60 standing to their credit, that there are at the present time no sick members on the list, and the total number of paying members is now over 300. The Society was doing, he considered, a great amount of good in encouraging men to make some provision for rainy days, a duty to which everyone should give attention early in life. Mr. Sherwood pointed out the respective advantages of the Benefit and Benevolent funds, but remarked that he thought another was needed—namely, "a convalescent fund," which would make some provision for gardeners who were not in a sufficiently good state of health to perform their duties for a time, and yet not absolutely ill, or when they were recovering from an illness. It was simply an idea of his own, and if the Committee thought it desirable to establish anything of the kind he would be happy to contribute 25 guineas as a start. He also stated that Baron Schröder had offered a 5 guinea donation to the Society, and an annual subscription of 1 guinea, both statements being received with loud applause.

Mr. N. Cole responded to this toast, and Mr. H. J. Veitch followed

with "The Health of the Chairman," proposed in his usual felicitous manner, and Mr. Sherwood acknowledged the compliments in fitting terms, mentioning that Mr. E. R. Cutler, the veteran Secretary of the Gardeners' Royal Benevolent Institution, had been requested to take the chair next year.

Mr. Hudson proposed "The Honorary and Life Members," to which Mr. William Paul replied in an interesting discourse upon the difficulties of gardeners and the progress of recent years.

Mr. R. Dean performed the task of thanking the Trustees, duly acknowledged by Mr. J. Wheeler. "The Health of the Secretary," Mr. W. Collins, was honoured in the same way, and with various other toasts, including the hearty thanks of all present to those who had contributed flowers and fruit so liberally for the decoration of the table, an agreeable evening was brought to a close. It may be added that the tables were most tastefully decorated under the supervision of Mr. Chard, and some elegant bouquets were presented to the lady vocalists and Mrs. Cutler.

CLIMBING NIPHETOS.

I WAS told the other day that this variety is capable under good treatment of making shoots 16 feet or more in length during the season, and that it will break from the eyes along such shoots and flower freely. Is this its character? Is it a free bloomer? On what stock does it appear to do best? The experience of those who have grown it during the past season, with some details of its behaviour, would prove invaluable to many readers besides myself.

ROSES FOR CHRISTMAS.

For flowering at Christmas I have not yet been able to select a variety that will supplant either Safrano or Isabella Sprunt. They are both profuse flowerers, good growers, and bear early forcing without much injury. Plants intended for this purpose should have been pruned and in a liberally ventilated position; indeed, if exposed to the recent frosts all the better. By the time this appears in print the house or pit in which they are to be forced should be closed. If the Roses are planted out in a permanent bed the soil should be top-dressed with rich material and then thoroughly soaked with tepid water. Keep the ventilators closed and maintain a night temperature of 50°. If the plants are grown in pots keep them in a similar temperature until they display signs of moving. In this stage they can be transferred to a house or pit in which a gentle hotbed has been formed of Oak or Beech leaves. The gentle heat from these will be ample to excite them into growth. If aphides have existed upon the plants, the house in which they are grown or to be forced should be thoroughly fumigated with tobacco smoke. All traces of these insects should be eradicated before the plants start into growth. The tender foliage of Roses is easily injured by tobacco smoke; in fact, the quantity necessary to destroy green fly will frequently injure their tender foliage during winter and early spring.

ROSES FOR NOVEMBER AND DECEMBER.

As a rule useful flowers for cutting during these months are not so plentiful as during the early months of the year. All outside flowers are over by the end of October, and without special provision there is a break during the two following months. The old *Souvenir de la Malmaison* is suitable for flowering from the middle of October until nearly the end of the following month. For this purpose the plants should be grown in pots outside and housed early in October. It is necessary to give them a temperature of 50° to 55°, in which they open their flowers freely. Naturally this variety flowers freely in autumn, and can with a little care be as well grown in pots for this purpose as when planted in beds and borders outside. Plants on their own roots should be potted at the present time, and given a little more root room than would be necessary for H.P.'s, or the plants can be placed into larger pots towards the end of June or early in July. If unduly confined at their roots they discontinue growing and fail to start freely from the base. One good shoot from the bottom will produce a dozen or more blooms. It likes a lighter soil than is good for H.P.'s; in fact, a compost that is suitable for Tea varieties will suit it well. It does well in good loam, moderately light, to which is added one-third of leaf mould and one-seventh of decayed manure. When plants are grown specially for autumn flowering they must have through spring and summer as nearly natural treatment as possible. Protection in frames from severe frost only is needed, and if pruned towards the end of March and plunged outside they will flower profusely in autumn. In pruning cut them hard back. The first blooms may not be so plentiful as if they were not pruned hard, but it induces them to push strongly from the base, and considerably more flowers in autumn will result.

To follow this variety it would be impossible to select two more suitable than those advised for flowering at Christmas. Young plants of *Niphetos* raised in spring or second season plants will flower freely enough during November if they are given liberal root room and

encouraged to grow. As buds only can be expected during the declining months of the year it is questionable if for quantity *Safrano* and *Isabella Sprunt* can be surpassed. For small glasses, buttonholes, and sprays these are very suitable. They root freely, and for this purpose plants struck in spring and grown on in pits throughout the summer, and then planted out in Cucumber or Melon houses towards the end of September are suitable, and will yield quantities of their choice delicate flower buds. Old Cucumber and Melon soil will do for them, with the addition of one-third leaf soil. They should be planted thickly together, and encouraged to grow by maintaining a gentle warmth about them from the time the night temperature shows signs of falling below 50°.

MARECHAL NIEL IN WARM VERSUS COOL HOUSES.

For a long time we were under the impression that the stock upon which this variety was grown influenced the colour of the blooms in no small degree; but when the colour of the flowers differed widely from those of plants on their own roots we were compelled to modify this opinion, and look to other causes than the stock. The position in which the plants are grown and the temperature of the house has more to do with the colour of the flowers than the stock. Plants that are grown almost naturally in the greenhouse are much paler in colour, as a rule, than those that are grown in a warm structure. For the production of highly coloured flowers the plants should be assisted by gentle heat to make and complete their growth as early in the season as possible, so that the wood will become hard and firm. Wood of moderate strength that is brown and thoroughly matured will produce flowers of a large size and good colour, while strong unripened wood will produce those of the very palest colour. Plants that were cut back after flowering and given greenhouse treatment only are still growing vigorously. Some of the shoots are strong, soft, and unripened. Although some of them are 20 feet or more in length they have not that firmness about them that one would desire for yielding the finest type of blooms. Plants in various gardens that have come under my notice vary largely, both in the colour and size of their blooms; but I have invariably noticed that those which have a somewhat stunted appearance, and make firm, short-jointed, hard wood of moderate strength yield large well-coloured flowers. These plants are, as a rule, liberally supplied with liquid manure, and very rarely die from canker. A plant on its own roots in a cool house, a portion of the growth being trained near the top on the back wall of a vinery, is a striking illustration of what warmth will do towards ripening the wood and influencing the size and colour of the flowers. The flowers produced from that portion in the cool house are pale in colour and small in comparison to those from the portion in the vinery. Experience and observation have led me to the conclusion that if *Maréchal Niel* were assisted by warmth to make an early growth and ripen it thoroughly the results would be more satisfactory in many gardens than they are at the present time. —NORTHERNER.

AN INCONSOLABLE JACKDAW.

WE have a handsome and intelligent Jackdaw. It was taken from the nest last spring and given to my youngest girl, who is immediately in touch with living Nature. When absent during school terms the Jackdaw is cared for by the cook, a young woman of gentle and just disposition, to whom the bird attached itself strongly. Last week she left to be married. She had grown so fond of the jackdaw meantime that she would willingly have taken him away with her, but then its own young mistress mentioned her pet in every letter, imploring that he might be kept. Jack is not so popular generally as with my daughter and cook. On the morning of the day (last Monday) that cook left, after she had gone I went into my bedroom on the ground floor with broad stone slabs and round bay window; there sat Jack. I spoke to him, no reply. He does say a great deal usually in jackdaw croaks, and even tells us "Jack talks," "Come along," &c., but he made neither sign nor sound, and in a minute or two flew on to a low close-clipped Yew hedge, where in happier days he used to saunter about in the sun. Evidently he could not bear to be sympathised with, and soon disappeared altogether, getting into some higher shelter in another part of the garden lonely and silent. All day he remained there, resisting every attempt to have him down, and he spent the night out of doors in a still higher tree. So for twenty-four hours he remained without food.

Next morning he was got down, put into his wicker, and well fed, but imprisoned for a day or two. Then his wings were cut, he was released, his bath was prepared for him as usual. He began to seem more himself, talks a little, and follows me as he always does closely about the garden, with all a jackdaw's quaint curiosity. —A. M. B.

THE SOURCES OF THE NITROGEN OF VEGETATION.

No problem relating to the nutrition of plants has given rise to so much discussion as that of the source of their nitrogen and the methods of its assimilation. It is obviously both a matter of the highest scientific interest, and also, owing to the high price of combined nitrogen in manures and the comparative ease with which it is washed out of the soil in the form of nitrates, one of great practical importance to the agriculturist and the community.

Ever since the discovery of the composition of atmospheric air by Priestley, Scheele, and Lavoisier, the question as to whether plants were able to absorb and utilise free nitrogen has attracted much attention.

At the end of the last century, or beginning of this, Ingenhousz, Sennebler, Woodhouse, and De Saussure became interested in the subject. Boussingault commenced his experiments in 1837; Ville, whose results conflicted with those of Boussingault, in 1849; and, shortly after, this last named investigator started a new series of experiments which confirmed his former conclusions that plants, under the conditions of the experiment, were not able to assimilate free nitrogen.

In 1857 experiments on the assimilation of free nitrogen by plants were started at Rothamsted; and in 1861 was published in the Philosophical Transactions, the classical memoir of Lawes, Gilbert, and Pugh, on this subject. In this earlier paper a brief history and summary of the results of other experimenters is given, and then the recent results obtained at Rothamsted. The conclusions arrived at were identical with those of Boussingault, that there is no evidence that plants assimilate nitrogen. Still the authors allowed that there were some difficulties with regard to the supply of nitrogen to leguminous plants, which assimilate from some source or another much more nitrogen than gramineous plants under similar conditions of supply of combined nitrogen. It was admitted that, "if it be established that the processes of vegetation do not bring free nitrogen into combustion, it still remains not very obvious to what actions a large proportion of the existing combined nitrogen may be attributed."

These views, that plants were unable to assimilate free nitrogen, were widely and generally held for many years, though there have always been some dissentients. In the meantime, however, the indefatigable investigators of Rothamsted have not been resting in the matter, but have added much to our exact knowledge of the supplies of combined nitrogen to the soil from the air, on the amount and nature of the combined nitrogen in soils and in crops, on the processes of nitrification in soils, and the amount of nitrogen removed from soils in crops and in drainage. During the last few years the main question as to the availability of atmospheric nitrogen to plants has taken a somewhat different aspect: it is now often suggested that though the higher plants are unable to directly take up free nitrogen, yet indirectly it is brought under contribution in some way; the ways most generally favoured being either under the influence of electricity of low tension, or of microbes or some low forms of organisms; and by such means it is thought that nitrogen is brought into a form in which it is useful to the higher plants.

In Sir J. B. Lawes and Dr. Gilbert's new memoir ["On the Present Position of the Question of the Sources of the Nitrogen of Vegetation, with some New Results, and Preliminary Notice of New Lines of Investigation." By Sir J. B. Lawes and Prof. J. H. Gilbert. Phil. Trans. 1889., clxxx. B. pp. 1-107.] they give a summary of some previously published Rothamsted results, chiefly relating to nitric acid in soils and subsoils; also of the results of Cameron, S. W. Johnson, Hampe, Wagner, and Wolff, on the assimilation of nitrogen by plants, from more or less complex organic bodies like urea, uric acid, hippuric acid, and tyrosine. A number of new determinations of nitric acid in soils and subsoils, and of total combined nitrogen in the surface soils of the Rothamsted experimental plots are given; and also the results of numerous experiments with dilute solutions of organic acids on soils, to ascertain the action of such dilute acids, in some degree comparable to the acid sap of the roots of plants, on the organic nitrogenous matter of soils. In the second part of the memoir are summarised the recent results and conclusions of other workers relating to the fixation of free nitrogen.

Probably the results of Berthelot, which have from time to time been published in the *Comptes Rendus*, have influenced the opinions and the course of inquiry in recent years more than any others. In 1876 and 1877, Berthelot found that various organic compounds, under the influence of the silent electric discharge, even of low tension, were able to fix free nitrogen, and concluded that such fixation of nitrogen takes place in ordinary soils under normal conditions. In 1885 he published results showing the fixing of free nitrogen by certain soils under conditions which led him to believe that the action must be due to the influence of micro-organisms, and to such action M. Berthelot seems now inclined to impute most influence in the matter. Although the gains in nitrogen, expressed in per-centages, were very small, yet there was gain in all cases when the soils were exposed either in the open, or in a room, or in closed flasks, and no gain when the soils were sterilised. Unless there be some unrecognised source of error, such as might easily be imagined in the case of the freely exposed soils, one seems bound to accept Berthelot's conclusions. Dehérain's results at Grignon are next discussed; they are chiefly on the gains or losses occurring on experimental field plots, and are perhaps not of such a nature as to materially assist one at the present stage of the inquiry.

Joulie's results, as given in the *Bulletin de la Société des Agriculteurs de France* in 1886 showed exceedingly large gains of nitrogen, which he is inclined to ascribe to the action of microbes; here the gains of nitrogen were certainly more than take place in ordinary farm practice, and occurred with Buckwheat, which is not usually considered as a "nitrogen collector."

Dietzell's experiments are mentioned; in all cases but one, in which there was a slight gain in nitrogen, the results are fully accordant with established facts. B. Frank, who has recently written a paper on the whole aspect of the question, has published some experiments of his own. He concluded, as have others, that two opposite actions are at work in the soil—one setting nitrogen free, and the other bringing it into combination, the latter being favoured by vegetation—but that there is no decisive evidence to show how this combination is brought

about; it does not necessarily follow that the plant itself effects the combination. Some of Frank's experimental conditions, however, were considerably removed from those occurring in the ordinary course of farm practice.

The very important and most interesting experiments of Hellriegel and Wilfarth follow. The first of these were described at the Berlin meeting of the *Naturforscher-Versammlung*, in 1886; subsequent experiments were described at the Wiesbaden meeting in 1887, and they were further given in a paper by König, published in Berlin in 1887; but the full text and details of their work were not published in time for Messrs. Lawes and Gilbert to refer to. A paper on these results appeared last November in *Beilageheft zu der Zeitschrift des Vereins für die Rübenzucker-Industrie*, and the work of these investigators is described by M. Vesque in the January number of *Annales Agronomiques*.

The experiments date from 1883 onwards, and were on cereals, Buckwheat, Rape, and various leguminous plants. The plants were grown in pots in washed siliceous sand, to which the necessary cinereal constituents were added. In this all the plants grew normally until the nitrogen in the seed was used up; then the plants not belonging to the Leguminosæ ceased growing until supplied with some combined nitrogen, nitrate of soda was used, when growth was proceeded with almost exactly in proportion to the amount of nitrogen supplied. With the Leguminosæ the results were more eccentric; sometimes the plants died of nitrogen-hunger; sometimes after a time of such hunger they recovered and produced abundant growth. To the sterile soil with the young plants there was added in a large number of cases a small quantity of an extract of a garden soil; the extract used contained less than one milligramme of nitrogen; the Oats, Rape, and Buckwheat remained undeveloped, but the leguminous plants soon became deep green and grew vigorously. If the soil extract were previously sterilised by heat, it produced no effect. Moreover the soil used in the preparation of the extract was of importance; with Peas any soil extract answered, but not so with Lupins and Sainfoin. With these plants, to render success certain it was found necessary to use an extract of a soil which had previously grown the same plants. Some experiments were also made in large sealed flasks, to which carbon dioxide was admitted at intervals; in these the results were practically the same as in free air, showing that it was not the combined nitrogen of the air which was absorbed.

It was also found that whilst on the leguminous plants which developed well, either with or without the addition of soil extract, the characteristic tubercles of papilionaceous plants were well marked, on those which did not develop in the sterile soil, and also on plants grown in sterilised soil to which nitrate had been added, and which plants developed at the expense of the added nitrogen, but did not assimilate free nitrogen, there were no tubercles. Hence there is obviously some connection between the production of the tubercles and the assimilation of the free nitrogen. In all cases where free nitrogen is presumably assimilated by the plant, the soil is also enriched in nitrogen, the more so when the plant growth is more vigorous, and this excess of nitrogen in the soil is almost entirely in organic combination.

The general conclusions are that leguminous plants, though they are able to make use of combined nitrogen in similar forms to those the gramineous plants utilise, yet differ from this latter order of plants in being able to use some other form of nitrogen, not that existing in the soil. This second source of nitrogen must be the free nitrogen of the air, which the Leguminosæ utilise through the agency of certain micro-organisms which are in symbiosis with them, and exist in the tubercles of the roots of this order of plants.

The results obtained by Von Wolff at Hohenheim from 1883 onwards are mentioned. Wolff is not inclined to admit that plants assimilate free nitrogen, but thinks that the only remaining hypothesis is that certain plants can appropriate the combined nitrogen of the air, either directly through their leaves or more probably after absorption by the soil. A porous soil probably absorbs far more nitrogenous compounds from the air than an equal superficial area of dilute acid, as used in experiments by Schloessing, Kellner, and Müller. He admits, however, that it is difficult to see why the grasses are unable to benefit by this equally with the legumes.

W. O. Atwater has published three papers on various aspects of the subject in the *American Chemical Journal*. In these papers he gives results of his own experiments and also discusses those of others. He concludes that in many of his experiments with Peas, when the growth was normal, half or more of the total nitrogen of the developed plants was obtained from the air. In what way the nitrogen was acquired the experiments do not show, but Atwater inclines to the idea that the plants themselves directly acquired the atmospheric nitrogen. The conclusion of this second part of the memoir gives some recent experiments and opinions of Boussingault on the subject. He remained strongly of the opinion that plants were unable to assimilate free nitrogen; although, as is here pointed out, some of his experiments in 1858 and 1859 with Lupins might be considered as leading to such a conclusion.

The third part of the memoir gives a summary and general consideration and conclusions. Regarding the evidence relating to other sources than free nitrogen, Lawes and Gilbert have shown that the amount of nitric acid remaining in a soil is much less after the growth of a crop than under corresponding conditions without a crop. Also that nitrification in soils is more active where leguminous crops are grown than where gramineous plants only are present; and that deep-rooted

leguminous plants like *Medicago sativa* or *Mcilolus leucantha* take up more nitric acid from the soil than shallower-rooted leguminous plants like *Trifolium repens*. But the supply of nitric acid in some soils, such as Clover-exhausted land or Bean-exhausted land, is inadequate to account for the nitrogen taken up by other leguminous crops grown on such land. No very definite conclusions could be drawn from the Rothamsted experiments as to the power of the acid sap of roots to take up nitrogenous organic matter from the soil, though it is seen to be not improbable that green-leaved plants can "take up directly, and utilise, bodies rendered soluble within the soil by the action of their acid root sap."—E. K. (in *Nature*).

(To be continued.)

HARDY FRUIT GARDEN.

SELECTIONS OF FRUIT.—*Apples*.—A good selection of dessert varieties, which may be grown either as cordons, espaliers, pyramid, or bush trained, would be obtained by planting Beauty of Bath, Irish Peach, Worcester Pearmain, Kerry Pippin, King of the Pippins, Gravenstein, Cox's Orange Pippin, Margil, Fearn's Pippin, Ross Nonpareil, Braddick's Nonpareil, Adam's Pearmain, Rosemary Russet, Ribston Pippin, Cornish Gilliflower, Court Pendu Plat, Lord Burghley, and Sturmer Pippin. All these are good bearers of first-class quality, and are given nearly in their order of ripening. If another half a dozen are required these may well consist of Cornish Aromatic, Court of Wick, Sam Young, D'Arcy Spice, Wyken Pippin, and Cockle Pippin. A corresponding list of culinary varieties would consist of Keswick Codlin, Lord Suffield, Duchess of Oldenburg, Stirling Castle, Emperor Alexander, Golden Noble, Cellini, Cox's Pomona, Lord Derby, Ecklinville, Bramley's Seedling, Lady Henniker, Lane's Prince Albert, Kentish Fillbasket, Blenheim Pippin, Winter Greening, and Norfolk Stone Pippin; Loddington, Tom Putt, Warner's King, Brabant Bellefleur, Dredge's Fame, and Brownlee's Russet being also desirable culinary varieties. The following is a good selection for orchard planting:—Keswick Codlin, Duchess of Oldenburg, Emperor Alexander, Hoary Morning, Manks Codlin, Kerry Pippin, London Pippin, Lemon Pippin, Reinette de Canada, Lane's Prince Albert, Beauty of Kent, Bramley's Seedling, Blenheim Pippin, Northern Greening, Dumelow's Seedling, Brabant Bellefleur, French Crab, and Tower of Glammis. Alfriston, Annie Elizabeth, Hanwell Souring, Galloway Pippin, and Warner's King are also profitable orchard varieties. Any Apple it is desired should attain a large size ought to be grafted on the Crab stock, but the most productive miniature trees are those on the dwarfing English Paradise or Doucin stock.

Pears.—The best thirty dessert Pears, arranged somewhat in their order of succession, consist of Jargonelle, Williams' Bon Chrétien, Beurré d'Amanlis, Flemish Beauty, British Queen, Beurré Superfin, Beurré Hardy, Louise Bonne of Jersey, Beurré Diel, Doyenné du Comice, Maréchal de Cour, Marie Louise, Pitmaston Duchess, Thompson's, Huyshe's Prince Consort, Hacon's Incomparable, Winter Nelis, Beurré Bachclier, Beurré d'Aremberg, Glou Morceau, Huyshe's Victoria, General Tottleben, Beurré Sterckmanns, Josephine de Malines, Bergamotte Esperen, Easter Beurré, Beurré Rance, Elisa d'Heyst, Olivier de Serres, and Madame Millet. All of these can be grown as espaliers, fan shaped, and cordons against walls, and all with the exception of Jargonelle and Josephine de Malines are suitable for pyramidal and bush training, though the fruit of Glou Morceau and Easter Beurré are seldom of much value from other than wall trees. The natural or Pear stock is the best in all cases where vigorous trees are required, the dwarfing or Quince stock being desirable when smaller quickly fruiting trees are required. The following Pears will do well in orchards on the Pear stock:—Williams' Bon Chrétien, Hesse, Louise Bonne of Jersey, Windsor, Fertility, Beurré Capiaumont, Eyewood, Clapp's Favourite, Marie Louise, Hacon's Incomparable, Beurré Diel, and Jargonelle. The six best stewing Pears are Vicar of Winkfield, Verulam, Catillae, Gilgil, Black Worcester, and Uvedale's St. Germain's.

Apricots.—These will not succeed in all gardens, and require a sunny wall in any case. The best are Early Moorpark, Large Early Moorpark, Roman, Hemskerk, and Shipley's. Apricots are not unfrequently grown as standards, but only in the most favoured districts do they succeed satisfactorily. The most reliable for this purpose are Breda, Turkey, and Brussels.

Cherries.—For wall culture the best six varieties are Early Rivers, Black Tartarian, May Duke, Elton, Late Duke, and Florence. The Morello is the most profitable on cool walls, and this, Black Tartarian, May Duke, Bigarreau, Governor Wood, Elton, Bigarreau Napoleon, and Early Rivers are well adapted for culture either as pyramids in the open garden or as standards in an orchard.

PEACHES AND NECTARINES.—The former under good culture will succeed as well against sunny walls as ever they did, but Nectarines are more fickle, these seldom attaining perfection without the aid of glass. A good selection of the former, arranged somewhat as they ripen, con-

sists of Hale's Early, Alexander, Dr. Hogg, Grosse Mignonne, Royal George, Alexandra Noblesse, Bellegarde, Barrington, Princess of Wales and Sea Eagle. In cold late districts the late varieties seldom ripen properly, but a trial ought to be given the first seven named. Nectarines that sometimes succeed fairly well are Balgowan, Stauwick Elruge, Hunt's Tawny, Albert Victor, Downton, and Elruge.

PLUMS.—For wall culture the most reliable and good in quality are Green Gage, Oullins Golden, Jefferson, Kirke's, Transparent Gage, and Coc's Golden Drop, and principally for culinary purposes—Early Rivers, Morocco, Victoria, Magnum Bonum, Pond's Seedling, and Goliath. Most of those named also succeed well as pyramids or bushes, while a selection for orchard culture should include Early Rivers, Early Orleans, Gisborne's, The Czar, Magnum Bonum, Prince Englebert, Prince of Wales, Victoria, Mitchelson's, Green and Purple Gage, and the Nectarine Plum. Damsons will thrive in almost any position. The Farleigh or Crittenden's Prolife is by far the most productive, but the quality of the common and Shropshire Damsons is superior.

FIGS AND GRAPES.—Neither of these are very generally or so much cultivated in the open as they were, being somewhat uncertain in all but the most highly favoured southern districts. A sunny sheltered position and a firm chalky soil best suits Figs, and if these conditions could be more often accorded there would be fewer failures. The varieties that prove the hardiest and most productive are Brown Turkey, Brown Ischia, and White Marseilles, the Brunswick, though somewhat shy bearing, being also grown extensively. Grapes fail if the wood does not ripen properly, and these therefore ought to be planted against the most sunny walls. Royal Muscadine is the most reliable variety, and with this may be planted the Early Ascot Frontignan.

SMALL FRUITS.—What are considered the best Black Currants are Lee's Prolife, Black Champion, Baldwin's, and Prince of Wales. Of Red Currants the most profitable are Scotch Red, Red Dutch, or Haughton Castle, and White Dutch is the best of the white kinds. Raspberries.—Carter's Prolife, Fastolf, Bee Hive, and Northumberland Fillbasket are all excellent, Semper Fidelis being a good late variety. If a yellow fruited variety is required, the Yellow Antwerp is recommended, and the October Red is the best for autumn bearing. Gooseberries are more numerous, and it is advisable to grow a greater variety of these in order to have a long succession of fruit. The favourite varieties are Early Sulphur, Early White, Large Whitesmith, Yellow Champagne, Ironmonger, Whinlam's Industry, Rifleman, Red Warrington, Rough Red, Crown Bob, Lancashire Lad, and Green Walnut.

MEDLARS, MULBERRIES, NUTS, AND FILBERTS.—The Dutch is much the largest Medlar, but the Nottingham is more productive, and by far the best in point of flavour. The Black Mulberry is the only variety recommended for culture in this country. The Thin-shelled and Dwarf Prolific are the best Walnuts, while the most profitable Filberts and Cob Nuts are the Lambert Filbert, White Filbert, Cosford, and Webb's Prize Cob.

WHEN TO ORDER TREES.—It cannot be too often pointed out how unwise it is to delay ordering till late in the season. Those that give their orders early are certain to get good trees of the varieties they need, but as there is usually a run on the best, and therefore usually the most popular varieties, the stock of these is liable to be exhausted quickly. Those who are wise therefore will decide at once what they will have, and lose no time in transmitting the order to a reliable nurseryman, who then will have no excuse for sending poor trees, or for substituting inferior varieties for those ordered.

FRUIT FORCING.

PEACHES AND NECTARINES.—*Earliest Forced House.*—The trees in this structure have been at rest for some time, and the roof lights having been removed the borders with recent rains have been well moistened down to the drainage. The house will have been thoroughly cleansed, the trees untied, pruned, dressed with an approved insecticide, rearranged and tied on the trellis, the border surface dressed, and all in complete order for a start when the time arrives. If, however, the roof lights have not been removed care must be taken not to allow the soil to become too dry at the roots of the trees, as that is sufficient to cause the buds to fall. If the trees are weakly or with too many buds, as they generally are this season, a supply of liquid manure whenever water is necessary will be of great benefit. The surface soil also should be removed down to the roots, not disturbing them, but supplying 2 or 3 inches thickness of good loam, and if the soil be light a fourth of clay marl with a bushel each of steamed bone meal, soot, and wood ashes to every cartload of soil, thoroughly incorporated, making it firm, and giving a good watering. Borders that are rich in humus from heavy dressings of manure or liquid manure may be dressed with freshly slaked lime an inch thick and mixed with the soil as deeply as practicable without disturbing the roots to any great extent, omitting the top-dressing before named. In treating borders it should be pursued on both the inside and outside. Complete the pruning and dressing, cleansing the house, admitting air to the fullest possible extent. The outside border being thoroughly moistened it may be covered with a few inches thickness of leaves with litter to prevent their being blown about.

Second Early-forced House.—The trees with us are leafless, and should be pruned (after untying), dressed, and rearranged on the trellis. This with a thorough cleansing of the house exterminates all insects before they have time to find safe winter quarters. We have some brown scale this year, and shall syringe with a wineglassful of petroleum to three gallons of softsoap solution, 4 ozs. of soap to the gallon,

and repeat it at least twice. In pruning early-forced trees it is not desirable to cut away much wood, nor indeed any kind of trees at the winter pruning, confining it to removing any useless parts that have escaped the knife at thinning after the fruit was gathered, and any long unripened shoots may be cut back to a triple bud, making sure that the centre one is a wood bud, or to a wood bud on well ripened wood. Shoots, however, that are well ripened need not be shortened under any circumstances, except to originate growths for furnishing. Those of from 8 to 12 inches length should not be shortened at all, as they have wood buds at the base and one at the extremity, the others being fruit buds. It is, however, a great mistake to retain much wood, which weakens the trees in flowering, and there is not space to train in the young growths without crowding. In other respects treat the trees, house, and borders as advised for the early house.

Third Succession House.—The trees are shedding their leaves and the buds are not too highly developed. We have a decided objection to large bloom buds on Peach and Nectarine trees, as those are the kinds that usually fall, if any do, and we think over-development as well as dryness at the roots with extreme fluctuations of temperature and hygrometrical conditions are the chief causes of the buds being cast. The roof lights have not been removed, as the wood is rather stronger than usual; such requires more time to mature than weakly or even the moderately vigorous—the best sort to have. The house having been kept rather close by day and thrown open at night, which has browned or hardened the wood, and the roots being kept moist, the buds are as plump as desirable, so that the roof lights will come off forthwith. Where the roof lights are not moveable care must be taken to prevent the soil becoming dry, and air must be admitted to the fullest extent, securing as complete rest as possible. Let no opportunity pass of pushing forward the pruning, dressing the trees, and having all needful work done.

Later Houses.—These may contain midseason or late sorts, in each case having fire heat to assist in spring at setting and in the early stages of growth, or in unfavourable weather during growth. The trees are beginning to cast their leaves, and where the roof lights are moveable, which ours are in all instances, it is advisable to remove them as soon as the foliage is down; but where green leaves hang long it is an indication of unripe wood, and the roof lights must not then be removed for some time longer, the trees being lifted and root-pruned. If this is performed carefully and judiciously it will not prejudice next year's crop, but it must be done whilst the foliage is still upon the trees, keeping the house rather close, the trees syringed, and the house shaded if the weather be bright. Under ordinary circumstances as to weather those precautions are not necessary. It is only when the trees are gross and the wood unripe that the particularly careful treatment is necessary. In the case of young trees it will suffice to take out a trench one-third the distance from the stem the trees cover the trellis and down, so as to cut off all roots to the drainage, leaving the trench open for a fortnight, not allowing the soil in the radius to become so dry as to distress the foliage to a severe degree of flagging, but not giving any so long as the leaves maintain their persistence, and then the trench may be filled firmly. This will check the tendency to a late growth and ripen the wood and buds.

Unheated Houses.—Peaches and Nectarines succeed well enough in some localities against walls under careful and judicious treatment, and in the majority they are more certainly grown under glass, and in some places attempting to grow Peaches and Nectarines out of doors, even in the most favourable aspect, is a waste of space, as such would be highly profitable put to more suitable purpose, as for instance for the choicer Pears and Plums. To afford a succession of Peaches and Nectarines over a lengthened period unheated houses are peculiarly appropriate, for which purpose have Alexander, *Hale's Early, Dr. Hogg, *Stirling Castle, Alexandra Noblesse, Bellegarde, *Barrington, Walburton Admirable, and *Sea Eagle. If more are wanted choose Condor, Crimson Galande, Grosse Mignonne or Belle Beauce, Noblesse, Royal George, Violette Hâtive, and Princess of Wales. Prince of Wales under glass does first rate; very large, highly coloured, and good in quality—indeed, one of the finest, but its constitution is not suitable for outside. Of Nectarines obtain *Lord Napier, Hardwicke Seedling, Rivers' Orange, Milton, *Pine Apple, Newton, Spencer, and *Victoria. Those only requiring a few sorts may select such as are marked with a star. It is, however, much the best policy to have divisions or separate structures for accommodating early, midseason, or late varieties. Early: Alexander, Hale's Early, and Dr. Hogg; Nectarines: Lord Napier and Goldoni. Mid-season: Stirling Castle, Alexandra Noblesse, Bellegarde, and Belle Beauce; Nectarines: Hardwicke and Rivers' Orange. Late: Barrington, Princess of Wales, Walburton Admirable, Sea Eagle, and Gladstone; Nectarines: Pine Apple and Victoria. The structures should have south or south-west aspects. We have one, however, for late on a west aspect which has been very satisfactory. The chief thing with trees in unheated houses is to train the growths rather thinly, so as to insure short-jointed wood; thoroughly solidified growth, to allow unobstructed light, and provide efficient ventilation. Proper attention must of course be given to cleanliness and due supplies of aliment. There is also the important consideration of retarding the blossom in spring as far as practicable. This we find best effected by removing the roof lights as soon as the leaves fall, and allowing them to remain off until the blossoms are swelling and showing colour. It also has a beneficial effect on the trees by the cleansing influence of rain and snow, and is well worth attention if only in securing the thorough moistening of the soil. Such trees can be kept perfectly under control

by occasional lifting and root-pruning, as may be considered expedient. Overluxuriance or a tendency to late growth is overcome by lifting, which should be done after the wood becomes firm, and whilst the foliage is still upon the trees. Intelligently practised lifting and laying the roots near the surface and firm soil is the surest remedy for trees that fail to set and stone full crops of fruit.

KITCHEN GARDEN.

TRENCHING AND DIGGING.—We do not approve of vacant vegetable quarters in winter, but as late Potatoes are dug and Peas or Kidney Beans are cleared away little can be done to refill the ground at this season, and as there is now plenty of time for trenching and digging these important operations should receive attention. Every garden is dug, but trenching is rarely attempted by those eager to work their gardens cheaply, but it is a great mistake to avoid it, as it is one of the most beneficial operations anyone can possibly engage in. The worst soils are improved rapidly by trenching, and the best will become more fertile under this treatment. There is little danger of crops failing in a thoroughly trenched soil, and let the weather or season be wet or dry advantageous results will follow in all cases. Unless actual rock is reached near the surface the soil should be trenched to a depth of 2 feet at least, or 6 inches more if possible. Refuse of a fertile character may be trenched down to these depths with excellent results, and this will afford considerable drainage to the crops. The surface should be left in a rough state, as the frost and wind of winter will soften and sweeten it for early spring seed sowing.

FORCING RHUBARB.—As the Apple crop is not heavy this year there will be early demand for Rhubarb. Too much Rhubarb is grown in some gardens. We often see large quarters from which half the crop is not gathered, and as this takes up ground that might be more profitably filled with other crops, we advise the early forcing of all surplus roots. Until Christmas or a little later Rhubarb is a profitable crop in the market, but in the spring months it is a difficult matter for small growers to make it remunerative. Roots four years old and onwards may be forced, and if well matured they will yield a good crop for cutting in November or December. They are rarely too old to force, and we have sometimes cut huge clumps in two, taken up one half to force and allowed the other to remain for a year or two longer. There are two good ways of forcing Rhubarb—one is to cover it with inverted pots, casks, or boxes, and place a quantity of fermenting material around them in the form of a hotbed. The other way is to lift the roots, place them in a Mushroom house, near a fire or under a warm stage, and in partial darkness. With a bottom heat of 85° or 90°, and a top heat of 70°, with plenty of moisture, the growths will appear in ten days after placing them in heat, and we have cut the produce in twenty-one days after treating it in this way in December. For private use two or three roots taken in every fortnight will give a constant supply.

AUTUMN-SOWN ONIONS.—These have grown well this autumn, but owing to the absence of sunshine they are somewhat tender, and if early or severe frost occurs they may suffer considerably. This may, however, be partially averted by shaking a little sand or finely sifted ashes along each side of the rows, and immediately afterwards put the foot on each side of the plants and tread the soil down all along and close to them as firmly as it can be pressed. The soil will not then retain superfluous moisture at the roots, the plants will become more robust and hardy, and they will pass through the winter without shrivelling at the points or withering at the roots, and when spring comes few will attempt to run to seed prematurely, an evil from which many suffer.

SPRING CABBAGES.—The same remarks and the same practice apply to these. When the plants are loose in the ground the wind upsets them, they form large flabby leaves, and suffer much by frost; but when the soil is very firm around them they grow robustly. Wind does not disturb them, and when the spring comes they are ready to begin forming heads and will be ready for cutting some weeks before the large-leaved plants, although these may appear the largest. Blanks should be made good, then draw a quantity of soil to the stems with a drag hoe, and tread round every plant afterwards. This is beneficial everywhere, but more particularly on light soils.

APPLYING LIME.—We never like to apply lime to the soil immediately before planting or sowing. In a fresh state it is apt to produce rust on roots, and scab in the Potato has often been traced to this cause, but if the lime is applied some months before the planting season the results will be beneficial. In carrying out the digging or trenching above suggested the lime should be introduced, especially to the soil near the surface, as it is there it is most wanted, and if applied there at present it will be washed through the whole by the spring. We apply it on the quarters in one or two barrowloads here and there, a quantity of soil is thrown over it, when it swells and hursts, and is dug in soon afterwards.

VEGETABLE REFUSE.—As fallen leaves are now plentiful and decayed vegetables are to be found in all gardens the present is the best of all times to form a heap of vegetable refuse. Everything in this form, as well as any old soil of a fertile description, helps to make a heap of manure. If placed together and mixed in a mound 3 feet or 4 feet in depth it will be well decayed by March, and in fine condition for digging in with Potatoes or any other crop.

WINTER TURNIPS.—Generally yellow Turnips or the Chirk Castle type are usually grown for winter, but in some cases these are not relished so much as the white ones, and where it is desired to keep the latter as late as possible the soil should now be drawn up over the roots

with a drag hoe. They are often somewhat tender, especially if of considerable size. When once touched by frost they will not keep for any length of time, and if protected by the soil before being injured in any way they will remain good throughout the greater part of the winter. We prefer this plan to lifting them, as when stored they are apt to shrivel, and they certainly become deficient in flavour.

LETTUCE AND ENDIVE.—Those nearly fully grown should be lifted with good balls of soil attached to the roots and placed close together in cool dry frames. A mixture of leaf soil and sand or any light material is best to apply about the roots, as they will not grow further, but only require to be kept fresh.

THE BEE-KEEPER

NOTES ON BEES.

DRONES AND DRONE COMB.

WHILE the important uses of drones cannot be over-estimated, we must not overlook the fact that the profit of hives may be rendered nil by having an excess of them. When a swarm is at first placed into a hive (unless in cases where the queen is unable to perform her natural duties) the bees at first, and according to the cluster, as a rule build worker comb. If the whole hive does not exceed in space the cluster of bees very little drone comb will be built, but where the hive is larger than the cluster immediately as the bees increase the remaining space is filled with drone comb, and often so when a comparatively young queen is in the hive.

If the queen regnant is removed and a newly fertilised queen introduced worker comb will be built, which is a proof that young queens are the best preventive to swarming, and that space will not prevent it, while it shows plainly that an excess of drone comb incites the bees to raise royal cells and to swarm.

While I readily admit the usefulness of drones in more ways than one, I cannot overlook the fact that beyond a certain limit they are absolutely hurtful, because the excessive laying of drone eggs exhausts the powers of the queen. Drones consume more food than workers, and beyond being mere heat-producers perform no labour. Seeing, then, that an excess of drones is an error, which can in no way compensate for a diminution of the workers, but is on the other hand a decided loss, and is no stretch of the imagination to say that where a twelfth part of the combs are drone it is a diminution of the ingathering of honey of at least 2 lbs. daily in ordinary honey weather. In 1863 I inadvertently left a frame of drone comb in several hives, the result being that very little honey was gathered from these hives, while a large surplus was taken from those adjoining. When drone comb is built and bred in towards the close of the season there will be no perceptible difference of honey gathering, but in all cases of early drone-rearing before the hive is full of bees there will be a decided loss to the bee-keeper. For long I have made it a rule to overhaul all my hives in autumn, replacing all drone comb with that of worker bees, as well as taking care that swarms are never allowed to build an excess of drone comb by filling unoccupied space with either combs or foundation in full sheets; but even with full-sized sheets bees sometimes build drone comb, but are more apt to do so with some makes than with others. I prefer the natural based cell with extra high side walls.

Hives that engender damp and mould throughout the winter destroy the combs; in all such cases the renewed combs are drone, resulting in an excess of drone comb in cases where the bee-keeper may have in the previous autumn guarded against it. Drone combs are regarded by some writers to be store combs built purposely by the bees for the storing of honey. A greater error than this could not be made. The first combs built by a swarm are always worker and at the crown of the hive where the honey is always stored, the drone comb mostly being built at the bottom of the hive, or lower edges of the comb; besides, in strong hives

with young queens it is seldom we have drone-combed supers and the removing of one or more filled supers, next to having a young queen, is the best preventive of swarming. When that cannot be effected, and other conditions are favourable to it, the removal of laden side combs will have a similar effect.

But the bee-keeper will do well to become impressed with the utility and non-utility of drones, as also with the causes of swarming and the means of preventing it, for without such knowledge bee-keeping will, instead of pleasure and profit, be one of disappointment and loss.

STIMULATIVE FEEDING.

It is a well known fact that I have always been opposed to slow feeding, as it is termed. A better illustration in support of my system could not be given than what occurred in my own apiary lately. Some of my nuclei at the end of August and early in September were fed a little simply to keep them alive until they were supplied with combs from hives having old queens. Although these nuclei were regularly, but sparingly, fed during the above-mentioned period, very few of them reared any brood. No sooner were they supplied with combs containing large stores so late as October, than without a single exception they all commenced breeding extensively, and to work in such a manner as to convince the greatest sceptic that stimulative or slow feeding is an error in bee husbandry.

PREPARATIONS FOR THE FUTURE.

The dark days will soon be upon us. Already we hear of preparations being made for Christmas, and no sooner have the leaves fallen than the buds in some cases appear swelling, as if spring was really at hand, although Dahlias in many cases are still flowering, and Primulas are also flowering freely, autumn and spring joining hands as it were. We do not know what is before us, whether the winter will be a severe one or not, but there is one thing certain, it will be as fleeting as usual, and although but beginning will soon pass away, but not without its long nights, a season welcome to many for the opportunity afforded of intellectual culture. I trust, therefore, that after what has been hinted at in the management of bees, all necessary requirements for the apiary will be prepared during the long evenings, so that nothing may be omitted that will ensure a prosperous apiary in 1890.—LANARKSHIRE BEE-KEEPER.

* * * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Books (C. T.).—Mr. J. Douglas's book on Hardy Florists' Flowers, and Mr. B. S. Williams' work on Choice Stove and Greenhouse Plants, will contain the information you require. (A. R.).—The book you name is one of the best of its kind.

Chrysanthemum Elaine and Mrs. Marsham (*Chrysanthemum*).—The National Society's catalogue gives Mrs. Marsham as synonymous with Elaine, and therefore it would not be admissible in a stand for distinct varieties.

Transplanting Box (*W. S., Berks*).—Box may be taken up and fresh edgings made now, or at any time when the weather is mild and the soil in free working condition. We have formed Box edgings with equal success in November and March. More, depends, however, on the way in which the work is done than on any particular time between September and April for doing it.

Training Pear Trees (*C. L. D.*).—If the Pitmaston Duchess Pear trees are on the Quince stock we should advise their being trained upright as No. 1, or five-branched vertical cordons, and if on the Pear stock they would preferably be trained fan-shaped, or as No. 2. That is not a good mode of training Pears; they are best when on the free stock trained horizontally, which you may readily do by taking the lowest pair of shoots to the right and left respectively of the stem, and to the lowest wire, the next pair to the wire above, and so on, the leader being cut back so as to be a few inches lower than where you wish to originate the next pair of shoots with their leader. This will not give so good a tree as if it had been treated with the object of horizontal training, but you will gain a year by following the plan indicated. The side shoots should not be shortened, but trained in their full length, it being only necessary to cut back the leader with a view to originate growth as desired.

Pear Trees Producing Cracked Fruits (*Idem*).—The only remedy is to root out the trees and plant fresh trees of varieties that are not likely to have the fruits affected in the way you describe, to which some varieties in certain localities are peculiarly liable, usually from the climate being too cold and wet. Select those known to succeed in the neighbourhood. The only thing that affords any mitigation of the attack is to lift the trees and replant them in entirely new soil, preferably the top spit of an old pasture. All the attacked fruit should be destroyed by fire, the leaves also being collected and burnt.

Vines Infested with Thrips (*H. T. H.*).—The leaves sent are badly infested with thrips. Coating the hot water pipes with sulphur in thin solution with milk will not, as far as we are aware, destroy them, but it is good against red spider and mildew. There is danger, too, in using the sulphur for too highly heated surfaces, as the fumes injure the skin of the Grapes. For the thrips no remedy is so safe as fumigation with tobacco, which should be done on two or three consecutive evenings when the weather is calm, and as this will only destroy the insect then present, the fumigation should be repeated in a week or ten days. The fumigation will not injure the Grapes, and the smell will pass off in a few days.

Grape having Muscat Flavour for Growing with Plants (*W. B.*).—No Grape has the Muscat flavour so highly developed when grown in an ordinary greenhouse as yours seems to be as Black Muscat (Muscat Hamburg). It, however, is subject under such conditions to have a large per-centage of stoneless berries, which to some extent may be remedied by fertilisation with Black Hamburg pollen. It is a capital cropper, and otherwise does well in a moderately heated house. Madresfield Court is a very much more satisfactory Grape, and though not having the full Muscat flavour as in Black Muscat, has a decided Muscat flavour, and it sets and swells freely, having fine bunches and berries. Of the two we should select Madresfield Court, for though liable to crack in some circumstances, we know it to be grown very finely indeed in a large house or conservatory that is always full of plants. Gros Colman requires a long season of growth, and consequently more heat than you would be able to command, and it has not a trace of Muscat flavour.

Apple Lady Henniker (*J. R. O.*).—In the "Fruit Manual" the following description and history are given:—"Fruit, very large, 3½ inches wide, and 3 inches high; roundish, narrowing a little towards the apex, and with blunt angles on the sides, which terminate in prominent ridges round the eye. Skin, yellow on the shaded side, with a faint blush of red, which is covered with broken streaks of crimson, on the side next the sun. Eye, large and open, with short segments, and set in a very deep and angular basin. Stamens, median; tube, conical or funnel-shaped. Stalk, very short, set in a very deep, wide, russet cavity. Flesh, very tender in the grain, well flavoured, and with a pleasant perfume. Cells, obovate; abaxile. A first-rate Apple, chiefly valuable as a cooking variety, but useful also in the dessert. October to February. This Apple was raised at Thornham Hall, near Eye, in Suffolk, and the account of it, furnished in the years 1840 and 1850 the late Lord Henniker had great quantities of cider made to give away in the summer months. Several bushels of Apple pips were sown in beds, from which the most promising seedlings were selected and planted; these were reduced every few years. The last thinning was about seven years ago, when thirty-three trees were cut out. The tree in question was always the favourite, and it has been carefully preserved. It is largely used here when large and handsome dishes of mixed fruit are required for the dinner table. Its appearance by lamp-light is most telling. The tree is very healthy, and a great bearer."

Ink for Zinc Labels (*W. S.*).—The proper ink for writing on zinc is nitro-muriate of platinum, which produces a jet-black indelible stain. This preparation is easily made, and at very little cost. Procure an ounce stoppered phial, into which have two pennyworth, or half an ounce, of nitro-muriatic acid (composed of two parts muriatic to one of nitric), which may be obtained of any chemist. Next obtain from the gunsmith an old platinum touch-hole, which may be had for a few pence; then putting the latter in the acid and leaving out the stopper, set the

phial in the sun or else upon hot sand until the acid has assumed a deep, rich brown tint, or that the metal has ceased to give off bubbles of gas from the acid becoming a saturated solution. A few drops of this should now be added to a little water and tried with a quill pen, adding drop by drop until a sufficient blackness is produced. When using great care must be taken to wash the writing thoroughly in plenty of water immediately it has blackened, and then it should be wiped quite dry and varnished as soon afterwards as possible. 2, Take one part verdigris, one part sal-ammoniac, half part lampblack, and ten parts of water; mix well, and keep in a bottle with glass stopper; shake the ink before using it. It will keep any length of time. Write it on the label with a steel pen not too fine-pointed. It dries in the course of a minute or two, and will endure for many years. Or, put into two-pennyworth of common writing ink two pieces of sulphate of copper the size of a hazel nut; let it dissolve, and write on the zinc with a quill pen.

Manures for a Garden (*R. A. C.*).—An excellent manure for all description of garden and field crops is formed by an admixture of the cow, pig, and horse manure and leaves. It will grow good crops of every kind. Not that we object to artificials, but yours being a light porous soil will have its staple added to in a manner that must constitute a permanent and ever increasing improvement as a rooting area, and correspondingly enhance its value for cultural purposes. Perhaps a dressing of lime would be most suitable in your case as a deterrent of club, but as that falls through on account of the expense, some mitigation of the effects may result from a judicious employment of artificials. Nitrate of soda is good, of which 1½ cwt. is sufficient for an acre. Nitrate of potash is also good, but the best form of potash is, perhaps, the muriate, which may be applied at a similar rate as the nitrate of soda. Superphosphate of lime is first-rate, almost indispensable to full crops of the Brassica family, 3 cwt. being a suitable dressing. Those well incorporated may be applied as a surface dressing at the time of putting in the crops, pointing it in lightly, or if drills are made as in sowing, that with the necessary raking will be all that is required. The quantity named is a full amount for one acre. For the pasture we should omit the nitrate of potash (saltpetre) and increase the quantity of steamed bonemeal proportionately, so that the mixture would be three-quarters of a cwt. steamed bonemeal, three-quarters of a cwt. nitrate of soda, and 1½ cwt. mineral superphosphate. February is a good time to apply it. Superphosphate of lime is bones dissolved with sulphuric acid. Mineral superphosphate is dissolved fossilised bones—i.e., coprolites.

Culture of Pleroma elegans (*M. O.*).—This is an evergreen shrub, with purple flowers produced in June. Repot in spring, and again in June for young plants, training in the pyramidal form, and stopping the growths up to July, so as to induce a compact habit. Established plants must be cut-in closely after flowering, and kept rather dry and cool for about three weeks, and then rather close and moist, being careful not to overwater; and when the young shoots are an inch long turn the plant out of the pot, remove most of the old soil without disrooting much, and repot in the same size of pot. Keep it rather close, moist, and shaded for a few days, then admit air moderately, and keep in a light airy position over the winter. In April shift it into a pot 2 to 4 inches larger in diameter, and the plant will be the better for placing in a Peach house started to ripen the fruit in June, the moisture from syringing and the well-ventilated atmosphere securing a stiff vigorous growth. Failing this convenience keep it in the warmest part of the house, but well ventilated, and syringed twice daily. In July place it in a cool airy house, shielded from midday sun. In September return it to the greenhouse, assigning it a light airy position. The shoots if growing irregularly may be stopped, but not after June, and they should be tied in autumn after the manner of Azaleas. If the plants are young they may be potted in June, in addition to spring potting; the plants will therefore have a season to grow in and another to flower, so that two sets of plants will need to be grown to have flowers every year. Sandy fibrous peat four parts, very fibrous sandy loam one part, and one part in equal proportions of pieces of charcoal, broken pots, and silver sand, well mixed, and used rather rough. The drainage must be good. Cuttings of half-ripened shoots, short and stubby, in sand over sandy peat, under a bellglass placed in a close frame, and gentle bottom heat, tilting the glass on one side at night to prevent damping.

Impatiens Sultani (*R., Surrey*).—The note to which you refer is probably the following, which appeared a few years ago:—Amongst the numerous conservatory flowering plants *Impatiens Sultani* ranks in my opinion as one of the best. With us it is exceptionally fine at the present time, flowering profusely. For cutting and table decoration I must admit we have better plants, but for the conservatory it is most valuable, especially at this time of year. It is generally known it can be had in flower all the year round with a succession of plants; but the time it comes in most useful to us is in September and October, and I think in most establishments it will be welcomed then, as in October flowering plants are very scarce. My mode of having plants in bloom at the above-mentioned time is to insert cuttings about the middle of May. They will strike easily in any ordinary potting soil finely sifted, with a good sprinkling of sand. Place them in a bottom heat of 80°; shade from sun. When struck transfer them into 60-size pots. The soil that I find to suit them best is equal parts of loam and leaf soil, with a little sand and bone dust added. Place them in a good steady moist heat till the plants root into the new soil, and then gradually harden them in a frame. Examine the plants at intervals to see if they want potting, as it is a great mistake to let the pots get too full of roots. The final shift

is into 32-size, or 6-inch pots, the same compost as before. Place the plants as low down in the pot as possible, so as to leave room for a top-dressing a little later on, the compost for top-dressing to consist of a mixture of leaf mould and spent Mushroom dung, with a little sand and bones added; this last addition will greatly benefit them. Never stop the points of the plants; let them grow in their own natural way, as I think it is far the best. About the beginning of September take them out of the frame into a conservatory. Stake the plants out as they require it, as when placed in conservatory, especially in dark places, they get drawn. Keep the plants in as light a place as possible, as these flowers come a much better colour. The brilliant display they make till the Chrysanthemums are brought in will well repay for the trouble bestowed on them.

Vines Unsatisfactory (M. S.).—The Vines will need thorough renovation of the border so as to rejuvenate them. From the crops of Grapes being a "long way from satisfactory," and the bunches "shanking badly," the roots are in a very unfavourable rooting medium, and no wonder, as pigs that have died on the farm are buried in it, and night soil has been put upon it. Night soil is poisonous to Vines when applied so recklessly. Animal matter must be decomposed and pulverised with lime and soil, and night soil mixed with wood ashes, to become safe fertilisers, they then form a valuable manure. In the absence of any roots near the surface it would be of no use applying rape cake or other manure, and it would be sheer waste to do so. New roots are wanted, and until they are produced the Vines will never yield good Grapes. The proper way to proceed would be to remove the soil down to the roots, and if the drainage be good it would only be necessary to take the old soil from amongst the roots and lay them in fresh material nearer the surface. As the Vines have only an outside border care will be needed so as not to injure the roots. Indeed all should be preserved as far as practicable, and they should be kept as much as possible from the atmosphere. If the drainage be bad it ought to be rectified, which may necessitate the lifting of the Vines and remaking the border. If not in very bad condition it would perhaps be sufficient to take part of the old soil away, bring up some of the roots, and add new soil as you propose. In no case should the uppermost roots be deeper than 4 inches, mulching with the same thickness of short but not soapy manure. If the leaves are not off the Vines it would be advantageous to do the work now. Failing any attempt at lifting, a dressing of lime a couple of inches thick may be given, and mixed with the soil as deeply as can be done without disturbing the roots, taking advantage of any roots lying near the surface or proceeding from the collar to raise them and lay them in the fresh soil from 4 to 6 inches deep. If you could pick out the soil for a yard or more around each Vine and quite up to the stem, replacing it with fresh material, fresh roots would be produced that would permeate the soil, changed by the lime into a more suitable and abundant source of food. Encourage fresh growth on the Vines another season, but do not crowd the foliage, a good spread of foliage exposed to light being a good preventive of shanking.

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (M. T. S.).—1, Claygate Pearmain; 2, Fearn's Pippin; 3, Cox's Orange Pippin; 4, Golden Spire; 5, Kerry Pippin. (R. O.).—1, Apple, Lady Henniker; see reply on preceding page; 2, Pear, Pit-maston Duchess; 3, Pear, Marie Louise. (S. R. T.).—The Pears are—1, Durondeau; 2, Beurre Bosc; 3, Catillac; 4, Doyenné du Comice. Several packages of fruit which arrived late are reserved for examination, and the names will appear in the next issue.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (W.).—1, Yes, it is *Anemone japonica alba*; 2, A seedling variety of the *Rhododendron javanicum* type, but inferior to many of those already in commerce; 3, *Dahlia glabrata*. (Orchid).—It is *Oncidium Forbesi*. (J. II.).—Owing to the specimens being so much withered we have failed to identify them. (L.).—It is *Bulbophyllum umbellatum* undoubtedly, and was figured in the "Botanical Magazine," t. 4267; and in the "Botanical Register," vol. xxxi, t. 44; also in this Journal last week. It is sometimes seen under the incorrect name you give.

TRADE CATALOGUES RECEIVED.

THE FLOCK IN WINTER.

UPON the principle that a farm should be self-supporting and generally independent of help from without, a selection of the best ewe lambs is made every year for addition to the ewe flock. This selection is made when they are withdrawn from the ewes in June. They are kept apart from other sheep, and have the best grazing, with a few crushed oats to promote quick growth and fairly high condition; they are then ready for the tup at the age of from seven to eight months, the tups being turned in with them three or four weeks later than they are to the older ewes. Forward hoggets will average about a lamb apiece; but if they have not had special

care, and are at all low in condition, the average falls by about a third. Results show that this breeding from such young animals is in every way desirable. We have heard fears expressed that it would stunt the growth and prevent the full development of the ewes, but we can confidently say it does not do so. We have now a half-bred flock of full-mouthed ewes, which we bred and took a lamb from the first year, and they are certainly all fine sound animals. Half-breds and Black-faced Suffolks crossed with Hampshire Down tups answer well for this purpose, but we have also been fairly successful with pure-bred Southdowns.

It is not too late now for a trial of a certain number of ewe lambs should any of our readers feel disposed to test what to them may be a novelty; but without early selection and the special care we have indicated a full measure of success must not be expected. We have known more than one attempt at breeding from ewe lambs fail for want of a little care, and those who thus fail generally condemn the plan outright, upon the assumption that where they have failed success is an impossibility. Now a four-shear or full-mouthed ewe is considered old, and many breeders discard them at once from the breeding flock. If they are home bred, are sound and healthy, and have a good record in the lambing fold we usually take another lamb from them. At best, however, the life of a ewe is a short one, and it is most desirable to render it more profitable by breeding as early as possible. At the outset a flock has to be got together by purchase; afterwards all ewes should certainly be home-bred, and the tups procured from another flock, a little extra outlay upon tups always being a sound investment.

Whether breeding ewes are hoggets or older sheep, all must be kept from root^s before lambing, as we explained last week. Thousand-headed Kale is plentiful enough this year, and with a change to grass it may form the chief food of the ewes till lambing. It is well to have plenty of dry food close at hand in December and January in readiness for snow. So many estates now have other farms in hand beside the home farm, that reliance is often placed upon off-hand farms for a supply of fodder, and the means for obtaining a speedy and prompt supply should always be forthcoming. There must be no falling off in the condition of a pregnant ewe; it has the foetus to nourish, and when the lamb falls if we would have a full supply of milk the ewe must have plenty of sustenance. We recommend a few Mangolds on the near approach of lambing as a wholesome addition to the dietary, and some crushed Oats mixed with bran and chaff should be given regularly in the troughs. The plentiful secretion of milk is natural to a healthy well nourished ewe, but the ewe should be kept in fair condition all the year round. This is a point of much importance, and there can be no greater mistake than to keep lambs with ewes late into July. We have seen ewes taken from the lambs in wretched plight, just so many "bags of bones," and we fail to see how they are to be brought into condition and breed fine lambs in the following season. No doubt it is owing to such mismanagement, such a system of extremes, that there are so many ewes with little or no milk for the lambs; that they also often have not strength to bring forth the lambs; that they die in labour or suffer from one or other of the ailments peculiar to the lambing season. There is no such thing as luck in connection with the management of a ewe flock; cause and effect tell in this as in all other things, and it is our aim to explain the cause of success or failure, upon the principle that prevention is better than cure. In point of fact cure is not always a possibility, and the cause of debility, or worse, is but too often so remote that it is impossible to trace it. To do so is nevertheless always desirable in view of avoiding such mismanagement in the future.

(To be continued.)

WORK ON THE HOME FARM.

The very heavy rainfall has saturated the land, and Wheat sowing is out of the question for the present. While the weather continued

fine, and the land was dry and firm, the temptation to get the roots off the land was so great that many farmers allowed the Wheat sowing to be held in abeyance for a while, and now they will have to wait a bit before the soil will be dry enough to be worked. Under such weather conditions the advantage of drainage and mechanical division is seen in the short time required before drills and harrows can be at work again. We know some farmers who have finished sowing winter corn. There are others who have only just begun ploughing for it, and it will always be so. The prudent man will lose an hour after harvest, but will turn the brief spell of fine weather remaining to account for the most pressing autumn work. When once the weather becomes broken now it may continue so for an indefinite period of time, and late sown Wheat points to a backward harvest. Very much Wheat is sown after Clover, and where the second growth of Clover has been folded with sheep the plan is a good one. Care must be taken not to plough too deeply, and upon the principle that for Wheat a firm seed bed is indispensable it is good practice to use a Cambridge roll once or twice after the drill. Wheat so often loses plant in spring from looseness of soil that all that is possible should be done now to prevent it. After all there is nothing in Wheat culture that commends itself more strongly to our notice and approval at this season of the year than a field sown in September, that is now a full strong plant thoroughly established in the soil. We have no fear of injury from its becoming winter proud—that can always be corrected, and it is far better to have the plant well established now than for it to be hardly visible till the end of the year. As to the sorts of Wheat, we do not hesitate to sow White and Red in autumn, provided the land is sound. Certainly we have not found Champion White Wheat at all delicate, and it always commands a brisk sale at the highest market price if its condition is faultless. Perhaps this Wheat and a good selection of Square Head are about the best for general use.

BUTTER AND GHEE.

In your article "Midsummer Butter," in the *Journal of Horticulture* for the 4th July last, you say that the best butter is made after "haysel," but which, owing to glut, only fetches half price. Then, again, "if such would-be leaders of the farmer would show him how to preserve his butter so as to hold it in reserve till winter that would indeed be helping him." Why don't you do with your butter as we do out here, make "ghee" of it—that is, clarified or "gan" butter? In this country we never use dripping or lard for cooking, only ghee. Cannot you introduce ghee for cooking purposes into England? Really good and well-made ghee is delicious both in taste and fragrance—as nice as Everton toffee. Why not make midsummer butter into ghee, and send it to such large seaport towns as Calcutta, Bombay, Madras, and Kurrachee or Colombo, where it will always fetch good prices? Properly well-made ghee will keep for years. It is very difficult to get good ghee in large towns in India, owing to extensive adulteration. Ghee making was tried in Australia, but I do not know with what result.—A. BANON, *Kooloo-Kangra-Punjaub*.

OUR LETTER BOX.

Bromus giganteus (R. W. P.).—This forage plant will not usually produce like Italian Rye Grass when the imported seed is sown in the autumn and early spring months; and as summer forage we prefer Giant Sainfoin or Lucerne, both for quantity and feeding value, the latter especially when a quick succession is required as green fodder for dairy cows. There is, however, always the question of soil to be considered, and we therefore recommend a trial of these four sorts to ascertain which is the best.

REMARKS.

20th.—Heavy rain till 9 A.M.; wet morning, and showery afternoon and evening.
21st.—Dull early, wet morning, a little sun at midday, then damp and showery again.
22nd.—Dull and drizzly till 10 A.M., and overcast all day.
23rd.—Overcast all day, with occasional spots of rain in the afternoon.
24th.—Rain in small hours; cloudy morning; fine afternoon and evening.
25th.—Bright all day, spots of rain in the evening.
26th.—Fine, and frequently bright.
A damp and rainy week; temperature about the average, with little range.—
G. J. SIMONS

WINNING AND LOSING PRIZES.

DURING the next three weeks more prizes will be won at exhibitions in various parts of the kingdom than have been awarded in a similar period of time since last November. That fact denotes earnestness of purpose on the part of cultivators of Chrysanthemums and other plants, also fruit, which can be presented in the best condition at this season of the year. The crowds of spectators who inspect, admire, and criticise the exhibits also afford conclusive evidence of the popularity of autumn shows of the nature indicated, and these no doubt give a great impetus to higher cultivation, as well as gain new adherents to a pursuit that is worthy of being engaged in by the greatest possible number of persons of various grades in the community.

Than the cultivation of plants, fruit, and vegetables, according to the means and preferences of individuals, with the tasteful association of flowers for room adornment, we cannot imagine any occupation more deserving of encouragement, and there is no other way in which encouragement can be so effectually given as in offering rewards for the best examples of production. For these the most skilful and earnest strive, while others are stimulated to higher endeavour in the discharge of their duties as gardeners, or in the exercise of a delightful occupation as amateurs. The great increase in November exhibitions, and their markedly improved character, show what can be accomplished by the co-operation of both those classes—those who work in gardens for the means of livelihood, and those who devote their time to the organisation and management of societies and shows as a labour of love. The success of many gatherings, such as those under notice, is largely due to the willing workers last mentioned, and credit should be ungrudgingly accorded them for their valuable aid and disinterested efforts.

Passing to the growers, these must not, cannot be overlooked, for not only is the work of those who win prizes deserving of public recognition, but those who try to win and fail are entitled to be remembered as important contributors to the aggregate success of our exhibitions, for if only prize stands and collections were included, the displays would, of necessity, be seriously reduced in extent, while deprived of the interest that attaches to diversity and of the instructiveness that is found in a comparison of the relatively good with the relatively inferior. There is no fear, however, of all being prizewinners, especially where there is a reasonable gradation in the value of the awards provided. A sensational first prize, then a sudden fall to almost insignificant amounts, can scarcely be expected to incite competition. The plan may answer in an isolated case, and for a year or two, but it is extremely improbable that it can long find favour with the majority of cultivators. A nearer approach to equalisation in amounts would in all likelihood meet with more general approval, and in most classes the plan would be equitable, for in many of them the difference in the amounts is out of all proportion with that of the exhibits. For instance, if a sum of say £14 were apportioned in four prizes of £5, £4, £3, £2, it is practically certain that a better response would be made than if £15 were divided into three prizes of £10, £3, and £2. But under any circumstances more prizes will be lost than won during the present campaign, hence disappointment must preponderate over jubilation among exhibitors.

Some will bear their misfortune bravely and resolve to repair

it; others will feel bound to express their chagrin, and in a moment of irritation aver they will not stage at the same show again—at least under the same judges. These persons, however, generally alter their minds if they have anything of special merit, and when they win no fault is found with the adjudicators. It is not suggested that those officials cannot err. Some of the most experienced have occasionally overlooked something in the conditions, but as a rule they are very glad to have this pointed out. A formal protest in reasonable terms, and the grounds stated, will insure a re-inspection and, if called for, a rectification; but after the second examination, let the result be what it may, the question should be regarded as settled, and if the officials of a show are satisfied that justice has not been done they must be left to make the best amends they can and employ different men to act another year. All objections to awards should be made in a calm business-like way to the secretary, noisy contentions in a show room being the reverse of creditable to those who share in them, while they are highly distasteful to visitors and may be damaging to a society.

It should always be remembered that judges who are worthy of the position are supremely disinterested. They do not wish to know the names of competitors, and care only to discover the faults and merits of what may be under examination, not giving a thought to whom the products belong. If they acted on any other principle they would be totally unfitted for the important duty with which they were entrusted, and it is safe to say they would soon be “found out.” Assuming that the adjudicators employed are competent, and a prize, it may be a third prize of small amount, is lost to an exhibitor who ought to have won it, there is the possibility that the judges are not alone in fault. No one who has had long experience in connection with exhibitions can ignore the fact that in the case of not a few the rules and regulations might as well not be printed, so far as they relate to the hour at which the judging must commence. The encroaching of exhibitors on the time of the adjudicators often compels the latter to “rush through” their work in about half the time that is necessary for doing it properly. If, for whatever reason, exhibits must be admitted long after the stipulated time for the completion of the work, an additional number of judges should be employed in order that the awards can be made in a satisfactory manner before the inrush of exhibitors and general visitors. That is an important matter for insuring accuracy, and there can scarcely be a doubt that more errors occur through hurried work, the direct result of unpunctuality, than from all other causes; yet the man who is half an hour or more behind time in arranging his exhibits, and who loses a prize he thinks he ought to have won, forgets that if the rules had been adhered to he would not have had even a chance of winning. The men who win the best and the most prizes are seldom late in staging.

These remarks are founded on experience gained over a series of years at exhibitions in various parts of the kingdom, and they are recorded with the object of impressing on all the desirability of assisting as far as they can, and in the best way that is open to them, in making the November gatherings enjoyable and satisfactory. One word more on winning and losing prizes. To win modestly and lose manfully are virtues, and those who possess them are held in the highest esteem in the horticultural world.

PREMATURE DEFOLIATION OF PLUM TREES.

In the early stages of leaf development Plum trees are peculiarly liable to attacks of aphides, especially if cold easterly winds are prevalent and prolonged. These differ somewhat from the common green fly, which, however, changes colour with the species of plant or colour of wood and foliage attacked, therefore difference in colour is not to be taken as constituting a specific difference. The aphid attacking the young shoots, tender leaves, and sometimes the insipid clusters of fruit of the Plum trees is invariably of a very

light green with a decidedly blue tint, shining, and with a mealiness in its location rendering it less assailable by water or insect-destroying solutions than common green fly—indeed, it is rather difficult of dislodgement and destruction, yet not so hard to kill as brown or Peach aphid, nor so impervious of attack as black or Cherry aphid. Plum aphid (*A. pruni*), however, gives trouble enough, and if unrestrained prejudices the crop, causing the fruit to be cast or preventing its development, the deposits also interfering with the proper elaboratory functions of the leaves. What with the sap abstracted and the deposition of honeydew upon the leaves, which sooner or later is taken possession of by a black fungus, the trees are greatly impoverished, the fruit being ill fed and the foliage falls prematurely. Nor does the mischief end with the current crop, as the foliage being cast early the wood is poorly stored with food, and the bloom buds do not attain to full development. In result the trees may blossom beautifully, but very little will set, or if setting the insipid fruit does not swell, being lost in its early stages. The remedies for aphides are legion. Tobacco water—one gallon of tobacco juice diluted with six gallons of soft or rain water syringed over the trees so as to thoroughly wet the whole, particularly the young growths and the under sides of the leaves, is effectual. Apply it on a calm warm evening, and wash the trees with clean tepid water the following evening, or if the attack be severe repeat the application of tobacco water, and thoroughly cleanse the foliage the following morning by syringing with clear tepid water. Tobacco water may be made by soaking 1 lb. of the strongest shag tobacco in six gallons of boiling water, covering it, and allowing it to remain until cool, then strain it through a hair sieve; 1 lb. of softsoap added will render it more efficacious. Of all the remedies soapsuds, where bleaching powder or much soda is not used, is a cheap, easily obtainable, and a good killer of aphides. The suds ought to be strained through a hair sieve, and syringed over the trees in the evening. Unless, however, it is known for certain that soap and a little soda only are used it is perhaps best to leave soapsuds alone, though when they can be relied on they are excellent as a wash for fruit trees from the fruit setting until midsummer, the soapsuds being followed within twenty-four hours with clean cold water, forcibly applied with a syringe or engine. Nothing surpasses soapsuds and cold water as a Plum aphid destroyer.

To show that there is no excuse for premature defoliation of Plum trees through attacks of aphides we may mention a solution of softsoap, 4 ozs. to the gallon of water, as handy and effectual, and all the more so if a gallon of tobacco water be added to every five of the soap solution. In the soapsuds we have soda, and in softsoap potash, which constitutes the difference between hard and soft soap. The soaps have a decidedly alkaline reaction, the proportion of alkaline bases being 8 to 9 cent. of soda and potash respectively. Then there is quassia water—1 lb. quassia chips boiled in four gallons of rain water for a quarter of an hour, allowed to cool, and after straining 1 lb. softsoap is added, and when thoroughly dissolved syringe the tree thoroughly on a calm evening, and follow in half an hour with clear tepid water.

There are many other insecticides, all of which are, so far as we have tried them, efficacious when the directions are strictly followed. Plum aphides, however, require a rather stronger application than is advised for green fly, and sometimes it is very tenacious, in which case gas liquor may be used, diluted with not less than twice its bulk of water. If used too strong it will brown the foliage, therefore it is well to use two parts of water and one of the gas liquor, well drenching the trees with a fine-rose syringe or engine, and wash off with clear water the same evening as the diluted gas liquor is applied. Repeated on two or three consecutive evenings it is certain to effect its purpose, and is equally useful against brown and black fly; not the least of its merits is that of its having considerable manurial value. Perhaps it may favour the development of fungi, as nitrogenous matter has a decided tendency that way. That, however, is given for what it is worth, and the gas liquor is certainly less objectionable than insecticides of a decidedly poisonous nature, such as Paris green, though that is a certain destroyer of insects; 1 lb. of the preparation mixed with thirty gallons of water syringed on the trees is certain to effect its object. It must not be used on trees that have the fruit advanced, and which will not have several forcible syringings with clean water after its application, and never where there are vegetables beneath the trees, and it must be kept from the hands of the operator, as it will be sure to find the least scratch, and produce serious ulcerations. Poisonous insecticides ought never to be trusted in the hands of the inexperienced—the most careful cannot be too cautious, and all should adhere as far as possible to the safest, leaving the dangerous to experts.

In last year's *Journal of Horticulture*, December 13th, 1888, page 532, I directed attention to the very troublesome red rust, or red fungus. In 1887 it was first noticed infesting a few

leaves of some trees against a wall under glass. Its attacks were, so far as we noticed, confined to the trees indoors, and had no apparent prejudicial effect on the crop. In 1888 the trees inside were much infested, the fruit as well as the foliage being seriously damaged, the trees being defoliated by early September. In 1888 the fungus attacked some trees on a wall adjoining the Plum house, and it spread in virulence proportionate to the distance—i.e., the tree adjoining the Plum house was as badly attacked as any in the house, and lost their leaves almost as early, the attack on the other trees on the wall being less as the distance increased, ceasing at the eighth tree, where there is a break from Plum to Pear trees. Other trees farther away were free from attack.

This year there has not been, as we anticipated, any mitigation, but rather an increased severity of the fungus attacks. In the house there was a determined attack of aphides, which succumbed very tardily to tobacco fumigations, and syringings were freely given to cleanse the foliage. Singularly there was no attack this year by the small green caterpillars, either in the house or on the trees outdoors that in the previous year were attacked by the fungus, but wherever the fungus appeared in 1888 aphides attacked in 1889. The fungus did its work so effectually that though we had a full crop of fruit it did not attain perfection. It partially ripened, but the fruits did not reach their full size, and had little flavour. Green Gage, for instance, had less than the quality of Orleans, and Jefferson and Coe's Golden Drop were less palatable than Victoria, in fact the dessert varieties were less saccharine than the usual culinary varieties. The foliage was cast shortly afterwards—i.e., after the premature ripening of the fruit, and whilst it remained with the fruit the spores of the fungus were shed in a very abundant minute powder, giving the upper part of the Plums a coating of black or deep purple. So light and minute is the dust that a puff of wind might blow it anywhere. The trees were defoliated for the most part early in September, not all the leaves falling, but those earliest and most severely attacked, and the characteristic is that the upper part of the trees lose the foliage soonest.

Trees on the wall outdoors attacked by the fungus in 1888 were still worse this year; even Victoria, which escaped in 1888, was defoliated when the fruit should have been ripe, for the ripening was not more than partly or badly done. The worst infested was Purple Gage, and Green Gage was so badly attacked that the fruit in one instance did not ripen, or only so indifferently that even wasps would not trouble to eat it, and they have been more voracious than usual this year.

The fungus has spread to other trees on walls over a hundred yards away. Being the first year of attack the foliage was still on the trees on October 21st, indeed fruit was on one tree—viz., Roe's Autumn; in fact the fungus pervades nearly every tree, and it is most effective on trees that have the most soft growth, as for example a Belgian Purple on a north aspect, though late attacked, was completely defoliated by early September. Albeit, some Damson and Winesour trees were equally as early, the fruit of the Damsons shrivelling on the trees.

This defoliation is strictly due to the fungus, for be the trees ever so clean an attack of the fungus is certain to cause early defoliation. That it is common to all the Plum tribe, and affects equally the wildling as well as those cultivated, whether in the open or under glass, I hope to prove to you by the specimens accompanying—viz., leaves of the Bullace taken from a tree in a shrubbery adjoining the garden, and which I consider is the parent of all the mischief in this case, others from trees against a wall, and some from trees under glass. There is no question, so far as I can make out, of the identity of the fungus. It spread from the Bullace to the Plum house, came, as I hinted last year, through the top lights in the late summer or autumn of 1886, infested the Plum house in 1887, extended to the trees on the wall adjoining in 1888, and over the whole garden in 1889. This points to the prevention of disease in Plum trees by the removal from the neighbourhood of Sloe, Bullace, and kindred trees, as both disease-producing insects and fungi live on such and spread to others of the same kind.

As the fungus lives inside the leaves it is not to be reached after the red spots appear. It takes nourishment from the leaves and prevents the proper fulfilment of their functions, but it opens in due course on the under side of the leaves, and then sheds its spores. Syringing with a solution of potassium sulphide effects a radical change in the persistence or life of the leaves, and it may effect the destruction of the spores. I am trying it, and am satisfied of its beneficial tendency. Then all the leaves as they fall are collected and burned, and this with the syringing with the solution of potassium sulphide, half an ounce to the gallon of water, not omitting the floor and border, and pointing the ground over in early spring before the young leaves burst from the buds is expected to mitigate if not insure freedom from attack. Perhaps it would be as well to employ softsoap solutions alternating with quarter of an ounce potassium sulphide solutions before the buds burst, and after

the fruit is set as soon as safe up to say the middle of June, or even until the fruit is so far advanced that netting it becomes undesirable. Water syringings alone have no deterrent effect, but rather contribute to the increased severity of the attack, as also does a confined atmosphere, which, however, may be due to the weakening tendency of heavy and continued syringing, similarly to a confined atmosphere preventing evaporation and the consequent softening of the tissues. Will some of our scientific friends kindly tell us if I am on the right track? Mineral matter, such as lime, with phosphor and sulphur and gas lime, is to be tried at the roots.—G. ABBEY.

BOUVARDIA CULTURE.

HAVING the privilege of serving a gentleman who prefers the Bouvardia to any other greenhouse plant, and having in former years grown them for Covent Garden, we have managed to attain a considerable amount of success with these plants here, and I am tempted to offer a few remarks on the subject of their culture to those who hitherto have not been so successful as they desire.

I do not propose giving any historical information, such being probably known to all, neither shall I mention any variety but those I have grown; for that reason some of the older forms and those introduced during the past year will not be alluded to. Supposing the reader to be already in possession of plants, or about to purchase them, they will now be in flower, and should be placed in a house where a night temperature of from 45° to 50° is maintained, with a rise of 10° or 15° by day. In cold weather a rise of 10° is ample, allowing, however, an additional 5° in bright weather. In this house they should remain until they have done flowering. Water should be given as required, using weak liquid manure at each alternate supply. When flowering is completed they may be stood under the stage in the same house, sufficient water being given to keep the wood plump and no more. It is customary in some gardens to dry them off, similar to Fuchsias. I did it once, and lost several plants—in fact, two or three varieties were lost altogether, and as I had to make the latter good at my own expense I received a lesson to be remembered. About the second week in March our plants are cleaned and pruned. Plants from last year's cuttings are shortened back to 4 inches from the pot; those a year older are cut back to within a couple of inches of where pruned the previous year. Older plants are treated in the same way—that is to say, all growths are left 2 inches longer every year. The plants are then placed in a vinery that is always started at that date, and kept regularly supplied with clear water, syringing them in the mornings and when closing the house. When the plants are breaking well into growth they are repotted. The soil used consists of loam two parts to one each of peat and leaf mould, with sufficient sand to show plainly through the soil; with the exception of the leaf mould, which should be passed through an inch sieve to free it from sticks, the compost should be broken up by hand, and all wireworms looked after sharply. I am no advocate of starting them in small pots and subsequently placing them into larger pots. We have no time in this part of Ireland now-a-days for such proceedings, and the planting out method not proving satisfactory with me it has been abandoned, and one potting a year is all the plants have. About half of the old soil is carefully picked out, perfectly clean pots one size larger than those previously occupied are carefully crocked, covering the crocks with moss, then a small quantity of the roughest of the compost over the moss, followed by a handful of half-inch bones, and the plants firmly potted with the aid of a rammer for the largest pots at the same level as they were before. They are then returned to the vinery, and syringed three or four times daily until about the fourth day, when they are all watered through a fine-rosed pot. After this syringing is only done twice a day in the morning and at closing time.

If desirous of increasing the stock, as soon as the growths are long enough cuttings are inserted thickly in 4-inch pots, and plunged in a propagating case until rooted, when they are potted singly in thumbs, and returned to the case until established. They are placed in the vinery with the older plants; when the roots are well through they are shifted into 4-inch pots to flower in. As soon as rooted the point should be pinched out, stopping them afterwards at every second joint until the end of June, when stopping is discontinued. When no cuttings are required the old plants are pinched as soon as possible after two joints are made, continuing in this way until the end of June. The plants are removed from the vinery early in May to cold pits and frames, covering with mats at night; the covering is reduced gradually until by the end of the month none is used. From the commencement of June more air is gradually admitted both night and day, while during July and August the lights are taken off entirely; should, however, a long spell of wet weather set in they are placed on until fine weather returns once more. During September the

quantity of air by day is daily reduced, and the frames closed at night; at the end of the month they are taken into the greenhouse, when they commence flowering, and continue to do so until well into the new year. The syringing is done twice daily in fine weather until the plants are housed, when it is discontinued. Before taking the plants to the greenhouse they are staked and tied; one stake only is used, to this the central growth is tied, and all remaining growths are slung to the stake with slender strands of raffia.

Good varieties are Alfred Neuner, double white; Bridal Wreath, blush; Vreelandi (Davisoni), white; Dazzler, bright scarlet; elegans, scarlet; flava, yellow; Humboldti corymbiflora, beautiful snow white, scented; Maiden's Blush, rosy blush; President Cleveland, intense scarlet; President Garfield, double pink; Priory Beauty, pale rose; Reine des Roses, rose pink; The Bride, pure white; and Victor Lemoine, double reddish purple.—HANDY ANDY.

FRUIT JOTTINGS.

ON page 352 a few notes were given as the result of a visit to Sawbridgeworth, and to those the following may be added as the result of the same journey.

ORANGES FOR USE AND PROFIT.

Of the many interesting features in Messrs. Rivers & Son's establishment the house devoted to Oranges and allied plants is certainly not the least attractive. Early in the present century orangeries were much more frequently seen in gardens than at the present time, though in some old establishments the buildings still remain generally employed as conservatories or stoves. Unfortunately they are in too many cases heavy dark structures quite unfitted for plants of any kind, and particularly so for Oranges, which may in a great measure have led to the discontinuance of their culture. The enormous increase in the importation of Oranges, however, has been the chief factor in this matter, as when the fruit could be purchased three or four a penny on the hawkers' barrows it seemed ridiculous to give the plants valuable space under glass. Another point, too, is that the large old trees formerly grown in immense tubs occupied a considerable amount of space, and when they became weakly with age and not too liberal treatment, rarely flowering, still more rarely perfecting eatable fruits, and infested with insects of divers kinds, they were neither ornamental nor profitable. In some continental gardens the old fashioned orangeries have been retained and are still employed for their original purpose, notably at the King of the Belgians' Palace at Laeken, where, under the charge of Mr. Knight, are some of the largest healthy specimens we have ever seen. They are only, however, maintained in good health by very liberal treatment, frequent top-dressing of manure, and constant attention to keep them free from insects; they necessitate a great amount of labour, especially in removing them every summer to the open air and back again in autumn to the orangery.

A large proportion of the varieties formerly grown are comparatively worthless, and this combined with imperfect ripening rendered them a very unsatisfactory substitute for the better selected imported fruits. No doubt they were frequently chance seedlings raised here that had never been duly proved by comparison with others, and after they had been grown for several years there was a natural reluctance to destroy them. It has, however, gradually become known to a few cultivators in this country that some of the varieties now grown so extensively in the West for importation to this country are greatly superior to others, and further that when taken in a properly ripened condition from the tree their flavour is much richer and the quality better in all respects than the imported fruits that are necessarily gathered before they are ripe. Such home grown fruits have occasionally been placed before the Fruit Committee of the Royal Horticultural Society, and invariably with the result that the members have been surprised at their quality.

Messrs. Rivers & Son have given their attention to these plants for many years, and the result is that they have a light span-roofed house filled with moderate sized trees in small pots, representing a series of carefully selected varieties. Apart from the ornamental value of well grown Orange trees, as their fragrant flowers, golden fruits, and rich green foliage are unsurpassed, they are exceedingly useful as affording an addition to the dessert that all can appreciate who have once tasted thoroughly ripened fruit from under glass. Some of the best of the St. Michaels varieties are Sustain, having a peculiarly delicate flavour and abundant juice; St. Michaels, with a very thin fine rind and of excellent flavour; Exquisite, one of the same type, differing slightly in habit, foliage, and the form of the fruit; and Silver, one of the best of the group. In the Malta

varieties, the Blood, Oval, and Pernambuco Orange are all good. Several varieties of Lemons and Limes are also grown, and the lighter yellow colour of their fruits contrasts beautifully with the Oranges.

Culturally, one important point must be noted, and that is the stock upon which they are grafted, a matter which does not usually receive the attention it demands. It has been the custom to raise seedlings indiscriminately from any Orange pips and then graft upon these, but this has been proved at Sawbridgeworth and elsewhere to be as erroneous as any haphazard method of action can be. After trying a variety of stocks the common Lemon has been found to be the best to promote early bearing with a compact habit and fine fruits. This accordingly is now the practice adopted, and I understand that in Australia and Florida, where Oranges have been so largely planted in recent years, the same course is followed. Then for soil a good turfy loam is employed with sufficient sand to render it porous; thorough drainage is provided and abundance of water supplied both to the roots and over the foliage. Beyond the maintenance of a genial and even temperature nothing is requisite except an occasional thinning or shortening of the growths and close watching to see that the plants are free from insects.

STORING FRUITS.

All who are concerned with preserving the supply of Apples and Pears as long as possible know full well the difficulties there are to contend with. Some advocate placing the fruit upon the open shelves or staging in the fruit room; others employ straw, hay, or paper as an absorbent material, upon which the fruits can rest, each having its special recommendations and disadvantages. The great desideratum is to have a material that is quite devoid of odour, as the flavour of fresh fruits is very readily affected by anything of a foreign character. At Sawbridgeworth, after many experiments, ordinary burnt earth has been adopted as the best substance for the purpose, and it is placed in a layer an inch or two deep over slates. A small span-roof house has the roof thickly thatched in the place of glass, leaving only spaces at the ventilators for the admission of light and air. The path in the centre has a well edged bed on each side, and these are devoted to storing samples of the principal varieties of Apples and Pears.

SEEDLING FRUITS.

The Sawbridgeworth Nursery is not only a fruit-growing establishment, but it is also one in which fruit-raising has been carried out with remarkable success for a long period. This is chiefly due to the fact that it was commenced a considerable time ago by the late Mr. Thomas Rivers, who derived much pleasure from what subsequently proved a very profitable occupation. Thousands of seedlings were raised of Peaches, Nectarines, Apricots, Plums and Pears, many of which resulted from the careful crossing of approved varieties that were likely to produce the best returns. In all cases records had to be kept, and the seedlings watched for years before it was known whether they would prove distinct or useful additions to the lists. They were crossed not only with a view to the improvement of quality, but also to extend the season during which such fruits could be gathered either under glass or out of doors. The last is an important matter, and much has been accomplished in that direction amongst Peaches, as already noted. In one of the editions of "The Orchard House" Mr. Rivers had some remarks on this subject. "To give the reader an idea of the pleasing uncertainty of raising seedling fruits, and that a stone from Early Beatrice may produce an October Peach, I may mention that a large Peach raised here from the Early York Peach some years since, is a fine late sort, ripening early in October; the cultivator may also expect Nectarine trees from Peach stones, and Peach trees from Nectarine stones. Plums and Cherries vary to a great extent when raised from stones, and are most interesting. They in common with Peaches, Nectarines, and Apricots should be grown in pots in the orchard house, where they will commence to bear at about four years old. A hard hearted cultivator must select the seeds for the production of new varieties; he must choose the finest and best flavoured fruit, as no seedlings must be raised from inferior fruit." He observes elsewhere, too, with regard to Peaches that twenty stones from the Royal George Peach will not produce two alike in all characters, while Noblesse and some of the yellow-fleshed Peaches are reproduced nearly true from seed. The most difficult trial is after growing seedlings for five or six years to have to discard so many, yet this has to be done unflinchingly, as it is obviously useless keeping varieties that show no advance on those ready known, and, of course, in some instances they are even inferior. Still, the selected seedling Peaches, Nectarines, and Plums sent out from Sawbridgeworth are more numerous than could be expected. Thus of Peaches twenty-six are of proved merit, of Nectarines nineteen have taken a similar position, and of

Plums nineteen have also been secured, the latter including such thoroughly useful varieties as Early Rivers, The Czar, and Monarch.—POMONA.

ASPARAGUS.

THE most general mode of forcing this vegetable is by making hotbeds in the usual manner about 3 feet high of well prepared manure. It is important that the bed be well prepared, as the roots are very quickly injured by a strong heat, especially when accompanied with much steam. The manure should have repeated turnings, so as to allow all rank steam to escape previous to being made into beds. When these are finished the frames and lights may be placed on, leaving them so until the bed has attained a regular heat; after this tread the surface evenly.

The roots may be from three years' growth upwards. These can be lifted from the beds in the garden, exercising great care in this operation, as the roots are very brittle. Previous to placing these on the bed it should be covered with a few inches of dry light earth, spreading it evenly, then commence at one end, and place the roots close together in a regular manner, keeping them level and the crowns uppermost. When the frame is full these may be covered with some fine light soil, filling all spaces between the roots, which may be covered to the depth of 4 or 5 inches.

There is not much likelihood of the heat becoming too strong if the manure has been properly prepared. However, should this take place the lights may in fine weather be taken off, which will allow the rank heat to escape. When the buds begin to grow air should be admitted, and after they appear above ground the lights may be removed for a short time on fine days. Air should be admitted as much as possible, or the shoots will be drawn up weakly without colour or flavour. If the bed becomes too dry water must be given with a fine-rose pot, using water of the same temperature as the bed. The heat will be sufficient if the bed keeps about 50° at night and 60° by day with the sun heat. Should it, however, fall below 45° linings must be applied. It is advisable to keep the temperature from 50° to 60° throughout. If wanted for succession the beds may be made up and planted at intervals of three weeks.—A. G. FRAMPTON.

PRUNING SHRUBS.

THE proper time to prune or cut back trees and shrubs is a question often asked in the Journal. If experience warrants anyone giving an opinion on the matter I do not think that I need be afraid to state mine, as we annually do much of this kind of work. Our pleasure grounds extend to between 30 and 40 acres; nearly the half of this area is covered with trees and shrubs, and many cartloads are cut from them every year. We cut them with two objects in view—the first to keep them in shape, the second to keep them within due bounds.

In cutting the shrubs into shape great care should be taken that this is not overdone, as nothing detracts so much from the beauty of a choice tree or shrub as cutting it into a formal cone. Our rule of cutting into shape simply consists in removing one of the leaders when two are forming, or cutting a few more points from one side than the other as the growth demands. In doing this we endeavour to cut without leaving any signs that pruning has been done. This applies particularly to single specimens on lawns, and isolated shrubs which stand apart from or above others in groups.

Cutting to keep shrubs within bounds is generally practised on Yew and other hedges, and on shrubs growing close to walks and flower borders and also in clusters together. Hedges may be clipped smooth like the face of a wall, but Rhododendrons and similar evergreens should be cut with the knife only, and that just to remove the intruding points, leaving no stumps in a prominent position where only a surface of leaves or leaf-bearing shoots should be seen. Apart from this, however, the form and style into which trees and shrubs are cut will follow the owner's taste in many instances.

The time of cutting is of very great importance. In situations where the winters are mild and cutting winds do not usually prevail in the spring every kind of tree and shrub that will grow unprotected in the open air may be safely cut, clipped, or pruned from the beginning of November until the end of March. Cutting before November when the shoots may not be matured often causes them to die-back more or less from the wound, and to cut them when growth begins in April or during the growing season injures many of the more tender sorts. In districts where the winters are generally frosty and severe only shrubs of the very hardiest description should be pruned until the latter end of March,

and by that time it is, as a rule, always safe to prune any kind of shrub as freely as is required.

The prunings of all kinds of shrubs cannot be more profitably disposed of than by burning them; the ashes make an excellent manure for the kitchen garden. They suit all kinds of vegetables, and when mixed with a little soil they are excellent for covering Onion and other seeds.—P.

ORCHID NAMING.

THIS subject is now under discussion, and the Committee appointed by the Royal Horticultural Society will no doubt do their best to remove some of the anomalies and inconsistencies of the present system, or want of system. In connection with it there are, however, two or three points upon which I wish to express an opinion, and I should like to see others do so with the same object in view. First, as the intention obviously is to deal with garden nomenclature only it is evident that the subject ought to be submitted to horticulturists and be determined by them. Botanists professedly disregard the numerous varieties which are prized in gardens, and therefore it does not come within their province at all; farther, it is an unfortunate and deplorable fact that a discordant feeling exists between them and horticulturists, and it has always been a most difficult matter to effect a combination of the two that would work harmoniously. This feeling is undoubtedly less than was the case at one time, and broad-minded men are conscious of the advantages arising from the mutual assistance of theoretical and practical knowledge; still, it is quite as inadvisable for botanists to dictate to horticulturists in purely garden matters as it would be if the case were reversed. Any system of nomenclature proposed by the R.H.S. for Orchids or other plants as occupants of gardens should, to ensure anything like general support, be horticultural and not botanical rules.

If the botanists adopt one system of nomenclature, and it is found to be suitable, there is however no reason, as far as I can see, why the horticulturists should not name their plants in the same way if they wish to do so. On the other hand, it is desirable to make some distinction between introduced wild plants and those raised under cultivation, and this is most readily effected in the ordinary way by the adoption of popular names for garden plants where the differences are very slight and where the plants admit of rapid increase either by seeds or cuttings; what is termed botanical names, or those compounded from the Latin and Greek, being reserved for introduced plants. There is very little difference of opinion on this matter, and if this is all that the Committee has to determine it will no doubt soon complete its work. It is easy to separate introduced and home grown plants into two clearly defined groups, and it seems preferable to rest any distinction in nomenclature upon this than upon doubtful characters.—PRACTICAL.

ODONTOGLOSSUM VEXILLARIUM.

IN many gardens only two divisions exist in which Orchids are grown—one cool and the other warm. It is therefore often difficult to give plants that require an intermediate temperature the exact treatment they need during the winter. If grown too warm the above-named Orchid quickly assumes a sickly appearance and becomes a prey to yellow thrips. This is not all; growth is forced much more quickly than is desirable, and the foliage in consequence is weak and incapable of supporting itself. Under cool treatment the plant goes back rapidly, and one evil is equally as bad as the other. Since we have maintained a higher temperature in the Odontoglossum house we have not experienced so much difficulty. At one time we had hot-water pipes only down the centre of a narrow span-roofed house for Odontoglossums, and the plants on the north side suffered severely at the back of the bed. This led to two 1-inch pipes being taken off those in the centre and arranged along the ventilators on the north side. These have acted admirably, and close to the central division we have now the exact place for *Odontoglossum vexillarium*. The night temperature ranges from 55° to 60°, according to the weather, and the plants are at home. Until this arrangement took place they were removed early in November to a plant house, where an average night temperature of 55° was maintained. It is a mistake to keep them either too warm or too cool for the mere sake of keeping all the

Orchids together when more suitable treatment can be accorded to them in some other structure that may not be devoted to Orchids.—N. G.

DENDROBIUM FALCONERI.

WHEN well grown this *Dendrobium* is one of the finest in its genus, its free graceful habit and abundant richly coloured flowers rendering it a charming plant in any warm Orchid house or stove. It is true some found a little difficulty in its cultivation, but the chief point is no doubt, as with other species, to insure the growths being well matured, with the provision of a light airy position. Mr. B. S. Williams says, "During the growing season it likes a good supply of water; but after it has finished growth, which is by autumn, it should be kept rather dry till it begins to show flower, but must never be allowed to suffer for want of water, as it frequently grows during the winter months." This exactly accords with my experience, and it is certainly not nearly so difficult to

FIG. 46.—DENDROBIUM FALCONERI.

flower *D. Falconeri* every year as some other species, particularly those from Australia.

One of the attractions of this *Dendrobium* is the great size of the white lip and the wonderfully rich colour of the broad central crimson purple spot; the sepals and petals also are frequently tipped with purple. The central blotch is usually surrounded by a zone of orange, and the tapering part of the lip is frequently coloured like those of the sepals and petals. Several varieties are cultivated, one of the finest giganteum being that represented in the woodcut (fig. 46). There is another named *Jacksoni*, which is so distinct that it has been regarded by some as a species. It seems, however, to be simply a form of *D. Falconeri*, but differing in its leading characters. The flowers are usually smaller, with shorter sepals, petals, and lip; the latter more of a golden hue and wanting that peculiarly rich crimson spot so much admired in the ordinary *D. Falconeri*.—B. W.

CATTLEYA LUTEOLA.

THIS is a very distinct species, and also very rare; in colour it somewhat resembles *C. citrina*, but bears no other similarity, and we cannot do better than quote Sir Wm. Hooker's description, which was prepared from a specimen in the then celebrated collection at Tooting:—"Our plant has an annulated branched rhizome about as thick as a duck's quill sending down from beneath a few thick fleshy fibres, and upwards from the short branches elliptical, quite smooth, and compressed pseudo-bulbs, which bear one leaf, and while young are enveloped in a large sheathed, membranous, striated, sheathing scale. These increase in age, and eventually become oblong, nearly terete, and sulcated; leaf about 3 inches long, thick, succulent, dark green, elliptical, veinless, with a deep notch at the apex. From the base of this leaf, at the top of the pseudo-bulb, arises the peduncle scarcely 2 inches long, enveloped entirely in a compressed membranous sheath, slit open on one side, four, five or more flowered; flowers racemose, pale lemon yellow, small for the genus; sepals and petals uniform, $1\frac{1}{2}$ inch to 2 inches at the most long, oblong lanceolate, obtuse, a little waved, all spreading; lip about as long as the segments of the perianth, three-lobed, velvety within, the side lobes elongated, incurved, meeting over the column, and forming a kind of tube; the terminal lobe broad, almost orbicular, crisped and ciliato-dentate at the edge, column much shorter than the lip, semiterete." It blooms during October and November. Native of Brazil. 1853.—T.

TREATMENT OF SOILS AND MANURES
AND CROPS.

I HAVE given the principal constituents of several manures. I will proceed with the various crops, the sowing, planting, and the preparation of the soil and the plots that they ought to occupy. I ought not to pass over two very valuable manures that often come within the reach of the gardener—viz., the deposit of a pond or the bed of a river. I would strongly recommend its use in the garden. The river deposit is very rich in all the mineral elements, and the pond, while also rich in them, still contains more organic matter, and both can be used upon any soil with great advantage. Road scrapings ought also to be used, particularly on heavy land. The refuse from ditches should be reduced to ashes before being used. To put my recommendations in my first article in a better light I will give what I have to say in as simple and practical way as possible.

CAULIFLOWERS.

The exact time of sowing must depend upon the locality; the 1st of August is a good time for the north, the 15th to the 25th the midlands, while the end of the month is suitable for the south. Sow the seed on a good open border. The soil does not require a special preparation; it ought nevertheless to be well dug and rammed down firmly, the seed sown broadcast, raked in, and protected from the birds.

One of the plots left vacant by Onions, Peas, Beans, or Celery should receive a good dressing of manure. That vacated by Celery will require less than the others; provided it has been well done a simple dressing of lime will suffice, and in the other cases it ought to be applied with the manure. In both cases incorporate the manure and the lime well with the soil, as the greater the diffusion the more their value is enhanced; in all cases trench the ground. I would sow Walcheren for this district the second week in August; as soon as they are large enough plant them out in the prepared piece of ground at half the distance required. In the spring thin to the proper distance and fill any of the vacancies left by the frost. These plants will form heads in May and June, according to the district. A good system practised in some parts is to plant a score in a handlight and transplant in the spring. The seed bed should not be destroyed till the plants are safely on the way, as any blanks can be refilled. Market growers and others around London plant Cauliflowers in a triangle, and place bellglasses over them. I recommend this in all cases where very fine early heads are required and glasses can be had. Allow the plants plenty of light and air all round, then they will not require transplanting in the spring. The bellglasses should be either tilted or taken off as the weather permits. It must not be lost sight of that the constituents of the Cauliflower are 21 per cent. of sulphuric acid, 12 phosphoric acid, 20 soda, 11 potash, 20 lime, and that the nature of the soil is the index to its treatment as regards the manuring. If it is calcareous no lime is requisite, but if it is full of humus then apply lime. The finest Cauliflowers I ever saw were grown on a piece of ground where a quantity of night soil had been used together with some blood prepared in lime.

At the beginning of February sow in gentle heat Veitch's Early Forcing Cauliflower. This is one of the finest varieties. It

starts away readily when planted out, and seems to rejoice in the different changes, and races hard to come in before the autumn-sown Walcheren. When large enough prick them out or pot them, and stand in a cold frame. If sufficiently hardened and the weather permits plant out in the beginning of April on a good border, and another batch at the end of the month, on an open quarter of the garden, to form a succession. At no period should they be allowed to suffer either in the pots or boxes, and if supplies of cesspool water are given and they are hoed freely a good crop will be the result.

The piece of land vacated by the crops already mentioned should be immediately manured and trenched. If no "snatch crops" are wanted sow with anything that will spring up, and grow during the early autumn months, and in the spring turn this in. If plenty of manure is at disposal, or a slight dressing of lime can be dug in which will decompose the green herbage, so much the better. Celery ground will not require trenching for Cauliflowers. The various sowings and plantings must entirely depend upon the requirements of the family. I would sow Walcheren upon a warm border at the beginning of March; these will come in for planting out in April, and for cutting in July, and August, and September. In April sow Veitch's Autumn Giant or any other variety for early autumn cutting at the end of August, in September, and beginning of October; Veitch's comes in excellently for this sowing, and would recommend it to those that have not tried it. During the middle of May sow Autumn Giant for late autumn work. Where the first Peas are off in May or at the beginning of June it is not necessary to keep a plot of ground for this planting of late autumn Cauliflower. Plant out during the end of June, always selecting showery weather if possible, but if not able to do so puddle the plants in and keep the ground well hoed and watered until they are established.

One thing I ought not to pass over, that is the necessity of looking after the late Autumn Giant. It protects itself better than any other, but when pulled up in frosty weather with good heads and laid in a shed out of the way of the frost they will keep a month or six weeks and be none the worse for table use. Those not headed enough should be placed in a frame, taken up with as large a ball as possible, and if protected they will form good heads in January. Always plant 2 feet apart for a crop, and when trenching turn the manure in at the bottom. If the subsoil is very poor only bastard trench, and throw a few spadefuls over the surface, so as to gradually improve its depth; lime has a wonderful effect upon bad subsoils.

CABBAGES.

Cabbages are almost always to be had in gardens in some form or other, but they are not all equally good; the larger sorts are more animals' food than man's, of the present age at any rate. The various plots of ground mentioned in the treatment of Cauliflowers, together with the plots left vacant by Leeks, Potatoes, Lettuces, or Kidney Beans, are suitable for Cabbages. They like the good ground, and as the ash constituents of the Cabbage are identical with those of the Cauliflower, Broccoli, Brussels Sprouts, Savoy, and Kale, the analysis given will suffice for all. The ground should be supplied with lime if that is thought to be deficient, and in no case allow the doubt to go against the Brassica. As regards manure they more often suffer from too little than too much, and if the soil is well prepared there will be no club or ambury. In this district club is much against the gardener securing good Cabbages and Cauliflowers, and The Grove kitchen garden particularly so, yet no cases of clubbing have come under my notice. I account for this by well preparing the ground and giving the plots planted with the Brassicas a good coating of blood mixture prepared with lime and cesspool water in a mound of soil.

At the end of July or the beginning of August sow Veitch's Earliest of All for early spring cutting. I have grown this sort, and it has given me great satisfaction. Sprinkle the seed bed with soot and lime to prevent the attack of insects, and in September plant out some in a good open part of the garden. Nothing is gained by planting in close borders or corners; of course, too exposed parts must not be chosen. The plants can be planted twice as thick as wanted, thinned in the spring, and fill all vacancies caused by the frost. Keep the soil from getting battered down by occasional hoeing. This must be done, too, in the spring, and if a little soil can be drawn up to them so as to secure them against the winds they will make greater strides. I believe in clearing off these as soon as cut, or anyhow as soon as the next can follow. Some sharp winters do not leave any to be cut, and to prevent disappointment it is well to prick out fifty or a hundred plants as late as possible in a frame, leaving the lights off in all weathers except when frosty. If a two-light frame can be spared plant one light with some from the August sowing, and during September

sow the other light with Ellam's, to come in for planting out as a succession to the early. Those pricked out in the frame may be planted out in March or the beginning of April in small hoed trenches about 2 feet apart. Plant out seedlings from the frame in April as a succession. During this month sow the principal crop. Each one has his favourite sorts, and it does not matter so long as it is a good one and suits the cook.

A good quarter of the garden ought to be chosen for this crop. Trench deeply and keep all the plants well watered first with clear water, then with liquid manure. The plants can be drawn from the seed bed at different periods to fill any small corner or border as a safe way of always having some good Cabbages to cut; and it is always best to have a few to having a glut at one time and none at another. If there are any more Cabbages than wanted they can be used for the pigs.

Sow seed and plant again in May. I would sow Little Pixy or some small form to plant out after the summer crops are being cleared off. They will come in at a very useful time after most of the Peas.—G. A. BISHOP.

WINTERING CARNATIONS.

It is not so difficult to winter Carnations in safety as it was some years ago, as the plants now cultivated are generally of a more robust constitution than they were formerly. As a matter of course, I am treating of the fine named varieties that are layered in pots. If my own plants can be taken as an indication of the general experience I should say that layers have done well, as all mine appear to be rooted, and they are clean and robust. I am more and more convinced that there is nothing like early layering, and the sooner it can be done in August the better. Much depends upon whether the "grass" is sufficiently ripened, and this is a matter of the first importance, as many disappointments result from layering shoots which are too young and sappy.

The time to repot the rooted layers has come. Time was when a kind of prejudice existed against bushy plants, and when they were taken from the sides of the pots, after carefully severing them from the parent plant, the practice was to remove all decaying foliage and such small side shoots as had been put forth, the theory held being that a clean stem was always preferable to a bushy plant. In potting, a strong plant can be placed singly in a 3-inch pot, or two plants in a 4-inch pot, using a fairly stiff compost made up of good yellow loam, some leaf mould, and sand. It is better to have the compost a little heavy than too light, and the Carnation likes firm potting. Do not bury the plant's too deeply, keeping a clear stem above the soil, and they should then be placed in a cold frame for the winter.

An ordinary garden frame will do, for the Carnation is a thoroughly hardy plant, and needs protection from wet rather than from frost; but a dry base is essential to keeping the plants in perfect health during the winter. Dryness about the earth on which they stand and about the pots has a material effect on their well-being. At the Royal Nursery, Slough, the frames employed for wintering Carnations in pots are shallow, so as to have the plants near the glass, and the bed on which the pots stand is made of dry brick rubbish, upon which is laid cinder ashes, enough to make a good level surface. When placed here the newly potted plants can be shaded from bright sunshine, and be kept a little close for a few days until they become established. Then air can be admitted freely, and if the lights are drawn off and the plants have the advantage of a genial autumn shower they are benefited thereby, but drenching by heavy showers should be avoided.

Some growers of small collections did make a practice of plunging the pots up to their rims in cinder ashes during the winter. This may be still desirable in the case of any delicate growing varieties; but cocoa-nut fibre can now be employed, as it is cheap and easily procured. During November and December but little water will be required, and when it is given it should be through a fine-spouted watering pot, pouring the water gently on the surface, and taking care not to wet it in any way if it can be avoided. Water should be given only when the air is dry and bright, so that the lights can be removed and superabundant moisture expelled. A mild shower will be beneficial, only that when close muggy weather follows it is difficult to get rid of the moisture which hangs about the foliage.

Let it be remembered that the Carnation is a thoroughly hardy plant, and will endure a great amount of frost. The charge is sometimes brought against those who grow their plants in pots, that by doing so they coddle them, and make them delicate and tender, robbing them of that robust constitutional vigour peculiar to the plant. This is ignorantly made by those who know but little or nothing of the thoroughly hardy way in which the plants are grown all through the year. By growing them in pots the cultivator

has his plants under perfect control, and they run none of the risks which threaten those grown in the open air. I grow inferior varieties in the open, but all choice ones of high quality in pots; but they are as hardy as those which pass the winter in the open soil. As a matter of precaution it is well to cover the frames closely when severe weather prevails. In dull, foggy, and misty weather the lights should be so tilted as that a current of air can pass about and over the plants, and whenever it can be done let the lights be pulled off. During the winter the plants should be examined at times, any decaying foliage cut away, and the surface soil stirred.

March has been described as the most trying month, for then dry and parching winds prevail. By that time the plants are beginning to move, and will require more water when the weather is open and drying. While cold winds blow they should not play upon the plants if it can be avoided; and it is well, therefore, to open the lights opposite to the quarter whence the wind is blowing. At all times cleanliness is of the first importance.

I am a decided advocate for early transference to the largest pots. Our springs are now generally late and retarding, and as a good start is of great importance in the matter of having fine blooms in July early potting is desirable. I know some growers who begin early in March, if not before. A good deal depends upon the plants being well established in the pots in which they have been wintered. If they are filled with roots then repot into those in which they are to flower as early as possible, and do not overpot, and at all times adapt the size of the pot to the constitutional vigour and necessities of the variety.

Those who leave the ordering of Carnations and Picotees until the spring, when the plants are frequently taken from the pots in which they were layered, cannot expect they will produce such fine blooms as those potted in the autumn. I have known orders for plants sent to a nurseryman in April, at a time when the plants should be in the pots in which they are to flower.—R. D.

CYPERUS ALTERNIFOLIUS.

THIS is an easily grown plant that anyone having a greenhouse should cultivate, for none is more accommodating, or withstands indoor treatment better, unless it be the *Aspidistra* or *Ficus elastica*. A healthy well-rooted plant can be kept indoors for weeks without change if duly supplied with water, of which it requires abundance, and the foliage occasionally syringed or sponged in order to keep them free from dust accumulations. It is one of those plants that are suitable for use in gas-lighted rooms, the atmosphere of which proves fatal to so many that are cultivated in greenhouses. It is of easy propagation by division of the roots or by striking the crowns. The former is the quicker mode by which large plants are secured, and perhaps the more easy, but for useful decorative material in small pots the method of rooting the separate crowns will find most favour. They may also be raised from seeds.

It is only recently I have found how easily they may be rooted in water. The heads, no matter whether they are seed-bearing or not, if taken off and thrown into a tank of warm water will within a very short space of time form new growths and roots simultaneously. These shoots may be allowed to extend about an inch long previous to placing them into small 60-pots, which, when favoured with an intermediate temperature, not necessarily air-tight, roots and tops very soon become active. Heads that contain matured seeds may be treated as cuttings and placed at once into small pots; but germination is hastened in this case by their being kept air-tight.

Just now our plants are in active growth, and many of the older leafstalks assume a worn-out appearance consequent, presumably, on the energies of the plants being directed into other channels in the formation of new growths. These old beds make suitable material for increasing the stock, and if these are rooted now they will most likely make useful little plants by the early spring months for standing in small vases on the table. Probably the above remarks may help a correspondent to solve a difficulty with a variegated *Cyperus*, as it is said the leaves are turning brown. I should advise him to cut them off, and if warm water in a tank or tub is not to hand they may be placed in saucers of water and put on the hot-water pipes until rooted.

Rich soil in potting is not required, and for the variegated form it should be strictly avoided, for if this is applied the variegation will be replaced by its green or original colour, which is afterwards difficult to restore. Loam and sand should form the greater bulk in the compost prepared, but if of a heavy nature this might be corrected somewhat by the addition of a small quantity of peat or leaf mould.

Water they require frequently when the pots are full of roots, and in the green sort occasionally an application of liquid or artificial

manure may be given with benefit; but abstention must be practised with the variegated one, or the result will be similar to that produced by rich soil. Like many variegated plants starvation is required in bringing them up to the best standard of excellence, and this quality is still further assisted by their being restricted in root space.—W. S., *Frome*.

EVENTS OF THE WEEK.—The Shows have commenced in earnest, and in the present week a large number will be held. The principal announced are as follows:—November 8th, Crystal Palace; November 9th, Kettering; November 11th, St. Neots and Surrey; November 12th, the National Society's Show at the Royal Aquarium, Westminster, Kingston-on-Thames, Wells, and Exmouth; November 13th, Bournemouth, Torquay, and Croydon. Several of these are two-day shows.

— WE learn that the Lord Mayor of London, Alderman J. Whitehead, who has devoted so much attention to the fruit question recently, has been created a baronet. The following additions have been made to the Fruit Fund now being raised:—Mr. H. R. Williams has given £25, Mr. George Cutt £25, Sir William Ogg £25, Colonel North £25, and Mr. C. J. Leaf £10. The fund now amounts to about £1500.

— **EXHIBITIONS IN LONDON.**—We learn that a series of horticultural shows will be held in the Royal Aquarium, Westminster, next year under the direction of Mr. William Holmes of Hackney, at which liberal prizes will be offered for Forced Plants, Florists' Flowers, Hardy Plants, Bulbs, Fruit, and Vegetables. It is intended to hold a show in each of the following months—March, April, May, June, July, September, October, and November. The arrangements are not completed, but particulars of the special features at each exhibition will shortly be announced.

— In the report of KETTON HALL GARDENS, which appeared on page 101, reference was made to Mr. Hopwood's Orange-growing estate in Florida. Mr. W. H. Divers informs us that he is going for a few weeks to inspect that estate, and that his foreman, Mr. John Tunnington, will take full charge of the Ketton Hall Gardens during his absence.

— At the monthly meeting of the TEDDINGTON HORTICULTURAL DISCUSSION SOCIETY last week, Mr. E. H. Douët in the chair, the cultivation of the Tomato formed the subject of a profitable discussion. The initiative was taken by Mr. D. Anderson, the well-known nurseryman, and Secretary of the Society, and most of the members present had some useful experiences to relate and suggestions to offer concerning the successful growth of this important plant.

— **TRADE ANNOUNCEMENT.**—Under the title of the English Fruit and Rose Company (Limited) a company has been formed to purchase from Mr. J. Cranston the King's Acre Nurseries, Hereford, and to grow fruit, Roses, and other flowers for market. The capital is £30,000 in £1 shares, 20,000 being now issued.

— **A GOLDEN ROD WEDDING.**—An American correspondent sends an account of a recent event in Rhode Island, which is called a Golden Rod wedding, because the Golden Rod was used for decoration. "It was put everywhere, upstairs and down, on the steam radiators, the mantel-shelves were banked up to the ceiling, and no other flower was to be admitted except rich, many-coloured Asters, white ones being prominent in the arrangement. The bride stood in a large bay window under the arch, the whole resplendent with Golden Rod; a marriage bell of the same flowers hung above her head."

— **BERRY-BEARING PLANTS.**—Whilst the year is quite exceptional on account of the openness of the season thus far—and it is November—Dahlias, Asters, Sunflowers, and other gay garden graces are in all the freshness and richness of the early autumn; it seems also to have been an exceptionally good year for most of the ornamental berry-

bearing plants. Walking through Dickson's nurseries at Chester—and their grounds are bleak and exposed—one day last week I was much struck with the wonderful profusion of beautiful berries upon the Pernettyas in their ornamental garden. I have never seen their collection equalled, and the large border planted with shapely plants of the different hybrids was simply a mass of many coloured beautiful heads, and one of the most effective sights I have seen for some time past.—HORTUS.

— YOUR correspondent, "J. L.," may like to try the ZONAL PELARGONIUM MRS. LEAVERS, which I have found an excellent bedder, and the colour of the bloom, a beautiful bright rose pink, is very effective.—MATT. HODGTON, F.R.H.S.

— **CROSS FROM ROSA RUGOSA.**—M. Bruant, the French Rose grower, who is hybridising *Rosa rugosa*, and who originated the variety Madame Georges Bruant, a cross between a Tea and *R. rugosa*, has this season brought out another hybrid. The flowers are said to be large, semi-double, of a beautiful deep violet red, deliciously fragrant. The beautiful foliage of the type has been preserved in this variety, which has not yet been named.—S.

— **IRIS PARADOXA.**—The *Botanical Magazine* for October gives an illustration (tab. 7081) of the above named Iris, accompanied by the following remarks:—"This very curious Iris has long been known in cultivation, but is still very rare. It closely resembles its better known neighbour *Iris iberica* (*Bot. Mag.* tab. 5847) in habit, leaves, and the inner segments of the perianth, which in both species vary in colour from white to lilac; but the outer segments of the perianth are quite peculiar and different from that of any other Iris in being reduced to a mere tip and narrow margin to the diffusely bearded claw. All the species of the sub-genus *Oncocyclus* are restricted to the arid regions of Western Asia, one or other of them extending all the way from the borders of Egypt northward to the Caucasus. Our drawing was made from a plant flowered by Mr. R. I. Lynch at the Cambridge Botanical Gardens last May. It is also flowered at Kew at about the same time."

— **EUCHARISES**, "M.D." on page 349, refers to the subject of this favourite stove plant and its insidious enemy the mite, the existence of which he formerly doubted but now admits. He thinks it now the attendant on bad management. Does he, then, believe in spontaneous generation? Some of the best *Eucharises* in the kingdom are to be seen at Cardiff Castle—leaves 7 to 8 inches wide, proportionally long and exceptionally thick, and plants flowering continually. They could only have been produced and maintained in their present superb condition by the best of attention to cultural details. Yet the *Eucharis* mite has been an unwelcome visitor there—brought, undoubtedly, with purchased plants, which were eventually and wisely destroyed. "M. D." should see Mr. Pettigrew's plants as I have done, and he would be obliged to admit that reckless watering rendering them unhealthy is not the practice at Cardiff; if it were the plants could not have grown from babyhood to their present dimensions and remarkable vigour. I have just returned from Cardiff, and was impressed with the high class gardening there.—A LONDONER.

— **TOMATOES.**—Can any of your correspondents say what variety of Tomato is known as Lord Sudeley's? I saw several plants of this variety bearing a heavy crop of fine fruits recently, but there is more of a rosy violet shade of colour in it than in Perfection and many other sorts; it grows to a large size and is firm and heavy. I know that Lord Sudeley's fruit farms are very extensive, and presume this variety is largely cultivated there; but as many friends who have seen this variety would like to grow it, the question arises, Under what name is it to be obtained? Is it a seedling raised at Tuddington, or a known variety? I have seen many instances of Tomato growing this season, and in nearly every case they have been grown in shallow beds of not over-rich soil; in fact, in most cases, in good loams chiefly, with Thomson's or some other manure used during the growing season. Judging from my own experience I am sure it is a mistake to grow Tomatoes in rich soil, and feed them heavily, and an important point is gained by planting out sturdy short-jointed specimens instead of drawn up long-jointed ones.—SOLANUM.

— **LAURUSTINUSES IN POTS.**—A correspondent observes:—White flowers are always in demand at Christmas. It is not every season that *Laurustinus* flowers can be depended on outdoors in December and January, but plants in pots removed to a cool house before severe

weather will be sure to give a succession of bloom for a lengthened period. The plants are best established in pots, but we have frequently lifted neat little bushes in October and November, potted them in loamy moderately rich soil, placed them under a wall or fence protected from the sun for a few days. They are then removed to a cool house, watered well, and the foliage sprinkled occasionally, the reward being heads of bloom very useful for decoration and cutting from during the dull winter months. The best form is the pyramid, as taking up less room than bushes; but standards are fine for breaking the monotony of flat even surfaces. All the plants require is to be hardened after flowering, to be planted out in good soil in an open situation, but sheltered from winds, and to cut the heads into shape before growth takes place, watering well if dry weather prevail when planting out; and they may be lifted again in autumn, for the lifting appears to increase their floriferous character. The flowers are much finer and more delicate when produced under glass than outdoors.

— **THE STRAWBERRY.**—Our present varieties of Strawberries are the cultured products of the native and other species of *Fragaria*. Few fruits have been more improved by cross-breeding, selection, and evolution; and yet, so long as those processes were confined to native species, little was effected but an enlargement of size in Wood and Alpine Strawberries, or Hautbois. So early as the beginning of the sixteenth century we read of the former being developed to the size of Mulberries, a development unknown to modern cultivators of the same species. It was not, however, until the introduction of *Fragaria chiliensis*, *F. grandiflora*, and *F. virginica*, that our present families of Pine and Scarlet Strawberries began to be moulded into their present quality and form. Some of these can now also claim a very respectable antiquity. The Old Scarlet has been grown in its present form for two centuries; the *Roseberry* or *Gravesend Scarlet* for at least a hundred years. Keen's Seedling was raised in 1820, and thirty years later the *Black Prince*, *Elton Pine*, and *Myatt's Eleanor*, and many others still in cultivation—the near progenitors of such fine varieties as *British Queen*, *President*, and a host of others. Considering that white varieties have existed from the earliest times, it seems singular that so few have been or are cultivated. A *White Alpine* and the *White Carolina* were extensively grown, and have been improved out of the garden by the *Bicton Pine*, a delicious white variety, well worth cultivating. Possibly some of these may have infused some of their white blood into such delicately tinted sorts as *British Queen*, *Dr. Hogg*, &c. But good white Strawberries are rare, and can hardly be said to be popular. There is probably more money made in Strawberries than in any other hardy open-air fruit. As much as £20 profit per acre has frequently been cleared from Strawberries, and it is no uncommon thing to hear of an acre of Strawberries being worth £100. Though a perishable crop, if picked and packed with care it travels safely by rail, and the smaller fruit can be made into jam on the spot, or transported in tubs to the large preserving houses. Picked fruit gathered over-night, and delivered in London or other large towns by the milk trains, generally commands a price of 6d. or more per pound. Thoroughly preparing the ground, manuring and planting, costs about £20 per acre; but the crop may remain three or more years on the ground without any great additional expense, and it would be difficult to name any other fruit that will yield larger gross returns and such liberal profits. The forcing of Strawberries also opens up an almost new and a profitable industry. Ripe fruit in March commands prices varying from 6d. per ounce. In the Royal Gardens of Frogmore about 100,000 pots of Strawberries are forced annually, and some commercial growers probably double or treble these numbers.—(*Cassell's Popular Gardening*.)

A NOTE ON PINE APPLES.

WE have been cutting fruit of *Charlotte Rothschild* and *Smooth-leaved Cayenne*, but were not able to keep the temperature high enough, consequently the fruit, though juicy, was not of superior quality. It will not do at this time of the year to ripen the fruit in a lower temperature than 65°, if it ranges between that and 70° all the better. The utmost caution is required in watering. In careful hands liquid manure benefits Pines very much, but if injudiciously applied much damage results to the fruit. If the plants are freely supplied with liquid manure up to the time of the fruit colouring, in all probability it will be black at the core. It is absolutely necessary to leave off using stimulants about the time the fruit takes its second swelling. If the soil is moderately moist water must be withheld from the time the fruit shows signs of colouring. In our beds, where the pots are not far from the

pipes, there is more danger of the roots becoming dry than there is when they are plunged in deep beds of moist leaves where the heat is kept up by fermentation. Suckers that are just established in the small pots in which they were potted early in autumn or late in summer are kept in a temperature of 55°; they do not receive much water. They might be grown on a little faster if necessary, but usually we have not room to pot them until May.

We have heard a little of new Pines within the last two or three years, but it will be some time before anything will beat the sorts we have grown for many years. The most recent of ours is the *Charlotte Rothschild*, but all points considered, although a most noble fruit, it is not equal to *Smooth-leaved Cayenne*. It is generally understood that there is a good and a bad strain of the *Cayenne*. We have had the fruits decay before they were ripe, but this has generally happened in spring when fierce sun has scalded the fruit, coming suddenly upon it after the dull dark days of winter; we usually just lay a sheet of newspaper over the crown to protect the fruits from injury. Is it not possible that this weakness in the *Smooth-leaved Cayenne* has led people to believe that there are two varieties? The *Queen* holds the same position amongst Pines that *Black Hamburg* holds amongst Grapes, and it is even now more valuable owing to the fact that nearly all the *St. Michael's Pines* are *Cayennes*, and these being imported in quantity at certain seasons very much depreciate the value of home-grown fruit. Good *Queens* are not only valuable for home consumption, but they always command a high price in the market independent of any glut from abroad. If it is intended to pot any plants in February the soil for this purpose ought to be put in a dry place, as it will not be in good condition for potting if exposed to the wet during winter. Good, sound, moderately clayey loam from an old common where Brackens grow freely answers well for Pines.—A. B.

PLANTING BULBS AND TUBERS.

THE summer bedding plants have remained effective rather later than usual, and this will necessarily delay the work of refilling the beds. The sooner, however, the bulbs intended for the mixed or herbaceous borders and other sites they are to permanently occupy are planted the better it will be for many of them. Early planting does not materially affect the time of flowering, but those in early are invariably the most strongly rooted, and afford a superior display of bloom. *Narcissi* and *Daffodils* are most effective when planted in groups of one variety only, the bulbs being disposed not less than 5 inches apart and fully 6 inches deep. A good position for them would be the second or third line in a mixed border, and all should be properly labelled, both in order to preserve the names and also to protect the bulbs when the foliage has disappeared. *Irises* vary considerably in height, and these also should be set well back in a border, or say somewhere near the middle. These may be planted in groups, the bulbs being disposed 9 inches apart and not less than 4 inches in depth. A little sharp sand surrounding these and bulbs generally favours a strong root action.

Anemones, of which there are several beautiful and quite hardy tuberous species, succeed very well in either small beds, in small patches, or even among fruit trees and bushes. Arrange them 5 inches apart and cover with 3 inches of light sandy soil. The latter condition is especially necessary where the soil is of a heavy clayey nature, and in this case it is also wise to defer planting till January. *Ranunculuses* should in no case be trusted in the open ground before January or as early in February as the state of the soil permits. Patches of *Triteleia uniflora* are very pleasing in mixed borders. Plant these near the front row, 3 inches apart and 3 inches deep. *Musk Grape*, and *Feather Hyacinths* are also somewhat dwarf, and the bulbs of these may be either planted in lines or patches, rather thickly, and about 3 inches deep.

Scillas are attractive for the Alpine garden and the front rows of mixed borders. These should be planted somewhat thickly and about 3 inches deep. *Snowdrops* succeed admirably in turf, the foliage dying down before it is necessary to mow the grass. Plant in patches 2 inches below the surface. *Crocuses* are effective in the front rows, and should be planted in a broad band and fully 4 inches deep. The *Winter Aconite* is usually the first to flower, and this does well in any moderately dry position, including rockeries. It is of very dwarf habit and should be planted in patches and about 3 inches deep. *Dodecatheons* (*American Cowslips*) and *Erythroniums* (*Dog's-tooth Violets*) also succeed in rather dry positions and light peaty soil—the rockery being a good position for these tiny gems. *Leucojums* to be treated similarly to the *Feather Hyacinths*, and if *Ornithogalums* are planted now they must be protected from severe frosts, a mound of ashes answering

for this purpose. *Chionodoxa Lucilæ* much resembles *Scillas*, and requires similar treatment.

Plant *Belladonna Lilies* as soon as received nearly close to a very sunny wall, a narrow border near the front wall of a forcing house being a capital position. Dispose the bulbs 12 inches apart and 4 inches deep. *Alstroemerias* ought to have a sunny and rather dry position where they will seldom be disturbed, fine beds being sometimes seen at the foot of dwelling house walls. Plant in patches 8 inches below the surface. If *Tulips* and *Hyacinths* are planted in mixed borders they are most effective in clumps, being disposed from 6 inches to 8 inches apart and 4 inches below the surface. Now is also a good time to plant *Fritillarias* and *Crown Imperials*, these being suitable for the back rows in mixed borders. They are most effective in clumps. It is not yet too late to transplant or purchase the beautiful *Lilium candidum*, which also should be arranged in groups along the back rows in mixed borders. This moves best with a tuft of leaves and roots intact. Arrange the bulbs 9 inches apart and bury them well below the surface without actually smothering the foliage.—W. I. M.

CHRYSANTHEMUM SHOWS.

WE shall be obliged to the secretaries of societies and others interested in the matter if they will send us brief original notes on the shows where this Journal is not specially represented. Local newspaper reports are frequently sent during the season, of which we can make but little use. All that we require are the names of the winners in the chief classes, the names of the varieties in the leading stands, and the general character of the show.

CHRYSANTHEMUMS IN THE WEST.

I HAVE just had a run westwards, and found *Chrysanthemums* well grown in four gardens, but the blooms from the early crown buds were fading. At Talygarn, South Wales, the pleasant seat of G. T. Clark, Esq., Mr. W. Wright, the gardener, has an admirably grown collection, not surpassed probably in the principality. At Cardiff Castle Mr. Pettigrew grows them in the free conservatory bush form, and splendid bushes they are, with rich foliage down to the pots, and scores of blooms on a plant for cutting by the armful. At Marston House, Frome, Mr. W. Iggulden has an excellent collection bearing exhibition blooms, but most from the crown bud are too early for the shows, though some grand examples of *Jardin des Pantes* may perhaps "keep." *Thunberg* is also exceptionally fine. The blooms from terminal buds are smaller, but firm, fresh, clear and beautiful. In the well-managed town garden of Mr. Bailey, Willow Vale, Frome, is a small collection, bearing blooms of the first quality, *Avalanche* perhaps the best of many others that are very good, but most of them fading now. They are a credit to the grower, Mr. W. Strugnell, who is an old pupil of Mr. Iggulden, and undoubtedly an excellent gardener.—A LONDONER.

AROUND LONDON.

THE majority of the *Chrysanthemums* around the metropolis are unusually early this year, and the first shows seem at present likely to have the best of the exhibits. There are, however, a few exceptions in which the blooms are later, and about right for the midseason exhibitions. We can only refer briefly to a few of the chief collections. Of the public displays one of the first to be opened was that in the Inner Temple Gardens, under the charge of Mr. Newton. A house near the embankment is devoted to the plants, which are arranged on a sloping bank with a path in front; and in quality of blooms and brightness of effect it is one of the best shows seen at the Temple for a long time. Japanese varieties predominate, and amongst the earlier blooms were uncommonly good examples of Mrs. J. Wright and *Edouard Audiguier*.

At Finsbury Park a wonderfully good show is provided by Mr. Cochrane, the plants and blooms quite up to the high standard distinguishing those at this Park. The house is 100 feet long and 18 feet wide, with a central group sloping to the path on each side. This is a convenient arrangement, but the house is scarcely large enough to do justice to the plants, and the larger structure which is likely to be provided next year will be a welcome improvement. All the best varieties in the principal sections are admirably represented. At Victoria Park Mr. Gibson has a spacious and substantial span-roof house filled with *Chrysanthemums* in two groups, the path being in the centre; and there, curiously, though only a short distance from Finsbury Park, the plants are much later—nearly a fortnight—and will last until nearly the end of the month. They are all healthy, sturdy specimens, bearing good buds, and the blooms they have expanded are capital examples of their respective varieties. Southwark Park also has a *Chrysanthemum* Show, and Mr. Bush well maintains his reputation by a capital display. In Battersea Park, too, Mr. Copping has a houseful of excellent plants,

hearing substantial blooms thoroughly creditable to his cultural skill. Another year we may expect still more of these public displays, and we might suggest Myatt's Fields, Camberwell, now under the charge of Mr. Moorman, and the Fawcett Park at Vauxhall, being laid out by Mr. Holmes, as very suitable places for such shows.

At the Crystal Palace, Mr. W. G. Head, the garden superintendent, annually grows from 6000 to 7000 *Chrysanthemums* for decorative purposes, and he has the latter number this year. The early and October varieties are chiefly depended upon, but over 100 varieties are grown, the best in large quantities. Many more varieties were grown at one time, but they are being steadily reduced as their qualities have been tested, and a still more critical selection will be made for another year.

Mr. A. H. Smee, of The Grange, Carshalton, is a well-known admirer of the *Chrysanthemum*, annually providing a large display which is thrown open to the public for some days. The gardener, Mr. Cummins, grows about 600 plants, which are arranged in one of the houses and produce a capital effect, forming a bank of bright flowers. The collection of varieties is a large one, most of the best old and new forms being included.

Amongst the trade displays of *Chrysanthemums* the principal are those of Messrs. H. Cannell & Sons, Swanley, Messrs. Laing & Son, Forest Hill, Messrs. J. Veitch & Sons, Chelsea, Messrs. Davis & Jones, Camberwell, and Mr. G. Stevens at Putney, all of whom devote several houses to the plants, and include amongst the ordinary stock some novelties of considerable merit.

TWICKENHAM.

The garden at Poulett Lodge, Twickenham, abounds in specialties, for Mr. W. Bates is an earnest believer in the old maxim that "what is worth doing is worth doing well," and he carries out the idea admirably in all he undertakes. A large collection of outdoor fruits gives good evidence of the best treatment by the healthy and fine fruit-bearing condition of the trees. Under glass we find Peaches and Nectarines, Grapes and Vines, all equally well grown, and miscellaneous plants of decorative value receive a good share of attention with satisfactory results. Amongst the latter must be included the *Chrysanthemums*, of which moderate numbers are grown, but they are most promising, and excellent blooms are expanding both of Japanese and incurved. Deep, substantial, clean, handsome, incurved blooms are noticeable that would grace any show board, and the Japanese are represented by large richly coloured blooms. If Mr. Bates were to turn his attention to growing flowers for exhibition purposes he would prove a formidable antagonist to some of the "old stagers," and we may yet hope to see him in the front ranks at the leading shows, though not this season.

TEDDINGTON.

A delightful walk from Twickenham on a brilliant moonlight night, and The Roselands, Teddington, is reached, where Mr. W. Furze devotes a large portion of his garden and houses to his great favourites the *Chrysanthemums*. Unfortunately their enthusiastic owner was absent, but by the kindness of Mrs. Furze we were permitted to see as much of the plants and blooms as candlelight would admit. The inspection was a very gratifying one, for it is always a pleasure to see well grown plants, and the gardener, Mr. Coombs, has given close study to the *Chrysanthemum* for some years with the best results. "Ah!" said my companion, "they have a secret here which I have not yet mastered. They grow the plants up to a certain stage, and then they grow the blooms." The fact is the plants are in smaller pots than are usually seen, the wood has not the slightest tendency to grossness—quite the reverse. In some cases it even looks thin, but it is firm, well matured, and evidently contains all that is requisite. The blooms come clean and free from deformity, building up steadily and regularly until the time arrives for the preparation for the show. Certainly some of the incurved blooms will require very little artistic aid to render them fit for the boards. The Japanese also are fine, and we regret that the demands upon our space this week will not permit an enumeration of the varieties, and where all are so good it is difficult to give a restricted list.

Weir Bank, the residence of Mr. J. P. Chappell, is nearly opposite The Roselands, and the love of *Chrysanthemums* would seem to have extended there, together with the skill necessary for growing them well. At any rate, Mr. Davies has an excellent display, and it is evident he is making rapid progress in the art which puzzles my friend—namely, "growing the blooms." He has a good selection of varieties, which are represented in nearly every case by handsome blooms, both of Japanese and incurved. The plants are arranged in a conservatory to form a sloping bank, the colours are effectively disposed, and the group altogether is a charming one.

CHRYSANTHEMUM MRS. ALPHEUS HARDY.

FEW novelties amongst *Chrysanthemums* have attracted so large a share of public attention as that named above, which was announced last year in the American papers, and made its appearance in this country during the present year. Elaborate descriptions were published, and the variety was proclaimed as the most remarkable ever obtained. It is almost needless to say that the accounts were received here with a certain amount of incredulosity; we always credit our American cousins with a tendency to exaggeration of the charms of their own possessions, and perhaps for that reason we are sometimes a little unjust in discounting their descriptions so severely. Some blooms were sent over here from the States, but they were not in good condition, and did

not serve materially to improve the reputation of the variety. Still nurserymen supplied themselves with a stock of young plants or cuttings as soon as they could be secured, and a member of the firm which

has been looked for quite anxiously, each grower trying his utmost to have the first blooms expanded. As announced last week, Mr. T. S. Ware of Tottenham has succeeded in accomplishing this task, and from

FIG. 47.—CHRYSANthemum, MRS. ALPHEUS HARDY.

sent it out came to England to act as agent, and, if necessary, to grow a stock of it. This looked as if they felt some confidence in its qualities, and so a good deal of curiosity was awakened here, and its flowering

a plant now flowering in the Hale Farm Nurseries, the illustration (fig. 47) was prepared.

The history of the variety may be briefly related as follows :—Mrs.

Alpheus Hardy is a well-known lady resident in Boston, who some time ago undertook the education of a young Japanese in America. When he was considered sufficiently advanced her protégé returned to Japan to engage in teaching, and as some return for the kindness he had received he obtained a collection of Chrysanthemums and forwarded them to his patroness. Amongst these was a variety that attracted some attention by its distinctness, and which first passed into the hands of Messrs. Fewkes & Son. This firm realised that they had secured a novelty of a very exceptional character, and when some other nurserymen wished to purchase it, they fixed a high value on the variety. After some negotiations, however, it is said that Messrs. Pitcher and Manda were induced to pay 1500 dollars, or somewhat over £300, for the stock. Every effort was made to increase this rapidly, and when distributed, young plants realised from 6s. to 10s. retail. Mr. T. S. Ware secured 500, which were soon multiplied, and several of these have produced flowers which expanded rapidly last week and are now at their best. It is somewhat strange that the majority of plants seem very late, and it had been expected by some in the trade that blooms would not be seen until after the show season; in fact it was believed to be a late variety. It is probable, however, that rapid propagation has somewhat weakened the plants, and that may account to some extent for the uncertainty characterising those grown this year; another season we shall expect very different results.

It will be asked, Do the blooms that have already opened possess all the characters ascribed to the variety when it was first announced? and the reply must be in the affirmative, for it is certainly one of the most distinct Japanese Chrysanthemums yet introduced. The blooms are of medium size, as might be expected on plants this year; the outer florets are half an inch broad and slightly spreading, but the majority are strongly incurved to the centre, thus exposing the under surface as in the ordinary incurved and the Japanese of a similar type. The colour is white, creamy yellow in the centre where not fully expanded, but that ultimately becomes white, as is seen in some more advanced blooms. The great peculiarity rests, however, in the abundant white hair-like outgrowths from the surface of the florets towards the points; these hairs are about a quarter of an inch long, very fine, in some cases divided at the tips, and thickly placed. In general appearance the bloom is very remarkable, and it has been rather aptly described in the American reports as resembling a white ostrich tip. The plant is of moderate growth, but produces suckers freely, and is readily increased. It has been remarked at Tottenham that the plant is not benefited by too generous treatment in the supply of manurial stimulants or by close disbudding. The best examples are those on a plant bearing six blooms, and where only one bloom has been left on each plant, liquid manure being employed freely to strengthen them, the results are not nearly so good. With sturdy cuttings for a start, however, it will be strange if some of our skilful exhibitors cannot produce extremely satisfactory results another season.—L. CASTLE.

AN AMATEUR'S CHRYSANTHEMUMS.

MR. G. R. PEERLESS, Park Hill House, Park Hill, Clapham, London, S.W., has a good display of Chrysanthemums in the conservatory attached to his residence. He has only been a grower for a very few years, but has got together an excellent collection of well grown plants. The greater part of his time is spent in business pursuits, but all his leisure is devoted to his favourite flowers, and to the deep interest and unremitting attention devoted to them may be ascribed his success. The plants grown number about 600, and with the best of the older varieties are associated most of the meritorious newer kinds. The queen of them all at the time of my recent visit was the lovely white Japanese Mrs. J. Wright, of which there were several finely developed blooms. It was too early to judge of the majority, but the following were all showing well:—Mr. H. Cannell, pale yellow Japanese; Stanstead White, Japanese; Sunflower, yellow Japanese; Duke of Berwick, creamy white Japanese; Avalanche, pure white Japanese; Charles Gibson, bronzy red incurved; M. J. Laing, reddish brown Japanese reflexed; Phœbus, rich yellow Japanese reflexed; W. G. Drover, white Japanese, striped lilac; Lady Trevor Lawrence, white Japanese, and E. Molyneux, reddish brown Japanese. The collection is not at its best yet. In due time it will be worth inspection by anyone.

CHRYSANTHEMUM SPORTS.

MESSRS. H. CANNELL & SONS, Swanley, send us blooms of the two sports from Mr. Bunn which were brought into notice last year, one in the north and the other in the south of England. The former, as represented by the bloom before us, has a deeper yellow ground colour, and more bronzy red tint in the upper surface of the florets; the other has a pale yellow ground colour, and somewhat of a dull rosy tinge on the florets. The difference is clearly noticeable, but the distinction is not great, and might be affected to some extent by the age of the blooms, one (the lighter of the two) being more advanced.

THE NATIONAL CHRYSANTHEMUM SOCIETY.

ON Wednesday last, October 30th, a meeting of the Centenary Sub-Committee of the above Society was held at Anderton's Hotel, Fleet Street, at 6 P.M. Present—Mr. R. Dean in the chair, Mr. W. Holmes, Mr. Briscoe Ironsides, Mr. L. Castle, and Mr. C. H. Payne. The object of the meeting was to consider an offer of the Royal Aquarium Company with regard to the Centenary celebration, and to decide whether this should be recommended to the General Committee for adoption. Mr.

Holmes stated that he had had an interview with Captain Molesworth, and that he had agreed, on behalf of the Company, to contribute £200 to the prize fund for the Centenary Show next year, provided it was held at the Royal Aquarium, and was of not less than four days' duration. No further conditions were imposed, and the offer being considered a liberal one, it was, after a short discussion, decided to report to the General Committee the desirability of accepting it. Mr. Holmes also stated that it would really constitute one of a series of shows now being arranged, extending from March to November, 1890, omitting one month only—namely, August, special attractions being provided for each show.

A General Committee meeting was also held at 7 P.M., when there was a large attendance of members, Mr. E. Sanderson taking the chair. After the transaction of the usual formal business, the report of the Centenary Sub-Committee was read and explained, and after a short discussion was adopted unanimously. The cost of carriage of specimen plants for exhibition at the November Show was considered, and it was represented that it proved a great deterrent to exhibitors, as the prizes were comparatively small. It was ultimately resolved to empower the Hon. Sec. to pay half the cartage expenses in such classes as far as the funds would permit, provided the exhibits were of sufficient merit, and that application was made within seven days of the Show. It was also decided that classes should be provided at the October Show of 1890 for Chrysanthemums, and Mr. Holmes was desired to make the necessary arrangements for the annual dinner next December. It was stated that special return tickets for Hull, *via* York, could be obtained on application to the Hon. Sec., and if ten or more were likely to travel by the 10.35 A.M. G.N.R. train on Wednesday, November 20th, a saloon carriage would be provided. Several members were elected, and a vote of thanks to the Chairman concluded the business.

CHRYSANTHEMUM SHOWS.

WE have received schedules of the undermentioned Chrysanthemum Shows, and we shall be glad to insert the dates of any not included, if the secretaries will forward us schedules of their respective Societies.

Market Harborough, Wednesday and Thursday, Nov. 6th and 7th.

Kent County, Wednesday and Thursday, Nov. 6th and 7th.

Portsmouth, Wednesday, Thursday, and Friday, Nov. 6th, 7th, and 8th.

Crystal Palace, Friday and Saturday, Nov. 8th and 9th.

Kettering and District, Saturday, Nov. 9th.

St. Neots, Monday, Nov. 11th.

Surrey (Peckham Public Hall), Monday and Tuesday, Nov. 11th and 12th.

Leeds Paxton, Tuesday, Nov. 12th.

National Chrysanthemum Society (Royal Aquarium), Tuesday and Wednesday Nov. 12th and 13th.

Kingston and Surbiton, Tuesday and Wednesday, Nov. 12th and 13th.

Wells, Tuesday and Wednesday, Nov. 12th and 13th.

Exmouth, Tuesday, Nov. 12th.

Torquay, Wednesday, Nov. 13th.

Bromley, Wednesday and Thursday, Nov. 13th and 14th.

Croydon, Wednesday and Thursday, Nov. 13th and 14th.

Bournemouth, Wednesday and Thursday, Nov. 13th and 14th.

West Kent (Bexley Heath), Tuesday and Wednesday, Nov. 12th and 13th.

Teddington, Putney, Chiswick, Cranbrook, and Birkenhead, Thursday, Nov. 14th.

Leicester, Eccles, Wellington (Somerset), and Cheshunt, Friday, Nov. 15th.

Bolton and Derby, Friday and Saturday, Nov. 15th and 16th.

Twickenham, Winchester, Liverpool, and Cardiff, Tuesday and Wednesday, Nov. 19th and 20th.

Rugby and Birmingham, Wednesday and Thursday, Nov. 20th and 21st.

Falmouth, Wednesday, Thursday, and Friday, Nov. 20th, 21st, and 22nd.

Hull (National Society's Provincial Show), Thursday and Friday, Nov. 21st and 22nd.

Chorley and Stockport, Friday and Saturday, Nov. 22nd and 23rd.

Pontefract, Thursday, Nov. 28th.

PLANTING FRUIT TREES.

AUTUMN has come again. Another season of growth is almost ended. Soon will the latest fruits be gathered and the fast-decaying foliage fallen; then, and often only then, comes the fruit-tree planter's opportunity before the soil, saturated by a winter's rainfall, has become sodden and cold. Mark this well, for success or failure in planting depends as much upon the time as upon the manner in which it is done. A correspondent ("J. H.") would seem to be aware of this, for he has come to us now to assist him in finding a remedy, or rather a preventive, for the failure of fruit trees. He says, "Last year I planted in a marly soil a large quantity of fruit trees, and about half of them are dead," adding in the true national spirit, "I intend trying again." Well done. "Try again" is the motto which points to success, and gladly do we come to your aid.

Now there are two faults in a marly soil which require correction before it can become suitable for the growth of fruit, and these are its poverty and its power of retaining superabundant moisture. The remedy for the first is a heavy dressing of manure,

and for the second drainage and a plentiful supply of coarse gritty matter, such as road scrapings, coal ashes, shattered bricks or stone chippings thoroughly mixed with the marl and manure, our object being to open up the soil to the action of the air as well as to drain and enrich it. It is of course desirable to treat the whole of the soil in this manner; but as this is a costly process it is customary to prepare stations for the trees, and to improve the condition of the remainder subsequently. Each station should be 6 feet square and 2½ feet deep, the bottom 6 inches being filled with broken stones rammed hard, and the 2 feet above filled with the prepared soil.

Drains of common 2-inch pipes should be made 30 feet apart and 4 feet deep, taking care to connect every station by a branch drain with the main nearest to it; for when stations are prepared in clay, or any substance of a compact adhesive nature, if they are undrained they become just so many death traps for the roots, owing to the accumulation of stagnant water. In my own practice I am not content to make a branch drain to the side of the station, but continue it right across the bottom, laying the row of pipes upon the hard-rammed stone. As a general rule it may be taken for granted, that when the soil in which fruit trees grow rests upon a deep compact subsoil drains will do good, but when the soil is shallow and has a substratum of rock, chalk, or shattered stone immediately beneath it (a natural drain), then of course artificial drains are uncalled for, and would, indeed, prove injurious.

Let the planting be done in November, pruning off all bruised roots, and shortening all leading shoots to about 9 inches. Do not bury the roots deeply, but keep them within 6 inches of the surface, spreading every one of them out carefully to its utmost length, treading the soil so that none of the roots lie at all loose in it. Cover the entire surface of the station with 3 inches of rough half-decayed manure immediately after planting, and fasten the tree securely with wire and stumps so that it may never be swayed by the wind, for if the roots and stem become loosened in the soil the tree will not grow and there is much risk of its dying. Always plant quickly, or cover the roots with soil when you receive them from the nursery. The effect of exposing the roots to the air is so pernicious that many a tree has been lost through it. Take care that the manure mixed with the soil is old and quite decayed, or it may contain the spawn of fungi, which is also found in decaying wood and leaves, spreading thence over the roots of the tree and killing them.

Watch the trees carefully during the first season of growth after the planting. See that they do not suffer from drought. The surface-dressing of manure will act as a tolerable safeguard, but two or three thorough soakings of water or sewage are of material assistance to the growth and health of the tree in a dry season. See also that any fastenings of string or wire are loosened in time to prevent harm to the bark, which swells very fast upon a healthy strong-growing young tree.

Given healthy trees and due attention to these hints there ought not to be a single failure. Every point and detail mentioned is, however, of equal importance with the rest; and I must insist upon no negligence in any respect, for failures often arise from inattention to some matter apparently trivial in itself but of vital importance in its influence upon other things, and our correspondent will probably find that his lamentable failure was caused by inattention to some so-called trifle.—E.

SEASONABLE NOTES ON USEFUL PLANTS.

AMASONIA PUNICEA.

SOME care is needed not to check this plant in its present stage of growth. It must not have too much water at its roots, or they will perish, especially if the temperature in which it is grown is rather low. To do it well it should have a temperature of 65°, and if practicable a gentle bottom heat, which induces it to lengthen the brilliant crimson bracts and racemes of creamy white flowers. It grows freely during summer, but when growth is completed it is easily checked, and the flowers do not open well in a temperature that falls below 60°. It will do in this temperature, but where the higher one can be maintained all the better.

ANTHURIUM SCHERTZERIANUM.

Plants that have completed their growth should be removed from the stove to any structure where an intermediate temperature can be maintained. While in this position supply water carefully; in fact, it is desirable to keep the soil somewhat dry. The roots are very liable to decay if the compost about them is too wet while the temperature is low. Cold draughts must not be allowed to strike upon the plants. A few weeks' rest in a lower temperature is beneficial, and stove heat afterwards will soon bring them into flower. During the early months of the year few plants are more

serviceable in the stove for decoration; their scarlet spathes showing to great advantage.

ANTHURIUM ANDREANUM.

Strong plants raised in the spring, and in 6 and 7-inch pots, with a large spathe from each rising above other plants are conspicuous at this season. For associating with other plants in stoves that have to be kept attractive during the autumn and winter few plants are more effective or useful than this Anthurium. No sooner does one spathe disappear than another is produced. A few large plants for the centre of large houses are also very telling. There are many varieties, some of which are scarcely worth growing. The best plan is to select a good bright-coloured variety with large spathes, and grow it upright until it is 4 or 5 feet high, and then cut up the stem in spring. One good bud is only needed for each plant—that is, portions of stem with about two joints. The old stool will break freely again from the base.

CLERODENDRON FALLAX.

The earliest plants that were raised from seed will quickly come into flower if they are given stove heat—in fact, these plants will soon go back in a lower temperature than 60°. When the plants come into flower select one, and place it in the dryest position that can be found for yielding seed. The chief reason why the flowers do not set freely when the plants are grown in the stove is because the atmosphere is too moist.

APHELANDRA AURANTIACA ROEHLI.

Some of the most forward plants are coming into flower, and as these are much better raised from seed than cuttings, and grow with greater freedom, a few plants should be selected for seed-bearing. These must be placed on a shelf, or where the atmosphere is a little dryer than in the stove. Under these conditions they produce seed freely, but when the seed is ripening it should be collected daily, because it is soon distributed about the house. Plants that flower about February generally bear seed better than those that come into flower now. From plants flowering at that period we have lifted large quantities of young plants that have sprung up in the gravel and by the side of the walks. It is not safe, however, to rely upon a stock of plants being raised from self-sown seed.

CALADIUM ARGYRITES.

The leaves of this small-growing Caladium are always useful for associating with flowers. The tubers of a few of the plants that ripened early may be started into growth in brisk heat. The tubers should be placed singly in small pots, and plunged in brisk bottom heat. If grown only for their foliage a number of tubers may be placed in 5-inch pots. They start quicker and better in small pots with only a small quantity of soil about them.

CYPERUS DISTANS.

Strong plants in 5-inch pots raised from seed in spring and now in an intermediate temperature may be brought forward in succession by introducing a few into a temperature of 65°. Where furnishing is done on a large scale few plants are more useful. They are easily grown, and will bear cool house treatment until the end of October—in fact, they will do very well through the winter in a house that does not fall below 45° to 50°. Strong plants grow quickly in heat, but care should be taken to harden them before they are used in rooms and other similar positions.—B. N. G.

HORSERADISH CULTURE.

FOR the last two years I have practised the following annual routine of culture with Horseradish, and find it succeed perfectly. As soon as the leaves are off the plants in October or November we take out a trench at one end of the bed, as is usual in ordinary trenching, and by means of fork and spade turn over the whole of the bed down to the clay, carefully picking out the roots as whole as possible, and manuring as the process goes on. The bed is then made level ready for replanting. The roots are next looked over; all that is fit for kitchen use are dressed and laid aside for that purpose, and all the long thin roots of the thickness of a quill stripped of all side roots are laid in bundles for replanting. With a long dibber (or an ordinary Dahlia stick will do), make holes 18 inches or 2 feet deep, 6 inches apart, and 1 foot between the rows. Into each of these holes we drop one of these long roots, and then fill the hole up with fine dry soil from under the potting bench. These make good useable roots the first season, but of course if they were left for two seasons they would be much better. This annual planting has many advantages. In the first place, a very small bed will grow sufficient for the supply of most families. This struck me forcibly on entering a very old kitchen garden a few months ago, where was to be seen a bed of

Horseradish some 15 yards long by 5 or 6 wide, which apparently had not been disturbed, except in digging roots for use, for fifteen or twenty years. In contrast to this we have dug from a bed 15 feet by 8 sufficient good roots to supply an ordinary family for twelve months. In the second place, the ground is being cultivated. It is annually improving; and the plants being in rows, it can be kept clean by means of hoeing, the same as any other crops, instead of becoming a nest of weeds, as is too often the case; for it is no uncommon thing to find weeds seeding in the Horseradish bed in gardens where they would not be tolerated anywhere else. In the third place, there is no such thing as shouldering a pick when grim Jack Frost resists the spade in the gloomy winter months. The roots are laid regularly in layers one above another with soil between, and covered with soil. A little litter keeps out frost and mice. It is always accessible without the aid of either pick or spade. Would anyone who is acquainted with the system practised by those who grow it for the market favour us with an outline of their mode of producing the fine clean roots which they send to market?—R. P.

GREENHOUSE PLANTS.

HERBACEOUS CALCEOLARIAS.

CALCEOLARIAS are growing rapidly, as it is during the cool and moist months of autumn that they make good progress. Our plants are still in cold frames, and we are thinking of removing them to a cool brick pit facing south, where they will remain as long as the mild weather lasts. We have no set time for repotting, as it can be done at any time right through the winter. The principal point is to guard against the plants becoming root-bound. When the plants are grown on so that they are ready for their largest pots in October or November they get checked in growth. A cool greenhouse is the best place to winter the plants in. Keep them near the glass, and take care not to expose them to cold draughts or an arid atmosphere. Green fly is the most troublesome pest the Calceolaria has to contend with, so the house or pit should be fumigated every fortnight. So far our plants have not needed fumigating, but when removed to their winter quarters it will not be delayed, as prevention is better than cure.

DOUBLE PRIMULAS.

The earliest flowers are now unfolding in a pit where the night temperature ranges about 55°. Careful watering is necessary, and the plants must also be exposed to direct light, when these useful plants will well repay the cultivator for their trouble. Too much cannot be said in praise of these useful winter-flowering plants. Where "buttonholes" are in daily demand these are the plants to grow. The old Double White and its fimbriated variety, with Marchioness of Exeter, Miss Eva Fish, and Carminata, are the varieties we find the most useful.

CINERARIAS.

These should not be allowed to remain in cold frames any longer, as the foliage is apt to suffer from damp. A cool greenhouse or pit is the best place to winter them in. Cold draughts through side ventilators must be guarded against, as this is apt to cause the foliage to curl. Insects must also be kept in check with slight periodical fumigation. If the main plants are in their largest pots by the end of January it will not be too late, as we find those late potted keep their lower foliage well. But they must not be allowed to become root-bound upon any consideration before being placed in their largest pots, as this will not prevent their sending up a spindly flower stem. Too rich soil and loose potting must be guarded against, as they cause large flabby foliage, and the plants collapse with the least exposure to sun. Four parts of turfy loam, one part each of leaf soil and decayed cow manure with a little sand, we find a suitable compost both for the Cineraria and herbaceous Calceolaria.—A. YOUNG.

PLANTING YOUNG VINES.

HAVING read Mr. Bardney's remarks on planting young Vines without disturbing the balls or disentangling the roots, I was afraid we had done entirely wrong, as we had just planted two new vineries here (or about that time). I will now state how we performed the planting, and will then leave it for the readers of the Journal to decide which way is the better.

We planted the Vines on February 19th of the present year. The canes having been previously cut down to 9 inches long they were turned out of the pot, and all the soil shaken from them. The roots were then disentangled and spread out evenly in the new soil, and covered over in the usual way. They then received a gentle watering, and afterwards started gradually into growth, increasing the temperature as the season advanced, nothing being done whatever to force them

on too fast, a stout sturdy growth being aimed at. Air and water was given when found necessary, and now we have well ripened canes 23 feet long and 2 inches in circumference, nearly to the extremity of the canes.—J. L. H.

DRIVES AND WALKS.

It has been said that it is far better that no approach or other drive should cross the lawn in front of a country house. But of course the arrangement which is ideally best cannot always be made. In many cases where the road can be kept away from the immediate vicinity of the house front, it will have to pass it at a greater distance. The road may then be masked by low plantations, which will, at least, be less disagreeable to the eye than the line of gravel. But plantations will often be undesirable as obstructions in what ought to be a simple extended view, or a broadly treated landscape. It is better, when possible, to sink the road, or to raise the lawn in a gentle slope towards it to such a degree that the eye will not perceive it, so that the stretches of lawn on its hither and further sides will seem to unite without a break.

If the place is so large that the house is not seen until after one has entered the approach road, attention should be paid to the first view thus afforded. There is much in initial impressions, and a house may never redeem itself wholly in a visitor's eyes if it fails to do itself justice when they first light upon it.

With regard to walks, the same general principles hold as with regard to drives. There should be no more of them than are needful; they should neither be so straight as to lack beauty nor so meandering as to lack ordinary directness, and they should be as narrow as convenience will permit, for gravel streaks are not charming objects in themselves, and the greater their breadth the more they decrease the apparent size of the place. They should not be so narrow that two persons cannot pass with comfort, except in retired situations, where pedestrians will certainly be few; but anything in excess of this should be studiously avoided. A walk 6 feet wide, where one of three would have sufficed, will dwarf its surroundings to a much greater degree than most owners realise.

A lawn can be injured almost as much by foot-paths as by drives when they cut across it. A properly kept lawn is as delightful to walk upon as to look at, and, in our dry summers, the days are few when it will be too wet even for a lady's shoe. Of course there may be cases when some distant object—a summer house that is constantly used, a boat house, or tennis court—will so constantly attract the feet that, unless a walk be provided, a ragged path will be worn across the grass. Then, a made walk is naturally better, for anything is better than a look of untidiness and neglect in grounds which ought to be carefully kept. But it should, if possible, be carried around the lawn, and, if this is not possible, its presence should be accepted as a disagreeable necessity.

Paths should never be made across a lawn simply to give access to flower beds, for the flower beds themselves have no business there. A lawn is a place for grass. Its object, whether it be large or small, is to afford a simple sheet of verdure to delight the eye with its reposeful breadth, and to supply a proper foreground for the plantations beyond it. To spot bright beds about is to ruin its peacefulness and its unity. There are thousands of country places in America, from large estates to suburban villas, which would be immeasurably improved could all the flower beds on the lawn, all the fountains and vases, and all the paths—leading nowhere but back to the house again—be once and for all turfed over. Flowers can usually be introduced in sufficient quantities in other ways—scattered among the shrubberies, or arranged in massed beds behind the house or in borders disassociated from the lawn. Or, if they are the prime consideration, and the place is not large enough for a lawn and a flower garden both, it is better to give up the lawn altogether and arrange in front of the house an old-fashioned garden, with as many beds and walks and Box hedges as the space will allow. Such a design is consistent and sensible, and may be made very pretty, while the more common device of trying to unite a lawn and a flower garden is illogical, and can never result in anything but an artistic monstrosity.

If there is a lawn, large or small, care should be taken that no walk, as well as no drive, runs between it and the house. Let the grass come up to the house foundations, and unite the two by planting a few Vines and shrubs. Then the house and its site will be connected and harmonised; the walls will seem to spring from the soil almost like a natural growth, and the picture seen from the lawn will be as charming as that which the lawn presents when seen from the house. Whether there are mere doorsteps, or a porch, or a piazza, no path is needed, for this entrance should be used only by those who wish to stroll upon the lawn or to cross it to some spot not otherwise accessible. And even on those sides of the house where a path is needed it should not be allowed to run close to the walls. Sufficient space should be reserved for planting against the walls, and thus, if the further side of the path is properly planted too, from a little distance the eye will see only the masses of verdure which connect the house with the landscape about it.

Although curving roads and walks are best in a place of any size, straight ones should usually be preferred in a small villa lot. Then every inch of space is valuable, and of course a straight path occupies less ground than a winding one. The straight lines formed by the house and the street cannot be for a moment forgotten, and it is, therefore, good art to accept them as the basis of the whole scheme and make the paths within the gates correspond with them. Then, too, there should be no drive at all unless there be a stable behind the house. In this case it is best to leave the front free and

carry the road in at the end of the lot to a door in the side of the house whence it may continue to the stable yard. Place for a lawn is thus reserved in front, and the line of gravel will be least conspicuous from the principal windows. But it is better, when there is no stable, to sacrifice comfort a little in the interests of beauty—to leave the carriage in the street and let but a narrow pathway approach the house. The sacrifice will be a small one, and the gain in the aspect of the place as a whole may easily be great.

The suggestions have not been made with the idea of making "every man his own landscape gardener." On the contrary, they have been written to show how many things must be considered in the building of the simplest country house, or the designing of the smallest place; and how desirable it is, therefore, that the aid of an artist should be called in at the outset.—(*The American "Garden and Forest."*)

ROSES OF THE FUTURE.

Now that the Rose catalogues are mostly sent out it may be interesting to have indicated some of their promises for the future. Mr. George Paul announces Dowager Duchess of Marlborough for May, 1890, his prize seedling of 1888, old Auguste Mie, but perfected. The globular shape of that old friend was very admirable, and might be revived with advantage. There are also three of German raising brought forward, all apparently descended from the Gloire de Dijon, of which Progress seems the most remarkable, with Gloire de Dijon leaves, bright carmine.

The others, Kaiser and Kaiserin Frederick, are more yellow with a reddish tinge. His J. D. Pawle of 1889 has already made its mark. Rich velvety crimson with maroon shading is its description. Mr. Bennett's Cleopatra had a first-class certificate in 1887. Somewhat after the style of Elise Vardon is perhaps as high commendation as a Tea could have. It would appear a worthy addition to Princess of Wales, Her Majesty, Lady M. Fitzwilliam, and others of his, which stepped at once into the very front rank of exhibiting Roses. Mr. Bennett offers Maid of the Mist, a sport from Lady M. Fitzwilliam. Mr. G. Paul has already given us a similar sport—i.e., Lady Alice.

White Roses appear in the ascendancy, and we can hardly have too many of such high class varieties. We have also Mr. Prince's new white Souvenir de S. A. Prince, and White Perle, offered by Messrs. Curtis and Sanford, an American sport from that admirable yellow Tea Perle des Jardins. Messrs. Mack & Son are able to tell of the triumphs of their Sir Rowland Hill, the darkest Rose in existence. They also recommend Earl of Dufferin, to my mind one of the very best and largest of our new Roses; rich velvety crimson, shaded with dark maroon. Strange to say it would have been in former years, but nowadays in French Roses there is nothing that comes very prominently forward. The various Rose catalogues are admirably compiled, and present interesting and instructive reading, besides many temptations, but of all I must confess to a leaning towards one from the West, perhaps because of the charming Rose portraits with which it is embellished.—A. C.

THOMAS'S PHOSPHATE.

WILL some kind horticulturist inform me whether he has ever used Thomas's phosphate in the cultivation of Roses especially, in what quantity he applied it, and at what time, autumn or spring, and how; whether as a top-dressing or dug in, and with what result?—RUSTICUS.

NAMING FRUITS AND VEGETABLES.

Now that nomenclature is attracting attention the following report may possess some interest.

The Association of American Agricultural Colleges and Experiment Stations at its Knoxville meeting in January, 1889, appointed a Committee to devise methods for co-operative work in horticulture, and especially in testing new varieties of fruits and vegetables. This Committee called a meeting of station horticulturists at Columbus, Ohio, in June, 1889, for consultation. At this meeting a committee on the nomenclature of vegetables was appointed. The report and rules for nomenclature formulated are as follows:—

REPORT.—The Committee believe that all interests will be subserved and that dignity will be secured by simplicity and good taste in the nomenclature of kitchen-garden vegetables. To this end they have formulated a series of rules on the naming of vegetables by authority from the Convention of Horticulturists of the Experiment Stations held in Columbus, Ohio, on the 13th and 14th of June last.

Reform in this department of horticultural nomenclature should be prosecuted as vigorously and successfully as it has been in the nomenclature of fruits at the hands of the American Pomological Society. The Committee are confident that brevity, accuracy, and good taste in the naming of vegetables are perfectly compatible with the purposes of trade, and therefore solicit co-operation in this work not only from all

writers upon horticultural topics, but also from all dealers in garden seeds and supplies.

A name is bestowed upon any plant solely for the purpose of designating it. It is not the province of a name to describe the plant. All description is properly a part of the text. This description should present a characterisation of the variety rather than a mere list of adjectives intended to catch the eye. The Committee desires to suggest that a variety never be described under a name which is accepted as a synonym. If the synonym is used as a leader, it should stand only for the purpose of making a reference to the proper name; as, Ivory Ball. See White Apple.

RULES.—1. The name of a variety should consist of a single word, or at most of two words. A phrase, descriptive or otherwise, is never allowable, as Pride of Italy, King of Mammoths, Earliest of All.

2. The name should not be superlative or bombastic. In particular all such epithets as New, Large, Giant, Fine, Selected, Improved, and the like should be omitted. If the grower or dealer has a superior stock of a variety, the fact should be stated in the description immediately after the name rather than as a part of the name itself; as, "Trophy, selected stock."

3. If a grower or dealer has procured a new select strain of a well-known variety it shall be legitimate for him to use his own name in connection with the established name of the variety; as, Smith's Winningstadt, Jones's Cardinal.

4. When personal names are given to varieties titles should be omitted; as, Major, General, Queen.

5. The term hybrid should be used except in those rare instances in which the variety is known to be of hybrid origin.

[A hybrid is the product of true species. There are few, if any, instances of true hybrids among common garden vegetables. The union of varieties gives rise to a cross.]

6. The originator has the prior right to name the variety, but the oldest name which conforms to these rules should be adopted.

7. This Committee reserve the right in their own publications to revise objectionable names in conformity with these rules.

CULTURE OF ERYTHRINA CRISTA-GALLI.

THIS, "the Coral Plant," introduced over a century back, is now but seldom seen, except in the large gardens of places of some note. Few plants are more accommodating. It may be flowered either as an early stove or late greenhouse plant on a conservatory wall, or even in a warm open border with a little care. It may be had in bloom early in spring by placing a plant in the stove not later than Christmas, and a succession may be kept up by starting at intervals. In the greenhouse, if kept rather close when beginning to grow, the plants will bloom freely about midsummer, while if started in a common hotbed in March, and then gradually hardened off, they will bloom in May and June.

It is best to commence with young plants, and give liberal treatment to encourage luxuriant growth, for the stronger the growth and the finer the foliage the stronger will be the crown of the plant, and consequently the more vigorous the supply of shoots. In the following season the plants should have large shifts, and a free supply of liquid manure, with plenty of drainage. The most suitable compost I have always found to consist of three parts fibrous peat, two of fibrous loam, and one part a mixture in equal quantities of leaf mould, well-decayed sheep-dung, and silver sand.

A gentle bottom heat is very useful in obtaining a good supply of roots. The temperature of the house need not be more than about 60°. When the plants have made some progress let air be given to prevent the shoots being drawn up, and give them a good syringing every evening. Erythrina is one of the finest plants I have ever grown against a conservatory wall, where it flowers beautifully. If grown in the flower garden, the best plan is to take the plants up at the end of autumn, keeping them out of the reach of frost, and nearly dry till spring.—G.

THE CANNON STREET DINNER.

BEING an old Oddfellow, and anxious to get as many as I could to our annual dinner in June last, I had to promise in one case that I would in return go to the United Horticultural Benefit Society's annual dinner. Now not being a gardener I did not look forward to the 23rd of October with any great amount of interest, and it took some little coaxing for me to make a start on that afternoon. But to my delight on reaching Cannon Street Hotel I found that the large hall devoted to the gardeners' feast could seat comfortably 150 persons, the tables all decorated with vases, epergnes, and the choicest of table plants, some thousands of plants being used in its adornment, with about 100 dishes of splendid fruits, groups of specimen plants in the corners, making the whole room look like a veritable fairyland.

At the appointed time, half-past five, the jolly gardeners and friends began to arrive, and then you could see by the friendly greetings and handshakings the true meaning of their motto, "Union is strength." At six o'clock the dinner was served in splendid style, and followed by a grand programme of songs and toasts and plenty of fruit. The time seemed to slip along too quickly, and brought one of the most enjoyable evenings to a close anyone could possibly wish for. I should say proud is the man who belongs to such a Society, thus making a provision for times of sickness and distress, and having the pleasure once a year, (members living within fifty miles of London), of coming up in rare form.

to celebrate its annual dinner, a meeting to be remembered by every one who had the pleasure of being present.

In the course of the speeches I noticed two grand points of the Society—viz., that should a member be unable to keep up his subscription of 6d. or 9d. per week, what he has paid is not lost, but at his decease or on attaining an old age he has what is due to him. Another thing, should any honorary member paying one guinea a year or more unfortunately get into straitened circumstances he is helped from the Society, and as we never know what the future may bring forth I consider that a grand provision. I was very pleased to hear that over twenty friends gave their names to become honorary members. It was said during the evening that of the 300 members on the books not one was on the sick list, speaking well for the gardener's occupation, and indeed judging by the splendid flowers and fruit displayed it must be a very pleasant work as well. One of the Committee invited any member to attend their meetings held at the Caledonian Hotel on the second Monday in each month to see the way in which they conduct their business. Their dinner arrangements were certainly carried out in a perfect manner, and great credit is due to them.

The chairman spoke of a convalescent scheme, which would be a grand thing if in accordance with the rules, and he promised a donation of £25 to form a nucleus of such a fund, which all must consider a very handsome act on the part of the worthy gentleman who occupied the chair. I should say that it will not be long before every gardener under the age of forty-five will avail himself of such a society, and instead of 300 we shall see 3000 members, the only qualification being a doctor's certificate of good health, with age and address, forwarded to the Secretary, 9, Martindale Road, Balham, at the next meeting they are proposed and seconded, and become members of this excellent body of men, banded together for mutual good. I hope I have not taken up too much of your valuable space.—A WELL WISHER.

LEAD CAPPED GLAZING.

VARIOUS methods of glazing without putty have been devised from time to time, and amongst them the plan of Mr. T. Page of Banbury

FIG. 48.—LEAD CAPPED GLAZING.

is worthy of being placed before our readers. The annexed illustration will render the method plain to all. A A is section of the bars, either of wood or iron; B shows section of the glass between two adjacent bars; and C D, C D that of lead capping; at C illustrating the flange turned up to receive the glass, and at D the lead turned down on the glass to secure it. Any section of bars can be used, either in wood, iron, or other metal. The lead being self-sustaining when rolled on to the bars, without the use of nails to fix the same, enables iron to be used as easily as wood. The glass can be quickly inserted, and is said to be held firmly against wind and will not slip.

THE SOURCES OF THE NITROGEN OF VEGETATION.

(Continued from page 385.)

THE authors in conclusion point out that, since experimenting in free air instead of in closed vessels, as in Boussingault's and their own researches, has become common, there has been a great accumulation of evidence tending to indicate the fixation of free nitrogen. The modes of explanation of the gain of nitrogen are: that it has been absorbed from the air, either by the soil or by the plant; that there is fixation of free nitrogen within the soil by the agency of porous and alkaline bodies; that there is fixation in the soil by the agency of electricity; that there is fixation by the plant itself; that there is fixation under the influence of micro-organisms within the soil. The balance of recorded evidence is undoubtedly in favour of the last-mentioned mode of explanation. "Indeed, it seems to us," say Lawes and Gilbert, "that, if there be not experimental error, there is fixation of nitrogen within the soil, under the influence of micro-organisms, or other low forms of life." But they think that final judgment must be held in abeyance for the present. Most of their own and Boussingault's previous experiments excluded, by their conditions, the action of electricity or of micro-organisms.

They then consider some of the facts of agricultural production in their bearing on the question as to how far the establishment of the reality of the fixation of free nitrogen is necessary to the solution of problems of agricultural production. They point out that the loss of nitrogen in ordinary farm practice is not so great as Berthelot and others have assumed; the annual loss of nitrogen by cropping in Great Britain, for example, is probably under 20 lbs. per acre. The loss by drainage may in some cases be considerable, and in special cases there may be loss by evolution of free nitrogen. Probably the loss of free nitrogen from the plant itself during growth, which is assumed by some

does not occur. The accumulation of combined nitrogen which occurs in the surface soil of pastures is not conclusively explained, but it may have a subsoil origin, and this assumption has as much evidence in its favour as that it has an atmospheric origin. In the soil and subsoil of Rothamsted, to a depth reached by the deeper-rooting plants, there is 20,000 lbs. of combined nitrogen per acre; in very many of the soils of this country there is more, though in some less than this: the accumulation of nitrogen in the surface soil may well be due to nitrogenous crop-residue, the nitrogen of which comes principally from the subsoil. Again, the natural fertility of most soils is without doubt due to the accumulation of ages of natural vegetation with little or no removal; and the amount of nitrogen even now brought into combination under the influence of electricity, over a given area, would be sufficient, with growth and little or no removal, to account for the accumulations in natural prairie or forest lands even of the richest.

The Rothamsted experiments have shown that after growing crops for many years without nitrogenous manures there has always been a diminution of nitrogen in the top soil; this has been found to be the case with diverse crops, including gramineous, cruciferous, chenopodiaceous, and also leguminous crops, and with a four-course rotation of crops. There has not been compensation of nitrogen from the air, or at all events to the extent of the annual losses. "The agricultural production of the present age is, in fact, as far as its nitrogen is concerned, mainly dependent on previous accumulations; and as in the case of the use of coal for fuel there is not coincident and corresponding restoration, so in that of the use or waste of the combined nitrogen of the soil, there is not evidence of the coincident and corresponding restoration of nitrogen from the free to the combined state."

CHRYSANTHEMUM SHOWS.

CHRYSANTHEMUM CENTENARY CONFERENCE AND EXHIBITION AT CHISWICK.—NOV. 5TH AND 6TH.

ENOUGH has perhaps been said in preliminary announcements of the Chrysanthemum Centenary at Chiswick to indicate its character and objects fully, but as these were tersely summarised in the schedule it may be well to recapitulate them. "The object of the Conference is to get together as large and as representative a collection of Chrysanthemums of all descriptions as possible; to form an exhibition of all subjects pertaining to the Chrysanthemum, whether in its botanical, its horticultural, its literary, or its artistic aspects; and to bring together for the purposes of reciprocal information and fellowship all those interested in the Chrysanthemum and its culture." The Society were, in fact, following the plan of the Rose Conference held in summer in endeavouring to find something of interest for all Chrysanthemum lovers, growers and non-growers; those interested in this section or in that, or in no section at all. The Chairman of the Committee was Mr. T. B. Haywood of Reigate; the Secretary, Mr. E. Molyneux, Bishops Waltham, both men of influence in the Chrysanthemum world. The schedule had been arranged in a very comprehensive manner, and nothing that forethought could provide was wanting to make the Conference a great success. Bearing this in mind, it was satisfactory to note that the gathering was a really successful and interesting one. Competition was lacking with specimen plants, but the groups formed a grand feature, nearly filling the large vinery, and the side stages were well filled with cut blooms. Altogether they presented a splendid display, seen at their best under the lofty Vine-clad roof, and with a brilliant sun shining down upon them.
